Osmotic pressure in plants. IV. Constituents and concentration of the sap in the conducting tracts, and in the circulation of carbohydrates in plants. H. H. DIXON AND W. R. G. ATKINS. *Sci. Proc. Roy. Dublin Soc.* 14, 374-91(1915); cf. *C. A.* 4, 2655; 8, 198.—Sap pressed from the branches and roots of various trees during different months of the year was examd. cryoscopically, electrically, and chemically. The f. p. of the nonelectrolytes, mostly carbohydrates, was found by detg. the f. p. of the original sap and the cond. of the soln., then detg. the f. p. of a soln. of KCl having the same cond., and subtracting this value from the original f. p. In this way the concn. of carbohydrates is found to be from 1.5 to 6%, depending on the sugar present. Sap so obtained is contaminated, as pressure bursts the cells in the wood, and forces out chromogen, and an oxidase. The sap is acid to litmus. The wood was therefore centrifuged, and a colorless neutral liquid obtained, which, however, depressed the f. p. as much as a 0.25% soln. of glucose. Sap centrifuged from *Acer pseudoplatanus* in August, was found to contain carbohydrates. The mol. concn. of carbohydrates in the transpiration stream of deciduous trees is greater than that of the salts. As the stream rises, the amt. of dissolved electrolytes diminishes. This diminution is probably due to the fact that they are used in the various processes of metabolism. A theory of the function of the living elements of the wood is given. V. Seasonal variations in the concentration of the cell sap of some deciduous trees. *Ibid* 445-61.—Samples of plant tissue from the roots and leaves of 3 different trees were collected throughout the year frozen in liquid air and the sap pressed from them. The f. p. and the cond. of this sap were detd. and the lowering due to carbohydrates and electrolytes was then calcd. During the period when the leaves were on the tree, the osmotic pressure rose from 13.5 to 16.5 atms., this rise being due to increased concn. of electrolytes, but at least $\frac{1}{3}$ of this pressure was due to sol. carbohydrates.

Fumigation experiments to determine the effect of highly diluted sulfur dioxide on a growing grain crop. A. E. WELLS. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 213-307(1915).—W. reports in detail with numerous illustrations, tables, and notes a series of fumigation expts. in which the number of fumigations, time, concn. of SO_2 , humidity, and temp. were varied. The S content of foliage fumigated with SO_2 was in all cases greater than that of the foliage in the corresponding check plats. In some of the expts. the S content was greater in the foliage that had received the higher concn. Considerable difference existed in the S content of the foliage of the checks: one set of checks = 0.34 to 0.52%; another set = 0.15 to 0.22%. These data confirm the opinion that the detn. of the S content of vegetation is not alone sufficient to det. the extent of the damage that the vegetation may have endured by SO_2 , for great differences are found in the S content of normal uninjured vegetation.

In reference to the claim that whenever crops of hay have been subjected to SO_2 fumigation and bleached, the S content is increased to the extent that the crops are injurious to animals feeding thereon, it is stated, that if such a condition does exist it certainly is not due to the increase of S content, for there are differences in the S content in normal unfumigated foliage as great as between bleached and normal foliage. The foliage from the plants fumigated with heavy SO_2 fumes had no greater S content than did the check, indicating that no SO_2 vapor was absorbed and that no fume was pptd. The S was present as sulfates or in other stable compds. The increase of the S content in fumigated grain (kernels) over that in check grain, although determinable, is very slight. Lab. expts. confirmed the data obtained in the field by showing that the disappearance of SO_2 from a mixt. of that gas and air held in a closed container in contact with vegetation is very rapid. Lab. expts. confirmed the field expts. in showing that the injury produced by SO_2 vapor, or dry SO_2 fume, is comparatively slight, if any takes place at all. Only when the SO_2 unites with H_2O to form acid particles does any injury result. Injury then can take place only when these acid particles are brought into contact with the leaves and are pptd. there. In this case the injury is confined solely to those spots where the acid particles are pptd., and is one of corrosion or desiccation at those spots, not of bleaching. Cf. Tatlock and Thomson, *C. A.* 8, 2559; cf. also *C. A.* 10, 446.

F. W. SMITH.

Components of the corn germ. E. WINTERSTEIN AND F. WÜNSCHE. Zurich. *Z. physiol. Chem.* 95, 310-36(1915).—16.48 kg. material gave 8 kg. Et_2O ext., 2.08 kg. alc. ext., and 6.76 kg. fat-free material. The corn germ contained 96.22% dry substance, 53.44 and 54.2% (2 samples) fats, containing 2.11% lecithin (1.14% of the original material). The alc. ext. contained 0.54% lecithin. The ether ext. contained 1.81% unsaponifiable matter. The ash content was 1.37%. The material after extrn. with Et_2O and alc., contained 4.47% total N (in terms of dry substance) and 4.26% protein N. The material after extrn. with Et_2O contained 3.93% protein N, 0.32% basic N and 0.46% other N. The germ substance contained 7.93% H_2O -sol. material, but no sol. carbohydrates. A pentose content of 0.13% was found, which was increased to 0.85% after autolysis. The unsaponifiable matter was sitosterin. The crude fat contained 79.55% higher fatty acids, and 2.90% lower acids, of which 0.08% was butyric and 0.24% acetic acids. The alc. ext. of the fat-free material contained 0.66% of lecithin, containing 2.87% P, and 3.91% N, which gave on hydrolysis both choline and colamine. The yield of inositol-phosphoric acid was 0.25%; that of H_2O -sol. proteins not coagulated by heat was 0.08%; of globulins, 0.02%; of alkali-sol. proteins, 4.8%. Upon hydrolysis the alkali-sol. protein yielded alanine, proline, leucine and phenylalanine, besides an acid, isolated as the copper salt, $\text{C}_4\text{H}_5\text{NO}_4\text{Cu} \cdot 2.7\text{H}_2\text{O}$ (dried over H_2SO_4), decomps. 230° ; in moist air the salt contains 4.5 mols. H_2O , of which 3.34 mols. are lost over H_2SO_4 *in vacuo* after 20 min., and 3.63 after 1 hr. Dried at 140° it contains 0.5 mol. H_2O , which is lost at 150° . The basic fraction contained humin N 0.59, NH_3 0.62, histidine 3.49, arginine 4.92, lysine 3.39, amino acid N 4.99%. The embryo does not contain protease. The aq. ext. of the autolysis contained 2.29% sugar (as glucose), 0.77% polysaccharides (as glucose), but no glucoside; the pentose content was 0.85%. The amt. of organic bases present is small. A base, $\text{C}_{17}\text{H}_{23}\text{N}_3\text{O}_4 \cdot 2.5\text{H}_2\text{O}$, was isolated as the sulfate, which was decompd. at 145° , and contained 33% of NH_3 -N. It may be a purine deriv. with 2 NH_2 groups.

S. AMBERG.

Studies on growth. II. On the probable nature of the substance promoting growth in young animals. CASIMIR FUNK AND ARCHIBALD B. MACALLUM. *J. Biol. Chem.* 23, 413-21 (1915).—It was not found possible to maintain growth in young rats on a diet of casein, starch, sugar, agar, salts and butter. After a few weeks the rats declined and died. The addition of brewer's yeast to this mixt. made it a complete diet and growth proceeded at a normal rate in the rats to which it was fed. I. G.

The resumption of growth after long-continued failure to grow. THOMAS B. OSBORNE AND LAFAYETTE B. MENDEL. New Haven. *J. Biol. Chem.* 23, 439-54 (1915).—The growth impulse, or capacity to grow, can be retained and exercised at periods far beyond the age at which growth ordinarily ceases. In the case of albino rats in which increment of body-wt. ordinarily ceases before the age of 300 days, resumption and completion of growth were readily obtained at an age of more than 550 days. The satisfactory resumption of growth can be attained not only after stunting by underfeeding, but also after the cessation of growth which results when the diet is low in protein or contains "incomplete" proteins. The rate at which growth is resumed is normal or even greater than normal for animals of that size. The size or age at which the stunting is effected does not alter the capacity to resume growth. Such stunting does not necessarily cause the loss of the procreative functions.

I. GREENWALD.

The preparation of protein-free milk. H. H. MITCHELL AND R. A. NELSON. Univ. Illinois. *J. Biol. Chem.* 23, 459-67 (1915).—Mice could not be maintained on diets of purified foodstuffs and the salt mixt. of McCollum and Davis (C. A. 8, 3673). The difference may be due to the fact that rats of McC. and D. were allowed to eat pine shavings, whereas the mice of M. and N. were kept in paper excelsior. The difference in the species may also account for the difference in the results obtained. Expts. in which the "protein-free milk" of Osborne and Mendel was used were very successful but, as about 0.5 of the N of this material is present as protein (cf. C. A. 7, 635), other methods of preparing "protein-free milk" were sought. CCl_3COOH was useful. Two portions of 10 g. of skim-milk powder were dissolved in 150 cc. H_2O and 12 cc. 50% CCl_3COOH were added. The mixt. was filtered and the ppt. washed. The filtrates were boiled 0.5 and 1 hr., respectively, filtered again and evapd. to dryness. All the acid had then been removed and the products contained, respectively, 0.401 and 0.420% N and 7.5 and 5.0% ash. The latter product did not give the biuret, Adamkiewicz or Millon reactions, nor a ppt. with picric acid or $\text{H}_4\text{Fe}(\text{CN})_6$, and only a slight ppt. with tannic acid. Phosphotungstic acid produced a rather heavy ppt. A few expts. indicated that it was as effective in maintenance as the "protein-free milk" of O. and M.

Gastrointestinal studies. II. Studies on the relative digestibility and utilization by the human body of lard and hydrogenated vegetable oil. C. A. SMITH, RAYMOND J. MILLER AND PHILIP B. HAWK. Jefferson Med. Coll. *J. Biol. Chem.* 23, 505-11 (1915).—A hydrogenated cottonseed oil was as satisfactorily digested and utilized by normal men as was lard.

I. GREENWALD.

ABNORMAL.

Prolonged and accurately timed intravenous injections of sugar. Preliminary report. R. T. WOODYATT, et al. Chicago. *J. Am. Med. Assoc.* 65, 2067-70 (1915).

—The rate of utilization of glucose in the body is detd. by finding the greatest rate at which glucose can be steadily injected into a vein without causing glucosuria. Tolerance is measured in g. of glucose per kg. of body wt. per unit of time, a result impossible to attain when administered by mouth or by a single intravenous injection, the latter representing a very high rate of injection for a very short time. The app. used is described. By its use one can pump any liquid from water to 80% glucose sirup at a rate of from 10 cc. to 5 l. per hr. It was found that a normal rabbit, dog, or man could utilize between 0.8 and 0.9 g. of *d*-glucose per kg. of body wt. per hr. without glucosuria or diuresis for an indefinite time. The authors state as "an accomplished fact" that a man weighing 70 kg., when resting quietly in bed, may receive and utilize 63 g. of glucose by vein per hr. without glucosuria, thus showing the feasibility of intravenous nutrition by glucose, and suggesting expts. with amino acids and polypeptides. It is shown that the liver is not a barrier through its "glycogenic function" to prevent sugar which is absorbed from the bowel from being lost in the urine. The belief that any large amt. of glucose, given by vein, always causes glucosuria and diuresis is an error based on clumsy methods of study. Tolerance figures are given for certain diseases. The tolerance limit for levulose was found to be 0.15 g. per kg. and hr., or one-sixth that of glucose; for galactose 0.1 g., and for lactose it approaches 0. If glucose is given by vein faster than 0.9 g. per kg. and hr., glucosuria results, then usually a little later diuresis. If the given rate of injection causes glucosuria at all, it begins to do so within 30 min. As the rates of glucose injection are increased above tolerance, the rates of overflow in the urine also increase according to mathematical laws, the glucosuria becoming constant at some level characteristic for the rate of injection. It may require several hrs. for this level to be established. If 1.7 g., or double the tolerant figure is given, the glucosuria, when constancy is attained, is about 0.17 g. per kg. and hr., which confirms the older view that increasing the concn. of food in the tissues increases the rate of utilization of glucose. An injection of 5.4 g. per kg. and hr. causes a tremendous diuresis; a 10 kg. dog passed 2800 cc. urine in 8 hrs. In giving intravenous injections of glucose too great dehydration (thirst), also too great mechanical work for the heart by too much water must be avoided. These results can both be obtained by knowing the wt. of glucose which enters the body per hr. and what vol. of water is moved by such a rate of sugar injection. Extensive clinical applications are suggested.

L. W. RIGGS.

Carbohydrate utilization in diabetes. Based on studies of the respiration, urine and blood. ELLIOTT P. JOSLIN. Nutrition Lab., Carnegie Inst. *Arch. Intern. Med.* 16, 693-732(1915).—The errors due to inaccurate methods of calcg. the carbohydrate in the diet, collection of the urine, etc., are pointed out. Attention is also called to the errors that may be due to retention of H_2O (and of glucose), retention of the N of protein after the glucose derived therefrom has been excreted, etc. From a study of the respiratory exchange and of the urinary excretion of a number of patients in which these sources of error were guarded against, J. concludes that even the severest diabetic retains some power of oxidizing glucose and that this power can be increased by suitable measures, particularly by the Allen treatment (*J. Am. Med. Assoc.*, 63, 939(1914); *Boston Med. Surg. J.* 175, 241(1915)). The diminution in the excretion of acetone and β -hydroxybutyric acid and the increase in respiratory quotient of the fasting diabetic may be due to the ability of the pateint to burn stored carbohydrate, to the oxidation of retained β -hydroxybutyric and acetoacetic acids or simply to the diminution in metabolism, which lessens the amt. of material from which these acids can be formed.

I. GREENWALD.

The carbohydrate metabolism in hyperthyroidism as determined by examination of blood and urine. H. R. GREYELIN. Presbyterian Hosp., New York. *Arch. Intern.*

Med. 16, 975-88(1915).—In moderately severe types of hyperthyroidism, hyperglucemia occurred in about 90% of the cases examd. In milder cases, normal values for blood sugar were usually found. Glucosuria, particularly after the administration of 100 g. glucose, was frequent. After administration of glucose, mild cases showed hyperglucemia, but not glucosuria. The return to normal blood-sugar values is the more delayed the greater the severity of the disease. Administration of thyroid to patients with myxedema (normal blood sugar) induced hyperglucemia. The findings are considered to be of considerable diagnostic significance. I. GREENWALD.

The chlorides in diabetes after pancreatectomy. JAMES ELAZER LEBENSOHN. Univ. Chicago. *J. Biol. Chem.* 23, 513-20(1915).—After pancreatectomy in dogs there was no change in either the absorption or excretion of NaCl. I. GREENWALD.

Metabolism in pellagra. V. C. MYERS AND M. S. FINE. New York. *Am. J. Med. Sci.* 114, 705(1913).—The general procedure in the 14 cases studied was to exam. the gastric contents for acidity and peptic activity before and after the 7-10 day metabolism period. A lacto-vegetation diet that was practically purine-free was employed; it consisted of 91 g. protein, 71 g. fat, and 460 g. carbohydrate, yielding approx. 2800 cal. Tables are given showing: (1) The comparison of the figures from gastric analysis with those of the detns. of indican and alkyl sulfates in the urine, and with those of the detns. of indole and skatole in the feces. (2) Av. daily compn. of the urine including N and S partitions and inorg. constituents. (3) Av. daily intake of food with N balance. (4) Av. daily compn. of feces. (5) Analyses of daily urines and daily N balances. The ability of these patients to utilize various foodstuffs appears to be about normal. Low creatinine and small creatine excretions were observed. An acidity was present in 8 of the 14 cases, a condition generally associated with entire absence of pepsin, or pepsin present in minute amts. Indicanuria was marked and was excessive in cases with gastric inefficiency. Though the alkyl sulfate hardly parallels the indoxyl potassium sulfate, the amts. eliminated are much higher where an acidity exists, and they hold a higher ratio to the inorg. sulfates. The feces contained abnormal amts. of indole and skatole, especially the latter. These findings point to some unusual bacterial conditions in the intestine. About 25 references to literature are given. L. W. RIGGS.

Intestinal digestion in man after excision of a large part of the lower intestine. N. A. GUREVICH. *Russ. Vrach* 14, No. 38(1915); *J. Am. Med. Assoc.* 65, 2128.—This study was made 7 months after the removal of 159 cm. of the ileum. Carbohydrates were normally assimilated; only 52% of the N was assimilated and fats were but partially digested. The patient was gaining in wt. in spite of a persistent diarrhea. L. W. RIGGS.

F. PHYSIOLOGY.

ANDREW HUNTER.

Diuresis and milk flow. H. STERNBOCK. Agr. Exp. Sta., Univ. Wisconsin. *J. Agr. Research* 5, 561-8(1915).—Expts. on goats lead to the following conclusions: Urea administered in a diuretic dose is able to decrease temporarily the flow of milk. Upon repeated administration the increased intake of H₂O which follows the impoverishment of the tissues with respect to H₂O balances the draft imposed by the diuretic, and the milk secretion comes back to normal. NaCl with its diuretic as well as laxative effect is unable to depress milk secretion under normal conditions, as it simultaneously calls forth an excessive thirst, which increases the H₂O intake. With the decreased flow of milk caused by a diuretic the % of solids is increased. Fat here is the principal variable. The mammary gland shows no tendency to absorb and subsequently to excrete additional urea absorbed by the circulation. It is difficult to interpret the results

sometimes obtained with alfalfa hay as due to diuresis alone if urea diuresis can be taken as a type.

W. H. FRY.

Composition of human milk in Australia. I. H. S. H. WARDLAW. *J. Proc. Roy. Soc. N. S. Wales* 49, 169-98(1915).—Analyses of human milk drawn from 103 women 2 to 11 days after delivery are tabulated. By an examn. of the relative frequencies of occurrence of the various percentages of the constituents found in the samples analyzed, W. has deduced the "most probable value" for each constituent. The percentage of fat varies quite evenly from 1.2 to 4.5; that is, no large number of women produced milk in which the fat percentages showed a tendency to group themselves about any particular value. The av. percentage of fat for the entire series was 3.14. Over 50% of the results for protein were between 1.6 and 2.2, the most probable value being 1.9%. For solids not fat and not protein, 60% of the results were between 6.7 and 8.7, giving a most probable value of 7.6%. The grouping of the percentages was still more pronounced with the total solids and solids not fat, the most probable values being 12.8 and 9.8%, resp. The av. percentage of fat increased from 2.84 to 4.13 during the first 11 days of nursing, while the av. percentage of protein decreased from 3.30 to 1.69 during the same period. The age of the woman, number of pregnancies, vol. of sample (the breast being completely emptied), the time since the last withdrawal of milk, and the breast from which the sample was taken appeared to have no distinct effect on the compn. of the milk examd. The total protein in the first 53 samples was detd. by the method of Sikes (1906). In the remaining samples this method was modified by using an aliquot part of the aq. layer of the liquids obtained in the estn. of fat by the Röse-Gottlieb method. This procedure has the advantage of estg. both fat and protein in the same sample, also the protein estn. is made in a liquid from which the fat is completely removed.

L. W. RIGGS.

Colloidal sodium urate in urine. BECHHOLD. *Pharmazentisches J.* 54, 264(1915); *J. pharm. chim.* 12, 230(1915).—B. proves the presence of colloidal Na urate in urine, and det. its amt. by means of the ultrafilter to be 25% of colloidal salt referred to total urates. Uric acid, if in normal amt., is partly decompd. by uric acid ferments, and partly eliminated through the kidneys. If it is in excess, calculi are formed. As long as they are in cryst. state, they may dissolve and pass the membrane of the malpighian bodies, but will not do so when they are in the colloidal state.

S. WALDBOTT.

Acetone content of milk. N. O. ENOFLDT. Stockholm. *Z. physiol. Chem.* 95, 337-50(1915); cf. *C. A.* 9, 2100, 2548.—The proteins of the milk were pptd. by tannic acid (100 cc. milk, 240 cc. distd. H₂O and 40 cc. 10% tannic acid) and the filtered soln. distd. 15 min. to remove the acetone. This was detd. by the usual method of analysis. The acetone content of cow milk varies from 1.45 to 2.42 mg. per l. The total daily amt. varies from 6.81 to 23.11 mg. Colostral milk does not differ from normal milk in its acetone content. Mare's milk contains 0.48-0.97 mg. acetone per l., sheep 0.48-0.68 mg., goat 0.97-1.45 mg., human milk 0.48-1.16 mg.

The relation of salivary to gastric digestion. LESLIE A. I. MAXWELL. Univ. Melbourne. *Biochem. J.* 9, 323-9(1915).—Colloidal starch adsorbs pepsin, thereby hindering its activity. One of the important functions of the ptyalin of the saliva is to hydrolyze the starch to non-colloidal forms.

B. HOROWITZ.

G. PATHOLOGY.

H. GIDEON WELLS.

Natural hemolysins in normal horse serum. FRED BOERNER. Philadelphia. *J. Infect. Diseases* 17, 497-9 (1915).—Because of its relation to the complement fixation test for glanders in horses, B. detd. the natural hemolysins in normal horse serum. Of 200 sera examd. for antishoop hemolysins, 1.5% were found capable of producing complete destruction of 1 cc. of a 25% suspension of these cells in the amt. of 0.4 cc. Natural hemolysins for the cells of the guinea pig, hog, goat, cat, white mouse, rabbit, chicken and man were not found. Horse serum possesses the property of dissolving the red cells of the dog without the aid of complement. J. H. L.

The effect of anaphylactic shock on the cellular reaction of the peritoneum of the guinea pig. FRANCES M. RACKEMANN. New York. *J. Infect. Diseases* 17, 542-53 (1915).—Different counts were first made of the cells in the peritoneal cavity of 22 normal guinea pigs of various weights. The cells found were large and small mononuclears, polymorphonuclears, and eosinophiles. The proportion of the different cells varied considerably in different guinea pigs and no normal could be established. Old guinea pigs tend to show a smaller proportion of small mononuclear cells than do young animals. The peritoneal fluid of guinea pigs sensitized to horse serum contained a higher % of eosinophiles than is found in the normal animal. The reaction of the peritoneum in normal guinea pigs to normal NaCl soln., H₂O, histamine, turpentine, and horse serum is qualitatively the same in each case, and consists in the rapid disappearance of the mononuclear cells and the accumulation within 3 hrs. of polymorphonuclear leucocytes in overwhelming proportions. The peritoneum of the guinea pig sensitized to horse serum reacts to an injection of horse serum differently from the normal inasmuch as the appearance of the polymorphonuclear leucocytes is much delayed. JULIAN H. LEWIS.

The part played by the acid of the gastric juice in the pathological processes of gastric ulcer. CHAS. BOLTON. Univ. Lond. *J. Path. Bact.* 20, 133-58 (1915).—The gastric juice is concerned not only in the initiation of a gastric ulcer, but also in its tendency to spread and to become chronic. It is thus responsible for the anatomical peculiarities which distinguish this ulcer from ulcers in other parts of the body. The gastric juice owes its destructive power primarily to the HCl contained in it, and the damage done to the wall of the stomach varies in proportion to the strength of the acid present. Although the HCl is usually only a factor in the initiation of an ulcer, some damage being inflicted on the gastric cells by other means, it is occasionally, when above 0.39% and combined with motor insufficiency, the actual cause of the ulcer. A gastric ulcer is more likely to spread when the gastric juice is hyperacid than when of normal acidity. The gastric juice is able to attack the connective tissue base of an ulcer by virtue of the HCl contained in it and when hyperacid to produce varying degrees of delay in the healing of the ulcer. This effect is added to when there is retention of the food in the stomach or hypersecretion of the gastric juice. This may explain the condition of delayed healing of acute gastric ulcer in man. It is probable that in human pathology a complete arrest in healing and a resulting chronic ulcer may be brought about, since the exptl. methods available for producing hyperacidity are not so effective as the conditions present in man. Since a gastric ulcer heals with difficulty in proportion to its chronicity the more chronic ulcers may be kept open by normal gastric juice. The exptl. gastric ulcer is delayed in healing by the necrotic condition of its base caused by the HCl, and it is the fibrotic base covered with necrotic tissue which prevents the healing of a human ulcer. Reducing the acidity of the gastric contents will heal a human ulcer. Hyperacidity is concerned with each of the pathological processes of a gastric ulcer. The importance of the part which the acid

plays is not always the same, since there are many different types of ulcer of the stomach brought about by an equal number of different causes. B. bases his conclusions on a considerable amt. of exptl. work with monkeys. A bibliography and a number of plates are appended.

JOHN T. MYERS.

The biochemistry of immunity reactions. CARL H. BROWNING. *Blan-Sutton Institute of Pathol., Middlesex Hosp. Brit. Med. J.* 1, 239-43(1915).—A discussion of the biochemistry of antigens, complement fixation, cytolysis, and the Abderhalden reaction.

M. RINGER.

Immunological studies in pneumonia. RICHARD WEIL AND JOHN C. TORREY. New York. *J. Exp. Med.* 23, 1-10(1916).—The serum derived from human cases of pneumonia was used to sensitize guinea pigs passively. An autolysate of a pneumococcus culture was employed as antigen. By means of Dale's method it was shown with considerable regularity that the blood contains sensitizing antibodies during the course of pneumonia, but none after the crisis.

C. J. WEST.

An experimental study of the effect of cholecystogastrostomy on gastric acidity. ERNEST G. GREY. Boston. *J. Exp. Med.* 23, 15-24(1916).—By means of a cholecystogastrostomy with ligation and division of the common bile duct, the bile was diverted from the duodenum into the stomach. With a diet of meat and water, bile, when present in the stomach throughout the course of digestion, had no appreciable effect on the acidity of the gastric contents.

C. J. WEST.

Atheroma and other lesions produced in rabbits by cholesterol feeding. C. H. BAILEY. Leland Stanford Jr. Univ. *J. Exp. Med.* 23, 69-85(1916).—The feeding of egg yolk or pure cholesterol produces an abundant deposit of anisotropic fat in various organs. From this deposit, in certain organs, characteristic lesions secondarily result.

C. J. WEST.

Intestinal obstruction. V. Proteose intoxication. G. H. WHIPPLE, F. H. RODENBAUGH AND A. R. KILGORE. Univ. of Cal. Med. School. *J. Exp. Med.* 23, 123-35(1916).—Exptl. evidence points to a primary proteose as the essential poison concerned in the intoxication from closed intestinal loops and intestinal obstruction (cf. *C. A.* 9, 2669). Proteose intoxication in dogs gives a picture identical with that described after poisoning with intestinal loop fluid. Proteoses escaping from the blood are excreted in the urine. The toxic proteose concerned in intestinal obstruction has not yet been isolated in the urine but may be excreted by the kidneys.

C. J. W.

Icterus. A rapid change of hemoglobin to bile pigment in the pleural and peritoneal cavities. C. W. HOOPER AND G. H. WHIPPLE. Univ. of Cal. Med. School. *J. Exp. Med.* 23, 137-47(1916).—Hemoglobin can be changed to bile pigment within the pleural and peritoneal cavities. This transformation can usually be demonstrated after 8 hrs. The amt. of pigment formed can in many cases be estimated quant. after 24 hrs. It is probable that endothelium as well as mesothelium can transform hemoglobin into bile pigment.

ALFRED N. RICHARDS.

Reciprocal action of sodium, potassium and calcium ions on frog heart. TAKUZO SAKAI. *Z. Biol.* 64, 505-48(1914); *J. Chem. Soc.* 108, I, 477; cf. *C. A.* 9, 752, 3594. —Increasing the K content of an isotonic soln. perfusing the isolated ventricle of a frog heart results in a decreased rate of beating, lowering of the height of contraction, and inhibition of the "extra systoles." Increasing the proportion of Ca in the perfusion fluid produces exactly the reverse effects. NaCl exerts a similar action to that of KCl, except for lower concns. Reducing the concn. of Na salt below the normal also reduces the height of contraction and the frequency of ventricular beat, and

eventually brings the ventricle to rest. The reciprocal action of Ca and of Na and K salts does not depend wholly on the ratio of their concns., but also on the abs. quantities of the substances present in the perfusion fluid. The sinus differs markedly from the ventricle in its response to changes in the compn. of the perfusion fluid. Increasing the Ca content usually slightly lowers the rate of beat, while other similar variations in the Na and K content of the perfusion fluid do not appear to have any distinct effect.

E. J. C.

A theory of internal disinfection with nascent formaldehyde. WILLIAM N. BERG. *Proc. Soc. Exp. Biol. and Med.* 12, 145-7(1915).—After administration of large doses of hexamethylenetetramine (urotropine) to cows by mouth, this substance appeared in the milk unchanged, *i. e.*, none was decomposed into CH_2O and NH_3 as stated by Klein. When, in addition to the administration of the hexamethylene-tetramine by mouth, the cows received $N/6$ HCl intravenously, small amts. of CH_2O were found in the milk, but these quantities were too small to be effective in disinfection.

WILLIAM N. BERG.

Collected abstracts from the field of pharmacology, July to Sept., 1915. CARL BACHEM. *Bonn. Zentr. inn. Med.* 36, 789-99(1915).—A good bibliography is given.

JOHN T. MYERS.

Terpacid. R. TOPP. *Zentr. inn. Med.* 36, 357-60(1915).—An isomer of camphor, $\text{C}_{15}\text{H}_{26}\text{O}$, is described and several cases in which it was successfully used as a skin disinfectant are given. It does not produce the objectionable effects that camphor does. It tends to reduce blood pressure and heart action.

JOHN T. MYERS.

A preliminary note on chronic poisoning by emetine. H. H. DALE. *Läster Inst. Brit. Med. J.* 2, 895(1915).—Emetine in daily doses of 5 or 10 mg. may be given hypodermically during a limited period to rabbits and cats weighing from 2.5 to 3.5 kg. without apparent harm. When the period is extended, symptoms of intoxication always appear. In rabbits diarrhea and emaciation are the usual effects, while cats develop lethargy and somnolence terminating in coma. The dose employed in D.'s expts. corresponded to one slightly greater than that usually used in human treatment.

A. H. RAHE.

Mercury elimination in bichloride poisoning. KARL M. VOGEL AND O. IVAN LEE. *Med. Record* 89, 58-60(1916); cf. *C. A.* 8, 1596.—A study of Hg elimination based on the work of Lambert and Patterson (*Arch. Intern. Med.* 16, 865(1915)) and on that of Lieb and Goodwin (*C. A.* 9, 2673).

A. H. RAHE.

Soluble radium salts in organic nervous diseases. ALFRED GORDON. Philadelphia. *N. Y. Med. J.* 102, 1225-7(1915).—When sol. Ra salts are injected into the spinal canal of dogs showing flaccid paralysis of the hind quarters, owing to compression of the cord, if the injection is made above the compressed area, muscle spasticity in the forelegs, and respiratory embarrassment, are induced. If the injection is made below the compressed area spasticity occurs in the paralyzed hind legs. Injection into the uncompressed cord induces rigidity in the hind legs. The dose used was 25 micrograms in 2 cc. The compn. of the Ra compd. used is not stated.

A. H. RAHE.

The metabolic influence of the chlorides on certain dermatoses. M. I. D. AND S. A. STEINBERG. Louisville. *J. Cutan. Dis.* 33, 367-72, 467. Discussion of the theories advanced to explain the retention of chloride in nephritis, and of the value of chlorides in treatment of skin eczemas.

Trichloroacetic acid and its uses in dermatology. Philadelphia. *J. Cutan. Dis.* 33, 691-5.—When applied acid forms a dry eschar and thus prevents inva-

agents and ulceration. It is employed successfully in degenerative seborrhoea, pigmentations papillomata and naevi, xanthoma palpebrarum, etc. The method of application in some of these is described. M. RINGER.

Pharmacological investigation of the respiratory center. HERMANN WIELAND. Strassburg. *Arch. exp. Path. Pharm.* 79, 95-117(1915).—A method is given (see original for details) for the accurate detn. of the CO_2 of the alveolar air and the corresponding CO_2 tension of the blood in birds. The threshold value for CO_2 in normal pigeons is under 2%. The sensitiveness of the respiratory center is diminished by urethan and chloral. It is apparently directly stimulated by camphor, coriamyrtin and lobeline, and by CO_2 . C. J. WEST.

Croton resin. R. BOEHM. Univ. Leipzig. *Arch. exp. Path. Pharm.* 79, 138-53 (1915).—Croton oil is light yellow to brownish red in color and has $[\alpha]_D$ from $5^\circ 36'$ to $8^\circ 12'$. Solvents have no influence upon the rotation, which is due to the resin. The oil may be freed of resin by extn. with MeOH in the cold, and is then nearly neutral and optically inactive. The resin is freed from fatty acids by extn. of the petroleum ether-alc. soln. with 10% K_2CO_3 soln., and then adding finely pulverized $\text{Ba}(\text{OH})_2$ to an alc. soln. of the residue. The residue from this extn., completely freed of alc., is then extd. with petroleum ether, which exts. the neutral fat. The resin is a nearly colorless or light yellow powder, m. $80-90^\circ$, and behaves as a colloid. It is sol. in all organic solvents except petroleum ether. The I no. is 76.98; $[\alpha]_D$ varies from 49.96° to 63.23° ; it analyzes for $\text{C}_{26}\text{H}_{44}\text{O}_8$. Completely hydrolyzed by 30% aq. KOH for 12 hrs., it yields fatty acids and amorphous resinous substances. C. J. WEST.

The cause of the increased action of adrenaline upon the blood pressure of rabbits produced by pituitary extracts. HELENE BÖRNER. Univ. Freiburg. *Arch. exp. Path. Pharm.* 79, 218-49(1915).—The pituitary exts. act as a heart poison in rabbits. This causes a greater concn. of adrenaline in the blood and thus produces an increased action upon the blood pressure. C. J. WEST.

The change of the pulse produced by vasoconstrictor agents. K. HÜTHLE. Univ. Breslau. *Arch. ges. Physiol.* 162, 338-58(1915).—A study of the effect of adrenaline, pituitrin, digitalis, and KCl upon the pulse. C. J. WEST.

I. ZOÖLOGY.

R. A. GORTNER.

Action of santonin and its derivatives upon the musculature of worms, and remarks on the action of Oleum chenopodii. PAUL TRENDLENBURG. Univ. Freiburg. *Arch. exp. Path. Pharm.* 79, 190-217(1915). C. J. WEST.

Aplysia poison. FERDINAND FLURY. Univ. Würzburg. *Arch. exp. Path. Pharm.* 79, 250-63(1915).—The milk-white secretion of *Aplysia delipans* has the compn.: H_2O and volatile matter, 94.9%; dry substance, 5.1%; Et_2O -sol., 0.29%; org. substance, 1.4%; mineral matter, 3.7%; NaCl, 2.47%. The violet secretion has the compn.: H_2O and volatile matter, 94.8; dry matter, 5.2; org. substance, 1.6; mineral matter, 3.60; NaCl, 2.92%. The milk-white secretion contains a small amt. of a base. The principal component is a N-free oil, volatile with steam, which seems to be a terpene. The poisonous substance belongs to the nerve and muscle poisons and paralyzes the heart muscle of frogs. The violet secretion is not poisonous. C. J. WEST.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Report on preservatives. A. F. SEEKER. *J. Assoc. Official Agr. Chem.* 1, 210-8 (1913).—A brief review of the literature relating to the detn. of HCO_2H is given and as

a result of a consideration of the proposed methods the Fincke procedure (C. A. 7, 2258) was selected for trial. The accuracy of the method as applied to fruit juices and sirups was confirmed by S. and by 7 other analysts working upon samples of known HCO_2H content. By substituting a suspension of BaCO_3 for the CaCO_3 ordinarily used by Fincke in the absorption of HCO_2H in the distillates, it was found that interference of SO_2 in the material under examn. is eliminated. A. F. SEEKER.

The determination of lead in phosphate and alum baking powders. A. F. SEEKER AND H. D. CLAYTON. *J. Assoc. Official Agr. Chem.* 1, 264-6(1915).—The method depends upon the pptn. of PbS from a soln. of the baking powder containing a large excess of ammonium citrate which prevents the pptn. of phosphates and at the same time allows a quant. sepn. of the PbS ; the latter is converted into PbSO_4 and then into PbCrO_4 , which is weighed. Heat a mixt. of 25 g. baking powder, 25 cc. water and 25 cc. of concd. HCl on a steam bath till the starch is hydrolyzed and practically all the solid material has gone into soln. Add 25 g. of Pb -free citric acid or its equiv. of ammonium citrate, dil. to 500 cc., cool, and render slightly alk. to litmus with NH_4OH , keeping the mixt. cool during this operation. Acidify with a little dil. HCl , sat. with H_2S , allow the sulfides to sep., filter, wash with H_2S water, dissolve the sulfides by the successive addition through the filter of small amts. of hot dil. HCl and dil. HNO_3 , wash with hot water, add 2 cc. of concd. H_2SO_4 to the filtrate and washings, and evap. to white fumes on a hot plate. Cool, add 10 cc. of water, warm to dissolve $\text{Fe}_2(\text{SO}_4)_3$, cool, add 20 cc. of EtOH , allow the mixt. to stand overnight, sep. the PbSO_4 on a filter, wash with EtOH , dissolve in 50% $\text{NH}_4\text{C}_2\text{H}_3\text{O}_2$ made slightly alk. with NH_4OH , wash the filter with a little water, acidify the filtrate and washings with AcOH , and ppt. the Pb as PbCrO_4 . Filter upon a small tared Gooch, wash, dry and weigh as PbCrO_4 . A. F. SEEKER.

Aluminium alloys and their use for canteens and cooking utensils. J. BOGS AND H. WEYLAND. *Z. Nahr.-Genussm.* 30, 300-5(1915).—Al alloys containing 95.81 to 97.49% of Al and 3 or more of the following elements: Cu, Fe, Ni, Mg, Ca and Si, in various proportions, were moistened with distd. water and ordinary tap water and placed in a moist chamber. After 2 days the alloys, especially in cases where tap water was used, were coated with a 0.5 cm. layer of hydrated oxides. In alloys containing Mg this element was found in relatively large amts. in the oxide coating whereas Cu, Ni and Fe when present in the alloys were never found in the coating which in these cases consisted of hydrated Al oxide. The corrosion of the alloys is due to electrolytic action and varies with the relative difference of potential between the various metals constituting the alloy. Thus Mg, Al, Fe, Ni and Cu are attacked in the order named. To confirm these observations a number of small vessels were constructed of pure Al foil. Half of these were filled with pure water and half with 0.6% NaCl soln. Into 2 of the vessels containing water and NaCl soln., resp., Mg turnings were placed, into 2 others short pieces of bright Fe wire, into a third set Cu strips, and a fourth set was used as a blank. The vessels were allowed to remain in a moist chamber for 24 hrs. The Al in the blank tests was not perceptibly attacked. In all the other cases vigorous action had taken place to a greater extent with the NaCl soln. than with the water. Mg had been attacked where it was used, but in the other cases only Al had been corroded. B. and W. conclude that Al alloys containing less than 98% Al are of no value for canteens or cooking utensils. Al of greater purity can easily be prepd. upon a technical scale and should be preferred. H. L. LOURIE.

Report on colors. W. E. MATHEWSON. New York. *J. Assoc. Official Agr. Chem.* 1, 470-2(1915); cf. C. A. 9, 3105.—The work in 1914 was largely an attempt to extend the methods of coal-tar color analysis to the commonly occurring natural coloring matters such as those in the juices of cherries, blackberries, raspberries, cur-

raints, grapes and huckleberries. These coloring matters, though extd. in relatively small amt. by amyl alc. from acid solns., were found to be quite readily changed by heating with dil. HCl, substances similar in color reactions but much more sol. in amyl alc. being formed. These derived colors were obtained fairly free from other substances by the following method: Treat the fruit juice with excess of neutral $\text{Pb}(\text{AcO})_2$ soln., which will throw down practically all coloring matter, wash the ppt. with water several times by centrifuging, dissolve the coloring matter by treatment with 10% HCl, and ext. the HCl soln. with amyl alc. to remove the coloring matter taken up by this solvent. Then boil the HCl soln. a few min. and again shake out with amyl alc. The new coloring matter formed by hydrolysis of the glucoside is then extd. in large proportion, and the amyl alc. soln. freed from HCl, PbCl_2 , etc., by washing with water.

L. W. RIGGS.

Permeability of Pukall filters for milk albumins. G. DIERSSELHORST AND F. REISZ. Charlottenburg. *Chem. Ztg.* 39, 901-2(1915).—Expts. using several filters with H_2O and with fresh and boiled milk showed that the modern filters are much less porous than those first manufd., and that the albumins were completely removed from milk, while the mineral salts passed through. From aq. solns. of egg albumen the removal was almost complete.

J. H. MOORE.

Hygienic milk. J. PRITZKER. Frauenfeld, Switzerland. *Schweis. Apoth. Ztg.* 53, 583-6, 593-7, 609-12, 624-8(1915).—Milk is an especially important food in Switzerland. The amt. used is highest in Lucerne, 0.92 l. per person per day. The chem. characteristics of milk are given. Thöni (*Centralbl. f. Bakt. Parasitenk. Infect.* 74, Heft 1-2(1914)) proved the presence of tubercle bacilli in 8% of Bern market milk. P. makes a strong plea, quoting Lührig (cf. *C. A.* 6, 1321) and Burri (*C. A.* 6, 260), for the keeping of filth out of milk. Its amt. has been 10 mg. per l. From unclean milkers' hands, 7000 to 25,000 germs per cc. were added to milk; when the hands were rubbed with fat, the number decreased to 200 per cc. (E. v. Freudenreich). P. shows that air of the stable contained from 338,000 to 512,000 germs per m^3 , compared with only 200 to 6500 for the air of the town of F. Pasteurization and sterilization reduce the number of bacteria, but boiling alters the chem. compn. of milk (cf. P. Rupp, *C. A.* 7, 2443). Sterilized milk is held responsible for rhachitis and scurvy in infants. Raw milk obtained and handled with due precautions, is the only proper substitute for mother's milk. S. WALDBOTT.

Digestibility of cell-walls of wood. G. HABERLANDT AND N. ZUNTZ. *Sitz. berl. preuss. Akad.* 1915, 686-708.—The analytical and microscopical results of the expts. show that the cell-walls which have only partially changed into wood, such as is the case in birch wood, are readily digestible by ruminants. A very fine grinding of the wood, originally considered necessary in order to render the contents of the cells accessible, has also been found a useful means for unlocking the cell-walls themselves.

C. A. NOWAK.

The significance of hay meal for the nourishment of animals and man. F. OETKEN. *Wiener Landw. Ztg.* 65, 338(1915).—Analyses of alfalfa and red clover are compared with those of barley, wheat, rye, rye straw and oat straw to show the relative food value of the different products. The legume hay occupies an intermediate position between the grains and straws.

C. F. MILLER.

Treating milk. BERNA MILK CO. Brit., 18,795, Aug. 18, 1914. In order to remove acidity, milk is subjected to the action of an elec. current. Al electrodes are employed and may be kept in motion during the treatment.

Coagulant for milk. M. PIORKOWSKI. Ger., 285,226, Jan. 12, 1913. The coagulant consists of the metabolic products of the yoghurt bacteria, sepd. from the

bacterial bodies. The bacteria are grown, separately, on suitable media, for several weeks, in order to obtain a large yield of the products of metabolism, and these products are sepd. from the bacterial bodies. Preferably the cultures, together or sepd. according to the respective strains, are shaken up with a small amt. of H_2O_2 , with warming; this is repeated, as often as necessary, after repeated heating, and the products are sepd. from the bacteria by centrifugalization. Also, from the cultures, obtained by continued cultivation, suspended in physiological salt soln., the products may be pptd. by means of Fe_2Cl_3 , the ppt. being warmed, shaken with physiological salt soln., filtered through a bacterial filter, and the filtrate, containing the desired products, being purified by centrifugalization. After each treatment with H_2O_2 the sediment of bacteria remaining in the centrifuge contains still sufficient antigens (*i. e.*, substances which can produce lactic acid) to justify its further use. On the contrary, the residual bacteria after the treatment with Fe_2Cl_3 are exhausted and no longer useful. The cultures may be filtered directly through bacteria filters. The clear filtrate contains, then, likewise, the products of metabolism of the bacteria; nevertheless the prepn. is less active.

Permanent fruit extracts. H. THOMS. Ger., 285,304, June 20, 1914. The exts. contain the aromatic substances and the ferments of the fruit juices unaltered. The juices, obtained in the usual manner by compression of the comminuted fruit, are dialyzed in cooled chambers to reduce the acid content, then evapd. to the desired density in vacuum app. free from metal, at a low temp. not destructive to the ferments. Upon dialysis the aromatic substances and the ferments do not pass through the membrane, but the acids do pass through in part. *E. g.*, a fruit juice obtained by the cold extn. of pineapple, and containing about 0.9% free citric acid, is allowed to flow through a system of cooled chambers, constructed like a filter press, of parchment walls, and surrounded by chambers of pure H_2O . A portion of the free acid diffuses into the chambers filled with H_2O . The acid content of the pineapple juice is in this manner reduced in a short time to 0.3-0.2%, which upon evapn. *in vacuo* no longer exerts an injurious action upon the ferments of the pineapple. The exts. are recommended for the manuf. of refreshing beverages, marmalades, etc., and find application pharmaceutically in the form of pastilles, tablets and capsules.

Continuous production of preserved potato. C. WARTH. Ger., 285,315, June 6, 1913. See Brit., 3,531 (*C. A.* 9, 2160).

Baking dough from oil seeds. F. MÜLLER. Ger., 285,332, Feb. 28, 1914. Coherent masses could not be obtained from almonds and other oil-containing seeds, with the use of large amts. of flour, say 15-20%, since with a small amt. of H_2O the mass becomes too solid and hard, and with a larger amt. of H_2O the mass spoils readily. A coherent easily worked mass, with a large amt. of flour, can be obtained by first working up the flour with a little H_2O or milk to a stiff dough, rolling this out to thin sheets, and baking them at a low oven temp. The baked product is rubbed up to a fine powder, and 15-20% of this powder is added to the mass prepd. from the oil-containing seeds and sugar. The mass, and the cakes prepared therefrom, are said to be very palatable.

Apparatus for the culture of yeast used for the determination of various sugars by fermentation (TRAMBICS) I.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

History of the manufacture of mineral water. OTTO VOGEL. Düsseldorf. *Chem. Ztg.* 39, 928(1915).—Quotation from an article published in 1803. J. H. MOORE.

Determination of specific electric conductivity in examination of potable waters. M. FORNAINI. Rome. *Ann. chim. applicata* 4, 150-82(1915).—Detns. were made on a large number of waters. The formula used was that of Kohlrausch, $0.75K \cdot 10^6 =$ quantity of salts in mg. contained in 1 l. of water, K being the sp. elec. cond. F. discusses the influence of temp., and, on the basis of the formula $K_{18} = K_t / (1 + 0.023 \cdot [t - 18]) = Km$, gives a table of values of m_t for temps. from 0° to 25° . He also discusses the influence of dissolved gases, of organic substances in soln., of substances in the colloidal state, of the saline compn., and of the concn. The sp. elec. cond. of the waters was compared with the dry residue by wt. at 110° . F. shows that the coeff. 0.75 in Kohlrausch's formula is too high, and that more concordant results are obtained by using the value 0.71, or by correcting the value from Kohlrausch's formula on the basis of the hardness of the H_2O ; approximations better than $\pm 5\%$ were thus found. Waters with a value of cond. $K_{18} \cdot 10^6$ below 200 give unreliable results, because at such dilns. the errors of observation first become appreciable, unless special precautions are taken that make the method impracticable. With waters where the value $K_{18} \cdot 10^6$ is above 700, anomalies become greater and more frequent, on account of the less dissociation of the salts in soln. and because of the greater complexity of the saline solns. In such cases the water should be dild. with twice-distd. H_2O or with distd. H_2O of known cond. and proper corrections made. A cond. of $K_{18} \cdot 10^6 = 700$ corresponds to a value of 500 mg. per l., considered by most hygienists as the max. tolerable limit for a good potable water. The detn. of the sp. elec. cond. gives an indication of the amt. of salts in soln., according to F., more approx. correct than values of dry residue obtained by wt., although each method has its proper place; but where rapidity is a desideratum the detn. of the sp. elec. cond. may advantageously substitute that of the dry residue by wt. In detg. small variations of compn., as in continuous hygienic supervision of an aqueduct, spring, etc., the detn. of cond. together with that of 1 saline constituent, e. g., Cl, furnishes a more refined and rigorous means than detn. of dry residue by wt. An extended bibliography of references to the literature is appended. S. LEVY.

Detection of free carbonic acid in water. L. W. WINKLER. *Z. angew. Chem.* 28, I, 376-8(1915).—To 100 cc. of a fresh sample of water add 2 drops of a 10% $CuSO_4$ soln. In the presence of free CO_2 the water will remain clear for at least 10 min. This test, however, is not adapted to soft water which should be tested preferably by adding 10 drops of a 1% soln. of alizarin in alc. A bluish red color indicates an absence of free CO_2 , while a pure yellow color indicates the presence of a large amt.

W. F. LANGELEIR.

Waters of Beaucens. F. GARRIGOU. *Compt. rend.* 161, 144-6(1915).—This water, which is valued highly on account of its therapeutic properties, contains salts of Pb, Zn, Sb, As, Sn and Cu.

W. F. LANGELEIR.

Experiment with natural water-softening zeolite. R. N. KINNIARD. *Eng. Record* 72, 794(1915).—A natural hydrous calcium aluminium silicate was used in the expts. Waters having carbonate and sulfate hardness of 300 were softened. Filtration through 2 ft. of material at a rate of 2 gal. per min. per sq. ft. gave satisfactory results. K. suggests treatment similar to rapid sand filtration. Salt for regeneration of the zeolite would be about 2.5 c. per 1000 gal.

FRANK BACHMANN.

Wooden filters prove economical for temporary exposition water supply. E. C. EATON. *Eng. Record* 72, 748-51(1915).—Water for the Panama-Pacific International Exposition was secured from several sources. The estd. daily requirements were from 1.4 to 2.5 mil. gal. The water-works system consisted of a sump and five deep wells delivering water to a filtration plant, a main pumping station, pumping water through a 12-in. steel pipe line to a height of 365 ft., a distance of 19,300 ft., a reservoir of 3 mil.

gal. capacity and a gravity pipe line to the Exposition grounds, 5,200 ft. long. The water was treated with 1 grain per gal. $\text{Al}_2(\text{SO}_4)_3$, which was applied by an automatic controlling device, settled, filtered and then treated with 3 lbs. Cl per mil. gal. The cost of operation per 1000 gal. water treated was 6.426 c. The analysis showed *B. coli* positive in 10 cc. of the raw water and a bacterial count of 100, while the treated water showed no *B. coli* and a count of about 12. FRANK BACHMANN.

Pressure chamber equalizes wash-water distribution at Miraflores filters. GEORGE C. BUNKER. *Eng. Record* 72, 787-9(1915).—The raw water is a mixt. of Chagres River and Gatun Lake water. On account of odors the raw water is aerated. An av. of 192 lbs. alum per mil. gal. is added and the water allowed to settle, after which it is filtered. The filtered water is treated with 20 lbs. CaOCl_2 per mil. gal. which eliminates the *B. coli* and reduces the bacterial count on nutrient agar to an av. of 7 per cc. The unique feature of the plant is the design of the filters, a detailed description of which is given. FRANK BACHMANN.

Cubic performance. LESLIE C. FRANK. *Eng. Record* 72, 751-2(1915).—This term is intended to designate the rate of volumetric work done by sewage and water treatment devices. It is defined as the number of unit volumes of liquid treated per unit volume of device in a unit time. FRANK BACHMANN.

Oxidation of sewage without the aid of filters. III. E. ARDERN AND W. T. LOCKETT. *J. Soc. Chem. Ind.* 34, 937-43(1915); cf. *C. A.* 8, 2207, 2766; 9, 679.—Manchester sewage was aerated in 50-gallon casks. Nitrification was not completed during each aeration. In 4 weeks enough sludge was obtained to give satisfactory results with 8 hours' aeration. Data as to amt. of sludge produced were inconclusive. Mineral precipitates were added to the sludge, but no advantage ensued; a deflocculating action was frequently observed. Expts. in gallon bottles indicated that the volume of air necessary may be as low as 6 cu. ft. per hr. per sq. ft. of tank area. The best proportion of sludge to sewage is given as 2:3 for Manchester sewage. Estimated cost of air per million gal.: minimum \$1.98, max. \$4.92, with electricity at 1 c. per kw. hr. F. W. MOHLMAN.

A new electrolytic method of sewage disposal. J. C. OLSEN. *Met. Chem. Eng.* 13, 735-9, 793-7(1915).—An efficiency test was made of an electrochemical plant recently installed at Elmhurst in New York City. The process comprizes essentially electrolytic treatment, coagulation with lime, sedimentation and sludge removal. The cell is $24\frac{1}{4} \times 3 \times 2\frac{3}{4}$ feet in size and its nominal capacity is 500,000 gal. per day. The sewage flows through the cell under pressure, the retention period being approx. one minute. The quantity of current used varies between 22.5 and 44.7 coulombs, equiv. theoretically to the liberation of 1.21 and 2.31 cc. of O per liter of sewage treated. The total active surface of the electrode plates is 64.5 sq. ft. The range of current density is from 0.6 to 0.8 amp. per sq. ft. for one set of electrodes of which there is a total area of 48.9 sq. ft., and 1.9 to 2.6 amp. per sq. ft. for the smaller plates of which there is a total active area of 15.6 sq. ft. Hydrated lime equivalent to 9.1 grains per gal. is added after electrolysis. Sedimentation of the sludge is afforded by two tanks furnishing a retention period of 4 hrs. The analytical data obtained indicate that the treatment produces a very satisfactory effluent, clear and free from unpleasant odor. Nitrate N is increased from 0.02 to 3.8 p. p. m. Organic N is reduced from 13.8 to 5.5 p. p. m. The estimated cost of operation for a 10 mil. gal. plant is \$12.72 per million gallons divided as follows: Elec. current at 2 cents per kw. hr. \$3.22, lime \$3.00, labor \$3.00, sludge disposal \$2.50, and renewals \$1.00.

Electrolytic sewage treatment. W. P. MASON, J. C. OLSEN, C. O. MAILLOUX AND P. M. TRAVIS. *Munic. J.* 39, 549, 551-4 (1915); cf. preceding abstract. L. P.

Gas lighting and hygiene. M. VON GRUBER. *J. Gasbel.* 58, 413-21, 429-34 (1915).—A report of the expts. described in *C. A.* 9, 1212, but at much greater length and with full experimental data. W. L. BADGER.

Report of the Selby Smelter Commission (HOLMES) 9. Apparatus for converting sulfur dioxide to sulfur trioxide (WELLS) 1. Disappearance of sulfur dioxide from dilute solutions with air (BARTELLS) 9.

Softening and sterilizing water. H. J. MACGRATH. *Brit.*, 18,867, Aug. 20, 1914. A cylinder containing zeolitic material for softening and sterilizing H_2O , which is supplied through a cock and perforated pipe and is discharged through a pipe, is fitted with a device for supplying a regenerating soln. and washing H_2O controlled by cocks which are connected to the water supply cock so that they cannot be opened unless the water supply cock is closed. The regenerating soln. is prepd. in a tank, which may be made of earthenware, divided by a vertical partition having perforations into 2 compartments, one of which is supplied with H_2O through a ball-cock, and the other of which contains a grid on which a solid regenerating salt, such as $NaCl$ or $K_2Mn_2O_8$, is placed. When the cocks admitting the regenerating soln. and H_2O are opened, the H_2O passes through the zeolites and is discharged. The stream of H_2O serves first to dissolve the salt and carry the soln. through the zeolites, and later to wash out the excess of the soln.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

The oxidizing power of soils. F. C. GERRETSEN. *Arch. Suikerind.* 23, 834-47 (1915).—Soils generally have the power of liberating I from solns. of KI. This I may remain free, or may oxidize org. material, or may be added to unsatd. org. substances present. Soils which had a normal oxidizing power were tested before and after sterilizing; the amt. of I liberated decreased noticeably, indicating that in case soils have an oxidizing power it is at least partly due to oxidases. The oxidizing power of a soil was quant. detd. as follows: As rapidly as possible 2 g. were weighed out, ground with 50 cc. H_2O , and rinsed into an Erlenmeyer flask, 5 cc. of 1% KI were added with 6 drops of 1:1 H_2SO_4 allowed to stand 5 min., and centrifuged. One min. generally sufficed for a clear sepn., but the liquid was filtered also as an additional precaution. I was then detd. either with 0.01 N $Na_2S_2O_3$ or, for very small amts., colorimetrically. If larger samples must be used they may be disintegrated by mixing with H_2O and drying at ordinary temps. in a vacuum. This disintegrates the finest clays and no risk is run of destroying enzymes or bacteria. Shorter standing than 5 min. after adding KI decreases the amt. of I liberated, but longer standing than 5 min. does not increase it greatly. Tests on 19 soils are reported. In 6 cases where the stand of cane was good, from 120 to 354 mg. I were liberated from 100 g. soil; in 3 cases where the stand was fair to moderately poor, 79 to 184 mg. were liberated; and in 11 cases where the stand was bad there was no I liberated in 8 cases and up to 47 mg. in the others. The amt. of gaseous O necessary to liberate the av. amt. of I would amount to 30 to 100% of the pore space in a heavy clay soil. Hence it is concluded that the poor stand of cane on strongly reducing soils is due to lack of O at the root tip. In sampling such soils the sample should not be taken from the surface layer. It should be taken in as large pieces and as quickly as possible, and put into a container which can be sealed air-tight. W. L. BADGER.

Osmosis in soils. C. J. LYNDE AND J. V. DUPRÉ. Macdonald College, Quebec. *J. Am. Soc. Agronomy* 7, 283-92(1915); cf. *C. A.* 9, 1524.—It is concluded from experimental data that water moves through clay subsoil from a weak soil soln. toward a strong one. This is ascribed to osmosis. B. E. B.

The nitrogen problem in arid soils. CHAS. B. LIPMAN. Coll. Agr. Univ. Cal. *Proc. Nat. Acad. Sci.* 1, 477-80(1915).—This problem is discussed generally and the following practical bearings are pointed out: The addition and maintenance of a good supply of org. matter by green fertilizing or by the use of barnyard manure must be practiced on all soils deficient in N and org. matter. Nitrogenous fertilizers, when employed on such soils, must be either of the low-grade org. variety such as steamed bone meal, cottonseed meal, and sewage sludge, or else $(\text{NH}_4)_2\text{SO}_4$ must be used. The overheating of the soil, excessive evapn. of moisture, and oxidation of org. matter should be prevented through the use of some kind of straw or manure mulch.

W. H. FRY.

The origin of the "niter spots" in certain western soils. ROBERT STEWART, Univ. Ill., AND WILLIAM PETERSON, Utah Agr. Coll. *Science* 43, 20-4(1916).—A general discussion.

W. H. FRY.

Some suggestions on methods for the study of nitrification. W. P. KELLEY. Univ. Cal. *Science* 43, 30-3(1916).—One % dried blood failed to undergo nitrification in those soils which had not been consistently fertilized with org. manures. When the concn. was reduced to 0.25% or less, vigorous nitrification took place. Similar results were obtained with bone meal and $(\text{NH}_4)_2\text{SO}_4$. Addition of either NH_4OH or $(\text{NH}_4)_2\text{CO}_3$ partially inhibited nitrification even in the low concn. of 5 mg. per 100 g. soil.

W. H. FRY.

The influence of nitrification upon soil fertility. WM. L. OWEN. *Sugar* 17, No. 11, 30-31(1915).—A review of the subject with tables showing the relative nitrification of $(\text{NH}_4)_2\text{SO}_4$ and various other N-carrying substances.

A. GROSS.

The soils of Kentucky. S. D. AVERRITT. Kentucky Agr. Exp. Sta., *Bull.* 193, 129-64(1915).—A general discussion of soils, plant food and fertility from a chemical, physical and biological standpoint. Analyses of a number of soils and subsoils from different areas are given.

B. E. B.

Soils of Franklin County, Ky. S. C. JONES. Kentucky Agr. Exp. Sta., *Bull.* 195, 201-35(1915).—The bulletin contains a soil survey of the county and chem. analysis of various soil types encountered. Total N was detd. by the Kjeldahl method, total P by the $\text{Mg}(\text{NO}_3)_2$ method and total K by the J. Lawrence Smith method. "Available" P, K and Ca were detd. by digesting 200 g. soil in 2 l. 0.2 N HNO_3 for 5 hrs. at room temp. Acidity was detd. by the method of Hopkins.

B. E. B.

Determination of arsenic and lead in soil. C. F. SHAW AND E. E. FREE. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 455-6(1915); cf. *C. A.* 10, 446.—Arsenic was detd. by digesting a weighed sample of the well-mixed, dried soil with H_2SO_4 for several hrs., transferring to a Marsh app., and comparing with standard mirrors. **Lead:** Digest 500 to 1000 g. of the dry soil, first with HNO_3 , then with AcOH and AcONH_4 . After each digestion, wash with H_2O by decantation and on a filter. To the filtrate from the HNO_3 digestion add $\text{K}_2\text{Cr}_2\text{O}_7$, filter, dissolve the ppt. in HNO_3 , add H_2SO_4 and sep. Pb as PbSO_4 ; dissolve the PbSO_4 ppt. in AcOH and AcONH_4 , ppt. PbS with H_2S , filter, dissolve in HNO_3 , and reppt. as PbSO_4 . Usually it is necessary to repeat twice or more the purification by successive pptn. with H_2S and H_2SO_4 . Treat the filtrate from the AcOH digestion directly with H_2S , and purify the ppt. by repptn. as sulfide and sulfate as above. Both ppts. are finally weighed (separately or together) as PbSO_4 .

F. W. SMITH.

The reaction of soil and measurements of hydrogen-ion concentration. L. J. GILLESPIE. Washington, D. C. *J. Wash. Acad. Sci.* 6, 7-16(1916).—Procedures were devised for the electrometric and colorimetric detn. of H-ion concn. in soil admixed with 2 parts of water, and 22 soils of various types and reactions were examd. by means of these procedures. The H-ion exponents so detd. were from 4.4 to 8.6. In 19 cases, 2 different indicators could be used for each colorimetric test, and in these cases there was a good agreement between the results so obtained. In all cases there was a good agreement between the electrometric and the colorimetric results. The expts. are being continued. (Author's abstract.) L. J. GILLESPIE.

A proposed rapid method for the analysis of limestone for agricultural processes. A. S. BEHRMAN. State Univ., Lexington, Ky. *J. Ind. Eng. Chem.* 8, 42-5(1916).—One g. of the rather finely crushed sample is weighed into a 200 cc. Phillips beaker. Into this is pipetted 50 cc. standard 0.5 N HCl, followed by a few drops of a 3% H_2O_2 soln. A small porcelain crucible is set loosely in the top of the beaker, and the whole placed on the water bath. After remaining at this bath temp. (86°) for 30 min. the beaker is removed from the bath and cooled. When almost or completely cooled, 5 g. of dry NH_4Cl are added and dissolved by agitation; some macerated filter paper is also introduced. 25 cc. of a standard 0.5 N NH_4OH soln. are then added slowly with shaking. The beaker is stopped with a rubber stopper, agitated well and let stand for 15 min. Filtration is now made as rapidly as possible through an ashless filter into a 350 cc. Erlenmeyer flask, and the ppt. washed thoroughly with a neutral 10% soln. of NH_4NO_3 until all the NH_3 is in the filtrate. The ppt. is ignited and weighed. The wt. thus obtained represents the insol. residue, plus the Al and ferric oxides. The filtrate and washings from the insol. residue and NH_3 ppt. are titrated with standard 0.5 N HCl, using methyl orange as an indicator. From the HCl required to put the carbonates into soln., and from the total carbonates (found by subtracting the insol. residue and ignited NH_3 ppt. from 100), can be calcd. the % of Ca and Mg carbonates present. This method may be employed where only an approximation is desired. NH_3 pptns. may be made quantitatively in the cold, in the presence of NH_4 salts, and with the aid of some macerated filter paper to facilitate coagulation. 0.5 N HCl soln. may be heated, under the proper conditions, for 30 min. or more on the water bath (86°), without loss of HCl. NH_4Cl exerts an inhibitory action upon the pptn. of $CaCO_3$ to a much greater extent than is generally ascribed to it. W. H. FRY.

Acid soils and the effect of acid phosphate and other fertilizers upon them. S. D. CONNER. *J. Ind. Eng. Chem.* 8, 35-40(1916).—Various acid constituents of soils show different degrees of reactivity with different bases, also with the same base when free or when combined with different acids. The acidity developed when acid soils or silicates are treated with neutral salt solns. is more probably due to chem. exchange of bases than to physical selective adsorption. Ignition of acid soils also destroys the acidity. Much of the harmful acidity of acid soils is due to the presence of toxic acid salts of Al and Fe. The immediate effect of the addition of sol. fertilizer salts of the strong acids (HNO_3 , HCl and H_2SO_4) to acid soils, is to increase the sol. acid salts of Al and Fe. Treatment with acid phosphate reduces soil acidity. This is probably due principally to a combination of the sol. H_2PO_4 with the acid salts of Al and the consequent formation of insol. non-acid compds. A new soil acidity method, in which the catalysis of ethyl acetate is taken as the measure of the sol. soil acidity, is used along with the KNO_3 method, and the lime-water method of Veitch.

W. H. FRY.

The determination of availability of nitrogenous fertilizers in various California soil types by their nitrifiability. C. B. LIPMAN AND P. S. BURGESS. Calif. Agr. Expt. Sta., *Bull.* 260, 107-27(1915).—The nitrification studies embraced 29 soil types and 14

different forms of N. The different forms were not always tried with all soils. The low-grade form of N fertilizers, like cottonseed meal, steamed bone meal, goat manure, garbage tankage, and sewage sludge were most readily and economically transformed into nitrates. The high-grade forms, *e. g.*, dried blood, high-grade tankage, and fish guano were not transformed so favorably in the arid soils. However, when plenty of org. matter and an alk. reaction prevail the above materials are changed to better advantage. $(\text{NH}_4)_2\text{SO}_4$ was the most readily available of the inorganic forms.

B. E. B.

The fertilizer value of ashes. R. THIELE. *Gartenwelt* 19, 460-1(1915).—The article gives general information on the compn. and fertilizer value of the ashes of various woods, hard and soft coal and peat. It is much more economical to use artificial fertilizers than ashes. The favorable action of soot is attributed to the protection it affords the vegetation against insects by virtue of its odor, to the increase in the soil heat brought about by its color, and to the NH_4 salts and CaO it contains.

C. F. MILLER.

Combating of hedge-mustard in a new light. L. HILTNER. *Wiener Landw. Ztg.* 65, 380(1915).—Expts. lead H. to believe that the impetus given to crops in fields where weeds have been killed by spraying with FeSO_4 , is to be attributed to the green fertilizing action of the weeds rather than to any action on the part of the FeSO_4 , as is ordinarily claimed. Beside increasing the supply of org., humus-forming substances in the soil, both hedge-mustard and rape gather N, which becomes available to the crop plants soon after they have been plowed under or killed with FeSO_4 soln. The best results are obtained if the spraying is done when the weeds have two or three leaves.

C. F. MILLER.

Further observations on the combating of weeds with kainite and several other chemical agents. T. REMY AND J. VASTERS. *Landw. Jahrb.* 48, 137-69(1915); *Chem. Zentr.* 1915, II, 551; cf. *C. A.* 8, 3702.—Through further expts. the former observations have been fully confirmed. FeSO_4 and CaCN_2 are less effective than kainite.

C. F. MILLER.

Report of the Selby Smelter Commission (HOLMES) 9. Possible sources of potash in America (CAMERON) 18.

Fertilizers. WETCARBONIZING, LTD. *Brit.*, 18,838, Aug. 19, 1914. A dressing for soils is prepd. by subjecting peat while wet to a heat treatment at a temp. of at least 60° without evapn., to render its H_2O readily expressible. The treated peat may be caused to absorb NH_3 .

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Free and combined lactic acid in wine. T. ROETTGEN. *Z. Nahr.-Genussm.* 30, 294-9(1915).—Continuing his work previously published (*C. A.* 8, 547, 1484) R. has detd. free and total lactic acid in 40 different wines, using both the original and a modified Möslinger method for the latter detn. The modified method is as follows: Remove volatile acids from 50 cc. wine by distg. with steam, using a fractionating column containing glass beads and collecting 200 cc. of distillate. Acidify the wine residue with 5 cc. of 1:4 H_2SO_4 and ext. for 24 hrs. with ether in a continuous liquid extractor, add 30 cc. water to the ether ext. and carefully remove the ether by evapn. Add sufficient $\text{Ba}(\text{OH})_2$ soln. to the aq. residue so that it remains slightly alk. after

heating for 15 min. on a water bath, neutralize with 0.25 *N* HCl, evap. to 10 cc. and introduce into a 100 cc. vol. flask, rinsing the dish with 5 cc. of hot water, followed by 95% EtOH, and make up to mark with the latter. Cool to 15°, shaking frequently, allow to remain at that temp. for 1/2 hr., again make up to mark with EtOH, allow to stand for an additional 2 hrs. at 15°, filter into a graduated cylinder kept at 15°, note the vol. of the filtrate, and evap. the latter to dryness in a Pt dish, ignite the residue, cool and titrate with 0.25 *N* HCl, the amt. of the latter required representing the lactic acid present in the aliquot. Free lactic acid was detd. in the same way, omitting the addition of H₂SO₄ to the residue from the steam distn. of the wine. The modified Möslinger method possesses 2 advantages over the original in that the error due to the vol. of the ppt. upon treatment of the Ba salt soln. with EtOH is much smaller, and there is no chance for the formation of EtOH-sol. Ba salts due to heating sugars with Ba(OH)₂. The results obtained upon the 40 wines by the modified method for total lactic acid were in most cases slightly higher (max. 0.04 g. per 100 cc.) than by the original Möslinger procedure, these differences probably being within the limit of exptl. error. Calcd. from the difference between free and total acid no combined lactic acid was found in many of the samples, the balance showing only small amts. (max. 0.04 g. per 100 cc.), which may also be within the limit of exptl. error.

A. F. SEEKER.

Simple working up of raw sugar in the distillery. F. POLEDNIK. *Wiener Landw. Ztg.* 65, 380-1 (1915).—P. has modified the method ordinarily used so that the fermentation only requires approx. 48 hrs. He gives directions for carrying out the process. 1750 kg. potatoes (16% starch), 60 kg. barley and 400 kg. raw sugar yielded 421-3 l. alc.

C. F. MILLER.

Remarks on A. Marbach's new process for the production of yeast from sugar and mineral salts. A. Kossowicz. *Oesterr. Chem. Ztg.* 18, 87 (1915); cf. Marbach, *C. A.* 9, 1967.—Referring to Marbach's claim of credit for this process, K. points to his own work done 14 years ago (*Z. landw. Versuchsw.* 1903) and to Pasteur's work in 1858.

Testing and evaluation of tannin albuminates. D. SCHENK. *Apoth. Ztg.* 30, 577-8(1915); cf. Linke, *Ibid* 1910, No. 66.—Various procedures are discussed and data given covering several commercial samples. W. O. E.

The necessity for more exact procedures in examining medicaments. P. BOHRISCH. *Apoth. Ztg.* 30, 590(1915).—Several examples are given showing the desirability of improving the Ger. Pharm. methods. W. O. E.

Hyoscyamus cultivated in Minnesota: moisture, ash and alkaloidal content. E. L. NEWCOMB AND M. H. HAYNES. *Am. J. Pharm.* 88, 1-3(1916).—It has been found that a satisfactory germination of the seed of *Hyoscyamus niger* biennial may be obtained by treating the seed with concd. H_2SO_4 . Expts. to det. the constancy of this plant have led to the discovery of 2 specimens of known biennial origin which will complete their cycle of growth in 1 season. Moisture, ash, and alkaloidal detns. were made. W. G. GAESSLER.

A comparison of the results secured by the use of the guinea pig and cat methods for the assay of tincture of aconite. CHARLES C. HASKELL AND H. B. THOMAS. *Am. J. Pharm.* 88, 3-7(1916).—The authors conclude that the cat method of Hatcher can be used with good results in the attempt to ascertain the strength of samples of tinctures of aconite; that female cats are more resistant and show greater individual variations to the toxic action of aconite than do male cats; that absorption of aconite apparently occurs readily from the subcutaneous tissues of guinea pigs. A short bibliography is appended. W. G. GAESSLER.

The standardization of drugs by the use of plants. W. M. SAYLOR. *Am. J. Pharm.* 88, 8-12(1916).—Seeds of *Lupinus albus* were soaked in H_2O for 24 hrs., then placed upon sphagnum in a dark place, at a temp. of 18-20°, and allowed to germinate. When the radicles reached a length of 25-40 mm. they were marked, 20 mm. from tips. The seedlings were suspended so that just the growing tip reached below the surface of the soln. Every plant radicle was measured at the end of 24 and 48 hrs., resp., and the amt. of growth recorded. Solns. of strychnine sulfate and strychnine nitrate were used in the following strengths: $1/10$, $1/20$, $1/15$, $1/12$, $1/10$, $1/8$ grain, and then increasing by fifths on up to 2 grains, in 50 cc. of distd. H_2O . With both salts the $1/8$ grain soln. killed the plant in 24 hrs. and the radicle did not advance in length a fraction of a mm., while in the $1/15$ grain soln. there was a growth of $1/4$ -1 mm., and in the 2 grain soln. the radicle had shrunk and did not measure the original 20 mm. from the mark. More or less irregular growths were obtained in the weaker dilns.; nearer to the toxic point a gradual decline in activity and growth is noticeable. The toxic point is definite. A comparison of the strychnine tables with those for distd. H_2O showed that strychnine first stimulated the growth of the plant, but as the solns. grew stronger, the plant weakened, the ultimate result being the death of the plant, just as is the case with animals. For each toxic substance, there is a definite point in strength beyond which the seedling plant under the influence of that substance will not grow or live. Other substances were tried. Expts. using EtOH, U. S. P., in dilns. of 5, 6, 7, 8, 9 and 10%, showed that 8% was toxic in 24 hrs., i. e., the radicle had not advanced in growth. Various dilns. of tinct. of nux vomica, U. S. P., were used; 7 cc. in 50 cc. distd. H_2O killed in 24 hrs. $2\frac{1}{2}$ cc. of fl. ext. of digitalis, U. S. P. VIII (Wyeth), in 50 cc. H_2O , were toxic in 24 hrs. Eight cc. of tincture of digitalis made from this fl. ext. dild. with 50 cc. distd. H_2O were toxic. Six cc. of tinct. digitalis, U. S. P., freed from fat (Wyeth) were toxic. Seven cc. tinc. digitalis (Lilly) (physiologically tested) were toxic. In the case of physiologically tested fl. ext. of ergot, 5 cc. in 50 cc. distd. H_2O were toxic in 24 hrs. Squibb's fl. ext. of ergot (about 6 months old) corresponded to a 95% diln. of the preceding substance. Another fl. ext. of ergot of unknown make,

but known to be a low-priced prepn., was tried; it was about 77% in strength when compared with the physiologically tested prepn. used as a standard. W. G. GAESSLER.

Colloid chemistry and perfume manufacture. P. ROHLAND. *Deut. Parfumerie Ztg.* 1, 116(1915); *Chem. Zentr.* 1915, II, 504.—Some observations on the absorption of odors, dyes, etc., by talc. E. H.

Saffron. KRIZAN. *Boll. chim. farm.* 53, 10(1914).—Examn. of numerous samples of pure saffron established the presence of H_2BO_3 as a normal constituent.

H. S. PAINE.

Chineonal. ANON. *Boll. chim. farm.* 53, 70(1914).—This prepn. is the diethyl-barbiturate of quinine and contains 63.78% of the latter; it occurs as colorless crystals of intensely bitter taste which m. at 132° and are slightly sol. in H_2O and more readily sol. in alc. and $CHCl_3$. Chineonal is recommended as an antipyretic and sedative.

H. S. PAINE.

Ferissol. ANON. *Boll. chim. farm.* 53, 70(1914).—This prepn. is obtained from cinnamic acid and guaiacol powder; it is readily sol. in H_2O . Ferissol may be taken internally in amts. of 0.9–1.0 g. once or twice per day; 0.9–2.7 cc. of a 10% soln. may be used daily for injections.

H. S. PAINE.

Dymal. ANON. *Boll. chim. farm.* 53, 103(1914).—This prepn. is a mixt. of the salicylates of Di, La and Ce; it is an inodorous, pale rose powder which is insol. in H_2O ; it is prescribed in the form of a powder or pomatum and is recommended principally for the treatment of secondary burns and as an antiseptic and exsiccative.

H. S. PAINE.

Eumenol. ANON. *Boll. chim. farm.* 53, 138(1914).—This paper includes a discussion of the history and pharmacological action of eumenol (fl. ext. of the root of a Chinese plant which is variously termed Tang-kui, Tang-kwa, Shan-ki and Won-wu and which is probably a species of *Levisticum* (Umbelliferae). Eumenol is one of the oldest remedies in Chinese materia medica and has been used as an emmenagog; it is non-toxic and free from abortive effects.

H. S. PAINE.

Eucodine. RIEDGL. Berlin. *Boll. chim. farm.* 53, 302(1914).—This prepn. is the bromoethylate of codeine. It possesses the same general properties as codeine, but is less toxic and may be administered in larger doses and with greater frequency.

H. S. PAINE.

Collyrium rubrum. BIRKHAUSER. *Corr.-bl. f. Schweiz. Aerzte* 1914, 863; *Schweis. Apoth. Ztg.* 53, 651(1915).—For a cooling collyrium in chronic conjunctivitis, mix: $ZnSO_4$ 0.04, catechu 0.1, borax 0.04, Bi subnitrate about 0.02 in suspension, H_2O 100.0. To each 50 cc. of the soln. add 1 drop of 3% menthol- $EtOH$. The soln. should be clear.

S. WALDBOTT.

Alival. FARBERKE. Höchst a/M. *Schweis. Apoth. Ztg.* 53, 599, 612–3(1915).—Alival, $CH_3ICH(OH)CH_2OH$, has 63% I; it forms colorless, silky crystals, m. $48-49^\circ$, sol. in H_2O , $EtOH$, Et_2O , less sol. in cold C_6H_6 , $CHCl_3$. Tests for identity and purity, and assay method are given.

S. WALDBOTT.

Theacylon. E. MERCK. Darmstadt. *Schweis. Apoth. Ztg.* 53, 613(1915).—It is a chem. combination of theobromine and $o-AcOC_6H_4CO_2H$, a white, cryst., tasteless powder, insol. in H_2O , $EtOH$, Et_2O , dil. acids, sol. in $CHCl_3$ and dil. alk. It is used as a diuretic in doses of 0.5 g. 3–8 times per day.

S. WALDBOTT.

Atoxicocain. *Schweis. Apoth. Ztg.* 53, 613(1915).—A chem. prepn. identical with novocain which is difficult to obtain in Switzerland.

S. WALDBOTT.

Citobarium. E. MERCK. Darmstadt. *Schweis. Apoth. Ztg.* 53, 629(1915).—This is a form of BaSO_4 producing a milky suspension with water (150–200 g. in 500 cc.), permanent for hrs. It is used in X-ray expts. S. WALDBOTT.

Ampoules. ERNST RICHTER. Frankfurt a/M. *Schweis. Apoth. Ztg.* 53, 633–6(1915).—The testing for solubility in H_2O , the rinsing and the filling are described; the latter is done by the vacuum method under a glass globe of sufficient thickness. Cf. C. A. 10, 87. S. WALDBOTT.

Determination of water in mineral greases (CAMPO) 7. Estimating antimony in stibnite (LEHMANN) 7. Determination of alkaloids (BEAL) 7.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Progress in the principal fields of the inorganic heavy chemical industry. V. HÖBLING. *Chem. Ind.* 38, 340–60, 388–410(1915); cf. C. A. 9, 514, 1976.—A review. F. W. SMITHER.

Recovery of ammonia from waste liquors. E. L. KNOEDLER. *J. Ind. Eng. Chem.* 7, 1061–4(1915).—Waste liquors containing 1% NH_3 from the Welsbach plant, are treated in a continuous still whose operation is largely automatic, and 3000 lbs. of 26% NH_4OH are recovered daily at a cost of \$6.71. H. L. OLIN.

Lime recovery from spent causticizing mud. JAMES H. PAYNE. *J. Ind. Eng. Chem.* 7, 1056–9(1915).—Lime recovery from spent mud is carried on successfully at nearly all the NH_3 -soda works as well as at many beet-sugar plants in the West and proves economical even when lime may be obtained from other sources at \$2.00–\$2.50 per ton. At a typical plant the mud from the causticizing tanks, after the third washing, is sent by centrifugal pump to an agitated storage tank and thence to a rotary vacuum filter. From this the mud, having a solid-liquid ratio of 100 to 45, drops directly into a gas-fired rotary kiln 7 by 120 ft. and is finished in 1.5 to 2 hrs. In using the reclaimed lime 10% must be discarded each day and replaced by new lime to prevent cumulative contamination. Fuel consumption per ton of lime is about 675 lbs. of coal for producers or 9500 cu. ft. of natural gas. H. L. OLIN.

Experiments on the separation of vanadium from crude sodium uranate. H. H. BARKER AND H. SCHLUNDT. *Met. Chem. Eng.* 14, 18–23(1916).—The expts. resulted in at least 4 successful methods: (1) By the action of HCl gas the V is completely removed, leaving a residue of $\text{Na}_2\text{U}_2\text{O}_7$, NaCl , UO_2Cl_2 and other impurities. The U may be removed from this residue by (a) boiling with an excess of NH_4Cl or (b) by dissolving in dil. mineral acid and pptg. with NH_4OH . 59–64% of U_2O_5 is recovered. (2) By mixing uranate with twice its weight of NH_4Cl and enough H_2O to make a thick paste and heating in a porcelain crucible the % of V can be reduced from 8.5 to 0.5%. The % of U recovered may be regulated by the heat treatment, the highest % recovery being obtained where the temp. was not raised any higher than necessary to volatilize the NH_4Cl and V compds. Substitution of NH_4NO_3 for $\frac{1}{4}$ of the NH_4Cl results in as large a removal of V, but also in a lower % recovery of U. (3) V can be completely pptd. by dissolving crude uranate in the least possible amt. of dil. HNO_3 , HCl or H_2SO_4 and boiling the soln. Approx. 13% of the U is pptd. with the V. Recovery of U_2O_5 in the HNO_3 and HCl treatments was 58–79%. Some U is lost in the dil. H_2SO_4 treatment of the residue for the removal of $\text{Na}_2\text{U}_2\text{O}_7$, but may

be recovered by pptn. with NH_4OH . Of the above methods only the NH_4Cl treatment accomplishes the removal of V and the conversion of U_3O_8 in one step. The % recovery of U in all methods is approx. the same. (4) Probably Cl gas may also be used to remove V from carnotite ores quant. by proper regulation of temp.

E. W. BOUGHTON.

Possible sources of potash in America. FRANK K. CAMERON. *J. Frank. Inst.* 180, 641-51(1915); cf. *C. A.* 9, 2293.—Possibilities of potash production from feldspars, from deposits in desert basins such as Searles Lake, from Utah alunite and from the Pacific kelps, are considered. The conclusion is reached that the U. S. has supplies of potash materials more than sufficient to supply domestic needs, that the technology of the subject has been developed sufficiently to prove that the industry can be established successfully so far as physical factors are concerned, but that its commercial success is still in doubt.

Composition for printing forms. A. RËNNER. Ger., 285,534, Aug. 9, 1913. The mass is suitable for stereotyping and may be worked with the etching needle. It consists of a mixt., to be stirred up with H_2O , of alabaster gypsum 2, whiting 2, Zn white 1, cement 1, flour 1, and glue 1 part. The mass is either formed as a thick plate, or poured out as a layer upon a base. The base is flexible if cylindrical stereotypes are to be made.

Refrigeration. G. SCARAMUZZA and E. PEZZI. Ger., 284,906, Nov. 24, 1910. A readily volatile liquid is employed as the refrigerant, and a difficultly volatile, non-freezing liquid, not dissolving the refrigerant, is employed as the conducting medium, both liquids circulating in a closed circuit. The liquids are brought into heat exchange by admixt. in the evaporator, whereby the volatile refrigerant is sepd. from the conducting liquid by volatilization.

Crimped reflectors. M. WISKOTT. Ger., 285,381, Apr. 24, 1914. Addition to 284,611 (*C. A.* 10, 102).

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Identification of trivalent manganese in glass. S. R. SCHOLLS. Univ. Pittsburgh. *J. Ind. Eng. Chem.* 7, 1037(1915).— MnO_2 added to decolorize glass has been assumed to exist in glass as Mn_2O_3 . To show this a low melting glass (sand 100, soda

ash 50, red lead 60 and MnO_2 10) was made. It showed deep violet color. Powdering this glass and treating with HF gave a pink soln. which could be decolorized by $(\text{COOH})_2$ and other reducing agents. A similar pink soln. was also obtained by treatment with 30% H_2SO_4 . To obtain a pink soln. more readily a still more sol. glass was made (sand 100, K_2CO_3 100 and MnO_2 20). Digesting this glass with 30% H_2SO_4 gave a very strong pink soln. Absence of permanganates was shown by failure to get a colored soln. by digesting with H_2O alone. The color also was less violet in tint than permanganate. $\text{Mn}_2(\text{SO}_4)_3$ was prepd. by heating MnO_2 to give brown Mn_2O_3 and treating this with H_2SO_4 . This gave a pink soln. like that from the above glasses. Diln. with H_2O gave in both cases a flocculent brown ppt. and their action toward $(\text{COOH})_2$ was the same. These facts seem to indicate the presence of trivalent Mn in the glass.

C. H. KERR.

Variation in soda, lime and magnesia content of a glass of the type RO_3SiO_2 . C. C. RAND. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 236-9(1915).—The triaxial area $\text{CaO} \cdot 3\text{SiO}_2$ - $\text{Na}_2\text{O} \cdot 3\text{SiO}_2$ - $\text{MgO} \cdot 3\text{SiO}_2$ was covered with the exception of that part above 0.66 equiv. $\text{Na}_2\text{O} \cdot 3\text{SiO}_2$ which was omitted as giving unstable sol. glasses. With less than 0.15 equivs. $\text{Na}_2\text{O} \cdot 3\text{SiO}_2$ the glasses were too viscous to pour. Increase in MgO at the expense of CaO greatly decreased devitrification.

C. H. KERR.

The manufacture of optical glass. C. C. RAND. *Patt. Gaz.* 40, 1236(1915).—The requirements of optical glass are very stringent. A block 12 in. thick must show no color, but light transmission must not be destroyed to any extent. It must be freed from physical strain by annealing. Above 470 – 500° most glasses are sufficiently fluid to permit easy removal of strains. Below 350 – 370° they are too viscous to assume strains. Chem. inhomogeneity, causing striae, is most difficult to overcome. For special lenses a glass of definite index of refraction and definite dispersion is required. At the Bureau of Standards, 25–30 lb. batches are produced without color or strains, and it is hoped that a mechanical stirrer will remove striae.

R. K. HURSH.

The technical control of a window-glass tank furnace. C. J. BROCKBANK. Exolon Co. *Trans. Am. Ceram. Soc.* 17, 222–35(1915).—Tanks must be sharply constricted in width toward the working end. High crowns (over 6–8 ft. above the metal) give poor efficiency. Thin flux blocks are preferable because they allow radiation and consequent lower temp. of the inner side where the glass is in contact with the block. SiO_2 content of window glass should not fall below 70% and the high limit is 74–75%. Fe_2O_3 in the sand should be not over 0.30%. Al_2O_3 in the sand is desirable. CaO should be not over 13.0 and preferably not over 12.5%, as high CaO causes hardness and brittleness and promotes devitrification. High CaO glasses, however, are more brilliant and color-permanent. Since CaO plays an important part in the reduction of Na_2SO_4 a decrease in limestone must always be compensated for by increase in coal. Conditions alter this ratio but approx. $\frac{1}{4}$ lb. of coal must be added for each 3 lb. limestone removed and *vice versa*. The % Na_2O should not fall below 12 unless CaO is below 12 and SiO_2 above 72. Fifteen % Na_2O has been used but 14% should be considered the max. An excess of Na_2SO_4 dissolved in the glass is apt to be thrown out of soln. as sulfate stones. The loss of alkali during melting is usually 0.5 to 1.5%. When analysis shows more than 1% free Na_2SO_4 in the glass, stones may be expected.

C. H. KERR.

Glass manufacture. PAUL SCHNURPFEL. *Glashütte* 44, Nos. 44–52(1914); 45, Nos. 1–32(1915), 31 figs.—S. gives especial attention to ovens and leers.

J. B. PATCH.

The plan and management of a modern enameling factory. WILH. LINKER. *Glashütte* 44, Nos. 14-52(1914); 45, Nos. 1-36(1915). J. B. PATCH.

Note on thermoelectric phenomena observed in some silicates. A. V. BLEININGER. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 218-21 (1915).—Silicates of the formula $RO \cdot 2SiO_2$ are prepared with Mn, Zn, Cu and Fe and formed into small blocks with one smoothly ground surface and with a Pt wire embedded in each. Placing the ground surfaces in contact and heating to temps. of 850-1350° showed potential differences as follows: (a) $ZnO \cdot 2SiO_2 + MnO \cdot 2SiO_2$ from 0.05 millivolt at 900° to 0.65 at 1350°; (b) $ZnO \cdot 2SiO_2 + CuO \cdot 2SiO_2$ from 0.05 at 850° to 1.65 at 1350°; (c) $ZnO \cdot 2SiO_2 + FeO \cdot 2SiO_2$ from 0.02 at 850° to 0.70 at 1200°; (d) Georgia kaolin + $FeO \cdot 2SiO_2$ from 0.05 at 850° to 1.40 at 1200°; (e) Ga. kaolin + $ZnO \cdot 2SiO_2$ from 0.02 at 900° to 1.70 at 1250°; (f) Ga. kaolin + $MnO \cdot 2SiO_2$ from 0.05 at 950° to 3.60 at 1300°. Polarization also was noted increasing with potential difference. This furnishes additional evidence towards the assumption that silicates at higher temps. are partially ionized. C. H. KERR.

Our industry and the foreign trade. CULLEN W. PARMELEE. *Trans. Am. Ceram. Soc.* 17, 55-65(1915).—Presidential address before Am. Ceramic Soc. C. H. K.

Antimony compounds as opacifiers in enamels. HOMER F. STALEY. Iowa State College. *Trans. Am. Ceram. Soc.* 17, 173-89(1915).—Gloss: Sb_2O_3 enamels of good gloss can be made from 3 types of formulas: (1) high B_2O_3 , no PbO; (2) medium B_2O_3 , no PbO; (3) low B_2O_3 with PbO. Color: Sb_2O_3 enamels contain 3 color components; (1) a tan, probably due to S and fading as the smelting continues; (2) a yellow, due to PbO and persistent; (3) a blue, due to a combination of Sb_2O_3 , B_2O_3 , CaO and F, which grows more intense as smelting continues. Opaque whites are produced by controlling the heat treatment and compn. so that the tan and yellow are neutralized by blue. The dark specks in Sb_2O_3 enamels are due to contamination with organic or metallic dirt after the enamel is smelted. The remedy is extreme cleanliness. C. H. KERR.

The relative action of acids on enamel. EMERSON P. POSTER. *Trans. Am. Ceram. Soc.* 17, 137-49(1915).—Tests were made by placing 2 g. of enameled frit (ground in a lab. pebble mill and sieved through 50-mesh) in 100 cc. of the required acid and after standing 24 hrs. the undissolved frit was recovered on a weighed Gooch crucible with asbestos filler and the loss thus detd. That size of grain is of the utmost importance is shown by the following data on the same frit: 50-100 mesh, 0.0522 g. loss; 100-200 mesh, 0.0926 g. loss; through 200-mesh, 0.239 g. loss. Discussion: Shaw pointed out that if clay and other materials such as opacifiers and tempering agents are added to the frit the acid resistance of the frit may not be a fair indication of the soly. of the enamel as used. However, this method of testing shows some decided advantages, especially in factory experimentation. C. H. KERR.

The role of chlorides in the volatilization of ferric iron. GEO. A. BOLE AND R. M. HOWE. Alfred, N. Y. *Trans. Am. Ceram. Soc.* 17, 125-9(1915).—A batch of tin enamel of the following formula was made: 0.2 K_2O , 0.3 CaO, 0.5 PbO, 0.25 Al_2O_3 , 0.08 Fe_2O_3 , 2.8 SiO_2 , 0.15 SnO_2 . To each of several 50 g. portions a known wt. of chlorides of Na, K, Li, Ba, Mg, Pb, Sn and Ag was added in aq. soln. The mix was fused in a muffle kiln at cone 04, the burn lasting 16 hrs. and fusing temp. being held 5 hrs. Analyses were then made (methods are given) and the efficiency factors (% Fe volatilized divided by the % Cl introduced as chloride) were found to be: BaCl₂ 00.00, NaCl 3.76, KCl 3.90, MgCl₂ 4.80, LiCl 4.68, PbCl₂ 14.62, AgCl 14.00, SnCl₂ 18.47. The lower the m. p. of the chloride the greater was its efficiency as a volatilizer of Fe

SnCl_2 being the most active. Other advantages of SnCl_2 are: (1) more complete decompn. at lower temps. than NaCl , thus eliminating trouble from sol. salt in the frit and from decompn. of NaCl during the glaze burn; and (2) freedom from volatilization such as NaCl shows in the salt-glazing process, thus making calcn. of the exact formula possible. SnCl_2 , therefore, is a very valuable ingredient of white enamels.

C. H. KERR.

An unusual case of pinholing of glazes. H. J. KNOLLMAN. *Trans. Am. Ceram. Soc.* 17, 165-72(1915).—The appearance of pinholes is due to too great viscosity of the glaze. While there is undoubtedly more than one cause of pinholing, the sulfuring during water smoking is the main one, since it is possible to use a harder, more viscous glaze when the water smoking is reduced, while a softer and more fluid glaze is necessary when the amt. of moisture is large.

C. H. KERR.

Chrome-tin red glazes between cones 2 and 8. B. S. RADCLIFFE AND C. L. WALDUCK. Univ. Ill. *Trans. Am. Ceram. Soc.* 17, 278-89(1915).—The stain used in all tests was 1 SnO_2 , 1 SiO_2 , 0.075 PbCrO_4 , 2.25 CaO (cf. C. A. 3, 2742) and enough was added to each glaze to introduce 0.118 equiv. SnO_2 . Many trials with wide ranges of compn. were made. The Al_2O_3 to SiO_2 ratio is very important, giving the best red at 1:7. With Al_2O_3 : SiO_2 ratio const. increase in B_2O_3 changed the color from raspberry-red to cherry-red. When PbO replaced CaO the change was from raspberry-red to lilac. Evidently the RO content of the glaze has a decided influence on the color.

C. H. KERR.

White terra-cotta glazes at cones 6 and 7. ERCELL C. HILL. New York. *Trans. Am. Ceram. Soc.* 17, 381-409(1915).—*Gloss:* CaO is essential in this type of glaze, the amt. required to produce max. gloss depending upon the proportions of clay and flint. Excess CaO decreases gloss. If ZnO or small amts. of BaO be then substituted, gloss is again increased. With high CaO increase in ZnO up to 0.30 equivs. decreased gloss in these series. Half of the CaO may be replaced by ZnO . BaO increased gloss if CaO and ZnO were deficient, but decreased gloss when CaO and ZnO were present in sufficient or excess amts. When SnO_2 replaced CaO or ZnO gloss was decreased, but when it replaced BaO there was no change. The lowest clay contents gave the most fusible glazes and the best gloss. The best Al_2O_3 - SiO_2 ratio for gloss was 1:8 to 1:10, the lower feldspar glaze requiring the higher ratio. *Whiteness and opacity:* SnO_2 increased whiteness and ZnO was helpful but to less extent. Replacing CaO by BaO had no effect. Increase in Al_2O_3 decreased whiteness. *Pink coloration:* With SnO_2 pink coloration was common, evidently due to some Ca-Sn combination, low in Sn and high in Ca. Tendency toward pink may be overcome by substituting K_2O , Na_2O or ZnO for CaO . More pink colors were found at lower temps. *Blistering* was due to volatilization of ZnO or some Zn compd. in the glaze.

C. H. KERR.

The use of deflocculating agents in the washing of clays and the effect of the process upon the color. G. H. BROWN AND W. L. HOWAT. Pittsburgh, Pa. *Trans. Am. Ceram. Soc.* 17, 81-90(1915).—Using Am. kaolins even after sieving through 200-mesh gave black specks and body color inferior to European products. Increasing the degree of dispersion by adding alkali in the washing process greatly improved the color of Georgia kaolin and to a less extent the color of N. Carolina and Florida kaolins. The amts. of NaOH giving best results were, resp., 0.17, 0.19 and 0.14%. This use of the alkali decreased drying shrinkage considerably (especially with Ga. kaolin) and increased burning shrinkage at cone 10 noticeably, except in the case of the body made from Ga. clay (clay 50, flint 30, feldspar 20). The burning shrinkage of Ga. clay alone, however, showed increase due to the use of the deflocculent.

C. H. KERR.

Tests of Iowa fire clays. M. F. BEECHER. *Trans. Am. Ceram. Soc.* 17, 102-24 (1915).—Twenty-three representative fire clays of possible com. importance were examd. Fusion points were mostly between cones 18 and 27, total range being cones $4\frac{1}{2}$ and 30. Warpage was detd. on slabs $\frac{1}{2}$ in. $\times$ 1 in. $\times$ 9 in. On the basis of fusing point and warpage, 10 clays were selected for further study and burning shrinkage, porosity and sp. gr. were detd. at cone 04 to 10 and load tests were made. All data are tabulated. Results show that for tests of fire clays in general, the load test, warpage, fusion point and porosity give all the necessary information. C. H. KERR.

Laboratory methods for the physical testing of fire clays. C. H. KERR, R. J. MONTGOMERY AND C. E. FULTON. *Trans. Am. Ceram. Soc.* 17, 91-101 (1915).—Details of testing methods are given for the examn. of raw clays: (a) description, (b) sieve test, (c) sp. gr., (d) plasticity, (e) drying shrinkage, (f) modulus of rupture; and for burnt clays: (g) burning shrinkage, (h) modulus of rupture, (i) apparent porosity, (j) apparent sp. gr., (k) true sp. gr., (l) open and closed pores (all tests g, h, i, j, k, l, at various temps.), (m) fusion point. C. H. KERR.

The effect of saturated sodium sulfate solution upon the structure of clay burned to different temperatures. W. L. HOWAT. Bur. Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 249-55 (1915).—As an accelerated test of the resistance to disintegration by the weathering effects of freezing and thawing the Brard test is used. Test pieces were immersed in saturated Na_2SO_4 soln. at room temp. for 24 hrs. and then dried at 110° . This was repeated 4 times. Room temp. (and not above 33°) was used because at 33° the $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ becomes anhydrous. This crystn. test disrupts burnt clay wares quickly and gives sharp and decisive results; possibly it is too severe. Perhaps a modification using lower concn. (say 10%) would be better. No direct comparison with freezing and thawing has been made. Three clays were tested after burning to 900-1200°. The temp. of burn that produced successful resistance to 4 tests as above were: (a) surface clay, 1050° ; (b) shale, 1050° ; (c) No. 2 fire clay, 1100° . C. H. KERR.

The effect of grog in a fire clay body. C. E. FULTON AND R. J. MONTGOMERY. Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 410-21 (1915).—Using St. Louis fire clay raw and burned (grog) trials were made with 0, 25, 50 and 75% grog. Increasing the grog caused: (1) decrease in H_2O required for plastic mass; (2) decrease in linear shrinkage; (3) decrease in strength of raw body; (4) decrease in burning shrinkage and also a decrease in the tendency to overfire at cones 15 and 20; (5) decrease in strength of burned ware; (6) increase in sp. gr. of burned ware; (7) increase in porosity of burned ware. Using 50% raw St. Louis fire clay and 50% burnt sieved through Tyler Standard Screens of 6-, 14-, 35-, 100- and 200-mesh showed that increasing the fineness of the grog (1) increased the H_2O required for plastic mass; (2) increased drying shrinkage; (3) increased strength of raw mass; (4) increased burning shrinkage except at cone 20 with 100- and 200-mesh grog where overfiring more than counteracted increased burning shrinkage; (5) increased strength of the burned body (up to cones 15 and 20 where overfiring decreased the strength); (6) affected the sp. gr. of the burned mass very little; (7) increased porosity up to cone 5, at cone 10 showed very little effect and at cones 15 and 20 decreased the porosity except with the 100- and 200-mesh grog where overfiring again caused increase. C. H. KERR.

Influence of varying water content in a fire-clay mixture. R. J. MONTGOMERY AND C. E. FULTON. Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 437-50 (1915).—Using St. Louis fire clay alone and with 50% burnt clay of the same kind, mixtures were made with 19.1, 21.5, 24.5 and 27.0% H_2O for the raw clay, and 14.1, 16.5, 19.0 and 21.5%

H₂O for the 1/2 grog mixtures. Trials were burned to cones 010-20. The results showed that variation in H₂O content had considerable effect on the drying shrinkage but comparatively little effect on the physical properties of the burned mass. *Discussion.* Purdy held that the amt. of H₂O used is much more important than here indicated.

C. H. KERR.

Feldspar possibilities in Georgia. S. L. GALPIN. Iowa State College. *Trans. Am. Ceram. Soc.* 17, 373-80(1915).—The materials are very promising but transportation costs are high.

C. H. KERR.

Development of shivering in a fire-clay body. R. H. MINTON. *Trans. Am. Ceram. Soc.* 17, 310-3(1915).—Expts. showed that adding SiO₂ quickly caused shivering. In many cases shivering has been attributed to sol. salts in the grog used when it was due to silicious material brought in.

C. H. KERR.

Magnesite bricks. ANON. *Brit. Clayworker* 24, 161(1915).—Grecian and Austrian magnesite are best. The rock is calcined to about 1780°, sorted, ground, mixed with light, burnt magnesite and water and pressed in semi-dry form. English bricks are fired to cone 17-18; best Austrian and German 50° higher; best Grecian to cone 35.

C. H. KERR.

The use of barium fluoride for the prevention of drier scum on bricks. HOMER F. STALEY. Iowa State College. *Trans. Am. Ceram. Soc.* 17, 200-4(1915).—BaF₂ is recommended in place of other Ba compds. The advantages are: (1) lower cost, (2) greater soly. than CaCO₃, (3) smaller amts. required, (4) absence of harmful effects on color, (5) absence of scum due to excess, and (6) promotion of vitrification.

C. H. KERR.

Results of compression tests on porcelain base. J. W. WARD. *Trans. Am. Ceram. Soc.* 17, 432-7(1915).—Factory expts. showed that it is possible to get high crushing strength in a com. porcelain body but it is very essential in assembling the parts to avoid breaks or air spaces in the joints.

C. H. KERR.

The viscosity of porcelain bodies. A. V. BLEININGER AND C. S. KINNISON. Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 130-6(1915); cf. *C. A.* 8, 804, 3225.—With high feldspar bodies (30-65%) the effect of higher feldspar content was greatly to increase viscosity, especially in low clay bodies. A slight decrease in viscosity is noted in the 40% clay series when all of the flint is replaced by feldspar. With 45% clay, feldspar contents of 35 and 40% are most effective in decreasing the viscosity. Higher % again increases it. A still higher clay content causes the softening effect of the feldspar to diminish decidedly. Flint in such high feldspar bodies is not an important factor in governing viscosity. The greatest rigidity is evidently due to the high clay content. High clay bodies having feldspar as the only other constituent showed very great viscosity. The function of viscosity is not a continuous one but changes in irregular stages. The most useful data are obtainable at 1300-1345°. C. H. K.

Dental porcelains. ARTHUR S. WATTS. Ohio State Univ. *Trans. Am. Ceram. Soc.* 17, 190-9(1915).—A porcelain body claimed to be successful showed a compn. equiv. to: K₂O 0.74, Na₂O 0.26, Al₂O₃ 1.14, SiO₂ 7.830, TiO₂ 0.002; this may be expressed in mineral compn. as feldspar 81, clay substance 4, flint 15%. Another com. dental porcelain is said to contain 80% feldspar and 20% quartz fused at cone 9, finely ground and mixed with 5% bone ash. Inlay porcelains are of various types ranging from the above to easily fusible enamels. These porcelains are supplied to dentists in powdered form to be mixed with H₂O and burned. One such powder showed a compn. equiv. to: K₂O 0.70, Na₂O 0.18, CaO 0.12, Al₂O₃ 0.700, Fe₂O₃ 0.014, SiO₂ 6.840.

TiO_2 0.014; this corresponds to the following mineral compn.: feldspar 89.50, Na_2CO_3 4.00, CaCO_3 2.70, flint 3.80%. A softer porcelain contained: K_2O 0.638, Na_2O 0.141, CaO 0.221, Al_2O_3 0.565, Fe_2O_3 0.090, SiO_2 5.900, B_2O_3 0.023, TiO_2 0.011; this may be expressed in mineral compn. as feldspar 61.06, K_2CO_3 1.98, Na_2CO_3 1.98, CaCO_3 4.21, borax 0.83, flint 29.07%. A com. "silicate cement" used for inlay work showed analysis of the powder as follows: ignition loss 2.00, SiO_2 37.00, Al_2O_3 32.20, CaO 7.50, Na_2O 10.10, P_2O_5 1.90, F 9.30, and of the liquid-solid content 41.50% (consisting of Na_2O 6.00, P_2O_5 35.50). The powder is isotropic and uniform in n_D , showing that it had been fused. Manufacturing methods of the Dentists' Supply Co., York, Pa., are given. Pure K feldspar is crushed to $1/4$ -in., hand-sorted and ground in drag mills. It is then mixed with quartz and kaolin. Since the % clay is low, starch and gum arabic or gum tragacanth are added. Coloring material is added to give the desired shade.

C. H. KERR.

The Bureau of Standards contrast method for measuring transparency. IRWIN G. PRINER. U. S. Bureau of Standards, Washington. *Trans. Am. Ceram. Soc.* 17, 150-64(1915).—If a black and a white figure placed side by side be covered by a translucent medium the contrast in color is reduced; this is used as a basis of measuring transparency. The standard white is a MgO surface (a deposit of smoke from burning Mg ribbon). The black is an acetylene smoke surface in the bottom of a black lined cavity viewed through a hole in one side. The brightness ratio is measured by the Martens (or Beckstein) photometer. An interesting discussion is given of its application to pottery.

C. H. KERR.

The value of specific gravity of raw materials. D. E. HUMPHREY. *Trans. Am. Ceram. Soc.* 17, 215-7(1915).—Sp. gr. is used in various calcns. involving wts. per cu. ft.

C. H. KERR.

Importance of the sagger-making department. GEO. SIMCOE. *Trans. Am. Ceram. Soc.* 17, 256-73.—S. wrote to most of the N. J. producers and tabulates data received, concluding that: (1) certain clays have properties other than ability to stand high temps. that make them very valuable for saggars; (2) SiO_2 , whether added in coarse grains as grog, or fine as sand or sandy clays, is a detriment rather than a help in sagger bodies; (3) materials other than those normally used in sagger bodies may be added with great benefit.

C. H. KERR.

Seger cones. ANON. *Brit. Clayworker* 24, 168(1915).—Analyses and compn. of German seger cones are given together with analyses of the raw materials used.

C. H. KERR.

Notes on the manufacture of plaster molds. GEORGE A. WILLIAMS. *Trans. Am. Ceram. Soc.* 17, 323-9(1915).—The effect of varying the amt. of mixing H_2O and the influence of retarders and accelerators on porosity and strength were studied. Temp. curves during setting were taken and transverse tests made. Hardness was measured by the time required for a jet of water to wear a hole through a slab $13/16$ in. thick. The most favorable amt. of H_2O for pottery plaster (showing max. porosity and nearly max. strength) was 1 qt. to $2\frac{3}{4}$ lbs. plaster. By the use of accelerator or retarders strength is increased at the expense of porosity or vice versa.

C. H. K.

The present status of the producer-gas-fired continuous kiln in America. R. H. McELROY. *Trans. Am. Ceram. Soc.* 17, 274-7(1915); cf. C. A. 8, 2611.

C. H. KERR.

Experiences in mending kiln furniture. SAMUEL RUSOFF. *Trans. Am. Ceram. Soc.* 17, 290-3(1915).—Na silicate or plastic clay alone are not successful. Slip clay

lacks initial bond but is good when heated. The best compn. is waste mix (or fine grog 40-60 mesh) 55, slip clay 5, fire clay or ball clay 20, Na silicate (J brand 42% H_2O) 20. The silicate is dild. to 38° Bé. before use. The clay wares are cemented together, dried and then heated to 500° F.

C. H. KERR.

Notes on casting. A. V. BLEININGER AND M. R. HORNING. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 330-54(1915).—For flowage measurements on casting slip the efflux viscosimeter is satisfactory. For reducing viscosity Na silicate is more effective than Na_2CO_3 . Because of comparative coarseness N. Carolina kaolin is more greatly influenced. Georgia kaolin shows far greater initial viscosity than that from N. Car. and is very sensitive to Na_2CO_3 additions. It shows a well-defined minimum in viscosity which turns rapidly toward a maximum. This min. viscosity range is greater when Na silicate is used. Tenn. ball clay No. 3 has no decided min. viscosity point, probably due to the comparatively large amt. of pseudo-emulsoïd or lyophile substance produced. A large vol. of air seems to be absorbed in slips; the removal increases viscosity. Vigorous stirring is necessary and vacuum might be beneficial. A body containing N. Car. kaolin, Florida kaolin and Tennessee ball clay proved to respond well to the addition of Na_2CO_3 but showed a turn towards greater viscosity (recoagulation) for additions greater than 0.06%. A com. slip, fairly high in English ball clay, showed rapid drop in viscosity, but required a much higher % of the reagent mixt. than the single clay bodies. The viscosity seemed to remain const. at the min. value. It is possible that this condition is due to the presence of org. colloids which exercise a protective influence. Interaction occurs between different clays with respect to viscosity changes, independent of the alk. additions, and irregular in nature. Some clays may have a detrimental effect upon the others in making up a casting body. The ball clay content in a casting slip should be reduced to the min. Absorption of the alk. reagents is important. NaOH is absorbed to a far greater extent than Na_2CO_3 and probably combines chemically with the clay. The tensile strength of cast bodies containing alk. additions may be greater than that of the same materials cast without these reagents. Single clay body-slips, used in the state of max. deflocculation do not seem to be weaker than when the suspensions are only carried to a point just under min. viscosity. The general formula: $\eta_1 = \eta (1 + kf)$, where f = ratio of vol. of dispersed particles to total vol. of system and in which k is detd. for each of a series of concns. might prove useful for interpolation purposes, provided the alkali addition is kept const. Casting bodies with low concn. of alkali are more apt to change their viscosity with time than those containing large additions.

C. H. KERR.

Time-temperature curves during salting of some oil-fired sewer-pipe kilns. F. H. RIDDLE AND A. L. GLADDING. *Trans. Am. Ceram. Soc.* 17, 314-22(1915).—Sufficient heat to volatilize the NaCl and proper draft are the 2 essentials. Reducing conditions have as much effect as the salt, or even more, in causing fall in temp. The reducing condition is caused by lowering the damper so as to cut off the air supply.

C. H. KERR.

Production and use of barium compounds (EMLBY) 18. Formation of some basic silicates (CAMPBELL) 20.

Imitation stained glass. W. GROSSHEIM. *Ger.*, 285,126, Aug. 3, 1913. Addition to 272,458 (C. A. 8, 2813).

Handling bottles during manufacture. A. GUTMANN AKT.-GES. FÜR MASCHINENBAU. *Ger.*, 285,300, Dec. 14, 1913.

Stoneware. SPECIALFABRIK FÜR GESUNDHEITSTECHNISCHE EINRICHTUNGEN E. KATZENBERGER. Ger., 285,483, Dec. 23, 1913. The ware is provided with hollow double walls, and these are filled with cement or beton, and the strength is increased further by Fe inserts. These metal inserts can be made to serve in fastening the articles to the wall.

Finishing tiles. AKT.-GES. NORDDEUTSCHE STEINGUTFABRIK. Ger., 285,255.

Glazed clay plates by wet pressing. G. KOCH. Ger., 285,341, Nov. 8, 1913.

Brick presses. T. GROTH AKT.-GES. Ger., 285,339, July 10, 1914.

Control of automatic brick cutting presses. C. KELLER & Co. Ger., 284,307, Aug. 27, 1913. Addition to 281,126.

Regulation for worm presses for clay. A. LUTZE. Ger., 284,596, Sept. 10, 1913.

Handling fresh clay goods. W. BRUDERER. Ger., 285,450, May 10, 1914.

Mica stone. C. INGVALDSEN. Ger., 285,482, Oct. 8, 1913. Mica may be formed readily into block, plates and the like of any form and size by mixing finely divided mica with only so much clay or other addition of similar properties that a coherent formless mass is just obtained. This mass is formed as desired, and burned. The burning is effected at a temp. which results only in a sintering of the mica-clay mixt. The product possesses practically the same properties as the natural mica. In order to secure still greater resistance to higher temps., a mixt. of equal parts of mica and pulverized quartz is employed instead of the mica alone, and a small amt. of clay is added. This mixt. is shaped and burned until the mica melts. A homogeneous mass of great refractory properties is obtained which is also elec. insulating. A stone prepd. in such manner is recommended for use in elec. melting furnaces, carbide furnaces, and the like.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

The formation of some basic silicates. E. D. CAMPBELL. *Trans. Am. Ceram. Soc.* 17, 66-80(1915); cf. *C. A.* 7, 3400; 9, 703.—In Portland cement, alite (chiefly $3\text{CaO} \cdot \text{SiO}_2$) is the chief constituent, the second in importance being celite, the imbedding magma. Flat disks of clinker made from Lehigh Valley mixt. were burned to $1525\text{--}1550^\circ$. Pure MgO slabs were prepared and placing one above and another below the clinker disks; these trials were burned at various temps. from 1475 to 1575° , the temp. in each case being held within 5° for $2\frac{1}{2}$ to 13 hrs. After such burns the MgO disks were discolored and nearly satd. with the fluid constituent of the clinker. Analysis and calcn. of the mol. ratios showed that: (1) although the proportion of Fe_2O_3 to Al_2O_3 is a little higher in celite than in alite, the difference is not great, and the assumption that Fe_2O_3 is molecularly equiv. to Al_2O_3 , so far as the formation of celite goes, seems justifiable, although the hydraulic properties of the aluminates and ferrites differ; (2) with a given basicity of the entire mass the proportion of SiO_2 to $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ in the celite increases with temp.; (3) with a given temp., the proportion of the SiO_2 to the $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ in the celite decreases as the basicity of the entire mass increases. From these facts the following hypothesis was derived: (1) Celite consists essentially of a Ca aluminate, fusible a little above 1400° and capable of dissolving when liquid, $\text{CaO} \cdot 2\text{SiO}_2$ and CaO . The CaO is more readily sol. and the solubilities of $\text{CaO} \cdot 2\text{SiO}_2$ and CaO follow laws similar to those which govern the soly. of salts in

liquid soln. (2) The alite consists essentially of either α or β CaSi_2O_6 holding in solid soln. CaO with some Ca aluminate and ferrite. The concn. of the CaO held in solid soln. is dependent upon the basicity of the mass as a whole, and upon the temp., but the limit of soly. apparently is reached when the proportions required to form the usually accepted $3\text{CaO} \cdot \text{SiO}_2$ have been reached. It may be very fruitful to ceramic investigations to conceive the process as consisting of a series of solns. followed by recrystn. from a fusible solvent, until chem. equil. is reached if sufficient time is allowed.

C. H. KERR.

Tests on the inflammability of untreated wood and of wood treated with fire-retarding compounds. R. E. PRINCE. U. S. Forest Products Lab. *Proc. National Fire Protection Assoc.* 1915, 106-49.—An extensive series of tests on the inflammability of wood, on the methods of rendering it fire-retardant by the use of fire-retarding paints and on the injection of chemicals is being made. Small blocks of 11 species of wood were tested untreated. Western red cedar shingles and cypress siding were tested untreated, after painting with various paints and after treatment with the following chemicals: NH_4 -phosphate, -sulfate, -chloride and -alum, $\text{Al}_2(\text{SO}_4)_3$, ZnCl_2 borax and Zn borate. Oxalic acid, Na_2CO_3 and NaHCO_3 were also used on small blocks of noble fir. An app. was developed for testing inflammability. From the data obtained to date it appears that: (1) There was very little variation in the inflammability of the various untreated woods when tested at high temps. (2) NH_4 salts, borax and Zn borate gave better results than the other chemicals. (3) None of the injected chemicals prevented glowing or charring of the wood when it was continuously heated. (4) Wooden shingles may be made fire-retardant by injecting certain chemicals. Painting after treatment is necessary to prevent leaching if sol. salts are used. (5) The pptn. of insol. metallic borates in shingles appears to be the most practical method studied. (6) All the paints tested increased the fire resistance of shingles to some extent. The most effective paint tested, which was suitable for outside use, was one containing Zn borate pigment. (7) Shingle stains did not greatly increase the inflammability of shingles. (8) Paints for interior use were in general more effective than paints for outside use. Detailed descriptions of app. methods of testing and results are given. The work is being continued.

GEO. M. HUNT.

Saving creosote oil in the treatment of piling. C. H. TRESDALE. U. S. Forest Products Lab. *Wood Preserving* 2, 63(1915).—The small end of piling absorbs more oil per cu. ft. than the rest, although it is driven into the mud and needs no protection. The large end is cut off after driving and also needs no protection. Expts. show the possibility of retarding penetration in these portions and thus saving preservative, by leaving the inner bark on them when the rest of the pile is peeled, or by applying special paints. The length which can safely be left untreated must depend on the conditions under which the piling is to be used. Further expts. are desirable.

GEO. M. HUNT.

The preservative treatment of farm timbers. GEO. M. HUNT. U. S. Forest Products Lab. *Wood Preserving* 2, 67-8(1915); cf. *C. A.* 9, 1987.—Coal-tar creosote is generally used for farm timbers. Tar, crude oil, paint, linseed oil, and whitewash cannot be depended upon to prevent decay. Open tank treatment is the most effective and most expensive method suitable for farm use. Dipping and brush treatment may also be used.

GEO. M. HUNT.

Oxychloride cement. L. PINK. *Ger.*, 285,369, Dec. 19, 1913. The object of the process is to prep. the initial material for the manuf. of sorel cement in the form of a dry, slightly hygroscopic powder, ready to mix. This is accomplished by the dry

mixing of MgO and SrCl_2 , with or without anhydrous MgSO_4 . In the latter case, the liquid MgCl_2 forms only upon mixing the powder. The dry powder is mixed with H_2O *in situ* to a slurry which hardens later. The pulverulent mixt. may be transported readily in sacks, and may be stored, if due precautions be taken, without alteration. The MgSO_4 is best used in the form of the monohydrate. In combination with filling material, the mixt. serves for the manuf. of continuous floor surfaces, and without filling it serves other purposes. The SrCl_2 has the advantage over CaCl_2 and MgCl_2 of less fluidity, and over BaCl_2 of being non-poisonous.

Artificial stone. C. H. SCHOL. Ger., 285,316, Dec. 25, 1912. A porous stone is made from blast furnace slag. Cf. C. A. 9, 1837.

Artificial stone. C. SCHNEIDER. Ger., 285,602, May 11, 1913. A rough stone is made from cement and comminuted combustible matter. The outer layer, alone, of the shaped mass contains the combustible matter, so that upon burning, the combustible matter is completely burned before sintering can take place.

Roofing paper. SCHATZ & HÜBNER. Ger., 284,886, Oct. 23, 1913. Coarse paper is satd. with a mixt. of coke-oven tar, Mexican asphalt, charcoal pitch, and brown-coal tar oil. E. g., the coke oven-tar is heated to about 120° , and for every 100 parts are added about 7 parts charcoal pitch, 5 of brown-coal tar oil, and 25 of Mexican asphalt, the mass is stirred thoroughly, and the paper is satd. with the product in the usual manner. The resulting material is smooth and lustrous and stronger than the products obtained by other processes.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Final report of the joint committee on coal analysis of the American Society for Testing Materials and the American Chemical Society. W. A. NOYES, *et al.* *Proc. Am. Soc. Testing Materials* 15, Pt. I, 454-5 (1915).—Investigations have been carried out by sub-committees on (1) prepn. of sample, (2) moisture, (3) deterioration, (4) volatile matter, (5) fixed C and ash, (6) S, (7) P, (8) ultimate analysis, (9) calorimetric detn. See following abstract.

H. L. OLIN.

Report of Committee E-4 on methods of laboratory sampling and analysis of coal. S. W. PARR, *et al.* *Proc. Am. Soc. Testing Materials* 15, Pt. I, 453, and *Year Book* 1915, 596-624.—The committee proposes numerous modifications of the official methods (*J. Am. Chem. Soc.* 21, 1116 (1899)). Dry the lab. sample, if wet, at room temp. or in a special oven (cf. Stanton and Fieldner, *Tech. Paper* No. 8, Bur. Mines) $10-15^\circ$ above room temp., crush to 20-mesh and take a 60 g. moisture sample (a), riffle the remainder to 120 g., crush to 60-mesh, riffle to a final 60 g. sample (b), and transfer it to a 4 oz. rubber-stoppered bottle. Det. moisture on both a and b, after heating the capsules and cooling over H_2SO_4 by heating for 1 hr. in an oven with toluene bath, through which passes a current of air dried with concd. H_2SO_4 . Det. volatile matter by heating a 1 g. sample in a Pt crucible fitted with a capsule cover, in an electrically heated furnace (cf. Fieldner, *Tech. Paper* No. 76, Bur. Mines, p. 21) at $950^\circ (\pm 20^\circ)$ for 7 min. For fixed C and ash, place the porcelain capsules containing the dry sample in a cold muffle furnace, heat gradually to redness, and finish at $700-750^\circ$. Cool in air if the coal is free from CO_3 .—Det. S by the Eschka method. To det. P add 10 cc. HNO_3 and 3-5 cc. HF to the ash from a 5 g. sample, evap. the liquid and fuse the residue with 3 g. Na_2CO_3 . Acidify the filtrates from the leachings with HNO_3 , add molybdate soln. and det. PO_4 — as usual. Directions for detg. calorific values,

involving the refinements common to all accurate work of the kind, are given in detail. The total rise of temp. R due to combustion is $t_c = r_2(c - b) - (t_a = r_1(b - a))$ where r_1 is rate of rise per min. for 5 min. before firing, r_2 rate of cooling of final 5 min. after firing, a the time of last temp. reading before firing, b the time when the rise in temp. has reached 0.6 of the total, c the time of thermometer reading taken when temp. change has become uniform 5 min. after firing, and t_a and t_c temps. at times a and c . The radiation factor $r_2(c - b)$ is added if the temp. is falling at time c , subtracted, if rising; $r_1(b - a)$ is added if temp. is rising at time a , subtracted if falling.

H. L. OLIN.

A critical review of the method employed for determining heats of combustion. STANLEY ROBSON. *J. Gas Lighting* 132, 431-2, 478-9, 532-4, 583-5, 635(1915).

E. H.

Reaction between gas and pole in the electrical ignition of gaseous mixtures. W. M. THORNTON. *Proc. Roy. Soc. London (A)* 92, 9-22(1915); cf. *C. A.* 8, 3498.—Mixts. of C_2H_4 or CO with air have been ignited by break sparks in mixts. in which the % has been varied at atm. pressure, and by long and short jump-sparks in a const. mixt. and varied gas pressure. The limits of inflammability for C_2H_4 are 3.1 and 10.7% in air, of CO 14 and 71%. Electrodes of Pt, Ni, Cu, Al, Fe and C were used. The metal of the sparking points has a great influence upon ignition, at pressures up to an atm., whether the sparks are disruptive or formed by sepn. of the electrodes. The order of difficulty of ignition by continuous-current break-sparks is that of the density of the poles; that by jump or long disruptive discharge sparks varies with the tenacity of the material of the poles; that by alternating or condenser discharge sparks is proportional to the rates of heating of the points of contact. With C poles condenser discharge in coal gas has the most effect upon the H; longer disruptive discharge upon the CH_4 .

E. B. MILLARD.

Coal storage for gas works. A. WEIGEL. *J. Gasbel.* 58, 375-6(1915).—The advantages of closed silos are (1) no deterioration of the coal from weathering, (2) low operating costs for handling coal to and from storage, (3) less space required, (4) more opportunities for the elimination of hand labor. W. describes the silo for the gas plant at Posen where space was limited. The plant consists of horizontal chamber ovens, and the silo is built over the ovens and forms the roof of the oven building. Foundations were expensive but saving of space more than offsets this. The coal goes from cars or barges through rolls and then directly to the silo. The floor of the silo has provisions for insulation and ventilation to prevent overheating the lower layers of coal. A drawing of the plant showing the coal handling system is included.

W. L. BADGER.

Colliery power and by-products from unsalable fuel. M. H. MILLS. *Gas World* 63, No. 1628; *Coking By-Products Section* 19-20(1915).—A discussion of the use of rough slack coal as employed in a Mond producer to generate gas which is utilized in two 200 h. p. engines at a cost of 0.3 d. per unit including depreciation of plant. About 62 cu. ft. of gas are obtained from each lb. of fuel and about 80 lbs. of $(NH_4)_2SO_4$ and 4 gals. of tar from each ton. M. also discusses the use of "butts" or interstratified coal and shale picked from the colliery screenings as used in Kerpely producers. Av. results and description of operation are given. M. L. TROWBRIDGE.

Recent advances in generator gas technic. GWOSDZ. *Feuerungstechnik* 4, 4 (1915).—A review of recent improvements in generator construction, particularly for increasing the yield and recovery of the by-products.

H. R. GUNDLACH.

Comparison of yield and costs of different methods of operating vertical retorts. W. SCHWEIZER. *Düsseldorf. J. Gasbel.* 58, 438-9(1915).—The plant consists of 7

Dessau settings of 10 retorts each, and horizontal chamber ovens. The problem was to produce 2,850,000 cu. ft. of gas daily, with a heating value of 595 B. t. u. per cu. ft. (at 0° and 760 mm., dry gas) and to use as few of the chamber ovens as possible. Plan (a) was to charge the vertical retorts every 12 hrs., use steam in them, and add as much water-gas as possible without going below the required heating value. Plan (b) was to charge the retorts every 10 hrs. and operate them without steam. It was found that (b) gave nearly the same amt. of gas from the vertical retorts as (a), but of enough higher heating value that 190,000 cu. ft. more water-gas per day could be added. The result was about 7% more gas of the same quality by method (b). Comparisons show that (b) costs 24 cents more per 1000 cu. m. than (a). W. L. BADGER.

Blue water-gas and deep-fuel combustion. A. G. GLASGOW. *Am. Gas Light J.* 104, 23, 26-7(1916); see *C. A.* 10, 112. E. H.

Heating experiments with gas coke and metallurgical coke. H. MARKGRAF. *J. Gasbel.* 58, 408-9(1915).—A criticism of the results and conclusions of Otto (*C. A.* 9, 2144) and a reply to M. by Otto. W. L. BADGER.

Gas lighting and hygiene (GRUBER) 14.

22. PETROLEUM, ASPHALT, AND WOOD PRODUCTS.

F. M. ROGERS.

The cracking and distillation of petroleum under pressure. B. T. BROOKS. *J. Frank. Inst.* 180, 653-72(1915).—A review and discussion of patented processes together with expts. on them. A sample of the liquid product (obtained by compressing 1000 cu. ft. of the gas) used for the manuf. of Pintsch gas and obtained by cracking petroleum at high temps. (900°) showed: d. 0.830, distg. below 115°, 88%, treated with cold concd. H_2SO_4 , loss = 48%. The principal constituent of the remainder was C_4H_4 . Expts. on Texas solar oil (d. 0.8862) within the temp. range 430° to 600° yielded 3 to 20% of gasoline boiling below 150°; the product was highly unsatd., the loss on treating with 0.2 vol. of concd. H_2SO_4 averaged about 28%. Contact substances appeared to be without effect, except in the case of Ni, when the amt. of gas produced was greater and the gasoline fraction of the resulting product showed a much greater loss to the H_2SO_4 than when other contact substances were employed. B. has found $HCHO$ and $HCOOH$ among the products of the auto-oxidation of cracked oils, indicating the presence of the group = CH_2 . Ordinary desulfurization methods leave traces of S that soon render the catalysts (Ni and Pd) inactive. In view of the recently proposed method of Bergius, of hydrogenating without a metallic catalyst, an expt. was made in which a sample of cracked gasoline (I no. 55.0) was maintained at 196° for 30 hrs. under a H pressure of 3000 lbs. per sq. in. The I no. after the expt. was 52.9, due to polymerization since a similar reduction occurred in an atm. of N. Cracked oils, desulfurized and otherwise purified by metallic Na, held their H_2O -white color and were decidedly better, even in odor, than good com. "primary" gasoline, after the 2 samples had been exposed side by side to light and air for 6 months. The same marked difference was noted in the case of a sample of "primary" gasoline from Oklahoma crude, part of which was treated with Na and the second part "refined" by H_2SO_4 in the usual manner. S compds., perhaps in the sulfite condition, appear to catalyze the auto-oxidation of such refined oils. Results with the steam-Fe method indicate that hydrogenation of olefins under these conditions is inappreciable. In

order to compare the results obtainable by heating under pressure and subsequently distg. at atm. pressure, Oklahoma reduced oil, containing no constituents boiling below 275° , was heated for 2 hrs. under a pressure of 180 lbs. per sq. in., the pressure being that developed by its own vapors and decompn. products. Subsequent distn. at atm. pressure yielded 5% gasoline. In another expt. in the same app., with the same quantity of reduced oil, for 2 hrs. at 180 lbs., 30% of gasoline was obtained by distg. the gasoline as fast as formed. Continually increasing yields of gasoline up to about 250 lbs. per sq. in. were obtained; with further increase of pressure the yield diminished, the relative amt. of coke and gas formed rapidly increasing. The marked influence of pressure upon the percentage of olefins in the gasoline produced is shown graphically. This decrease in the percentage of olefins in the resulting gasoline is due to their polymerization, not to hydrogenation. Analysis of the gases evolved during distn. of Oklahoma reduced oil at 110 lbs. press. shows the percentage of H to be extremely small. Higher temps. are required to "crack" paraffin than a mixt. of the cyclic hydrocarbons or naphthenes. Paraffin is more stable toward Al_2Cl_3 than naphthenes of about the same range of b. p. Cracking apparently occurs chiefly at the heated surfaces, so that too rapid distn. must be prevented; slow and less intense firing of the still greatly diminishes the percentage of olefins in the gasoline produced, although the yield of gasoline is much increased. The amt. of gas evolved and coke deposited increases very rapidly as the working pressure is increased beyond 100 lbs., varying with app. and distn. rates. If the heating surfaces are vertical, the amt. of coke deposited is not more than 0.2 as much as is obtained under the same conditions but with the heating surfaces horizontal. The claims of Burton to the effect that condensing the vapors under 75 lbs. pressure yields gasoline of satd. character, whereas releasing the vapors close to the still and condensing them at atm. pressure yields gasoline of too unsatd. character for industrial use, could not be confirmed. By distg. Oklahoma reduced oil under 80 lbs., practically identical products were obtained by both methods. Examn. of the gasoline made from Oklahoma reduced oil, 30° B $\acute{e}$., by distg. under 100 lbs., shows that in addition to approx. 8% of C_6H_6 , toluene, and *m*-xylene, the material appears to consist chiefly of normal paraffin hydrocarbons. B. believes that the occurrence of C_6H_6 , toluene, and xylene in the gasoline made by cracking heavy oils under the conditions described is to be explained by the splitting off or "cracking" of high-boiling complex hydrocarbons, containing the phenyl radical. Exptl. results on the Oklahoma reduced oil and on synthetic phenylparaffin are given in detail to support this view. In the course of the work on the distn. of heavy petroleum oils, B. operated up to working pressures of 450 lbs. per sq. in. Tables, curves, and details are given.

F. W. SMITH.

Chemical-technical investigation of the Matitza asphalt. C. NICOLESCO-OTTIN. *Ann. sci. Univ. Jassy* 9, 138-68(1915); *Chem. Zentr.* 1915, II, 504.—The asphalt is dark colored, dull, compact, and has a peculiar odor. The mass is brittle, and has an oily feel; the fracture shows traces of cryst. structure. The material is apparently bituminous; it softens on warming. The $CHCl_3$ ext. averaged 29.91%. Fractional extrn. with alc., then ether, and finally $CHCl_3$ gave (same sequence): 6.5%, 10.3%, 12.3% (=29.2% sol. bitumen). Petroleum ether at 150° extd. 28.35%. Results are shown in tables:

Bitumen.	% C.	% H.	% S.	% N.	% O.	I no.	Sapon. no.
Extd. with alc.....	82.75	10.66	0.57	0.94	5.08	19.15	85.17
Extd. with ether.....	82.52	10.57	0.82	0.88	5.21	17.28	59.03
Extd. with $CHCl_3$	79.85	10.34	0.93	0.86	8.02	25.03	107.60
$CHCl_3$ ext.....	81.12	10.45	0.79	0.88	6.76	19.62	86.36

Bitumen.	Acidity.			D.	Softening point.	Drop point.
	Ether.	CHCl ₃ .	Total.			
Extd. with alc.....	13.03	1.03	14.06	1.0100	30-35°	42-45°
Extd. with ether.....	21.57	4.35	25.92	1.0715	89-92	110-115
Extd. with CHCl ₃	17.44	3.10	20.57	1.1520	155	170-180
CHCl ₃ ext.....	17.41	3.60	21.01	1.0851	78-81	97-99

The C and H content is dependent upon the solubility; the readily sol. portions contained the greatest amts. of C and H. The S and O content increased with diminished solubility. The product is characterized by its low S content. The I no. indicates that the content of unsatd. hydrocarbons must be low. The const. indicate a first class bitumen.

F. W. SMITHER.

Determination of water in mineral greases (CAMPO) 7.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Advances in paper testing in the years 1913-1914. W. HERZBERG. *Papier Ztg.* 40, 1708-10, 1728-9, 1744-6, 1765-6(1915).—A review. V. NUNEZ.

Paper testing. PAUL WAGNER. *Wochenbl. Papierfabr.* 46, 235-8, 425-8, 621-3, 659-60(1915).—A review of thesis work done at the Kgl. sächs. tech. Hochschule, Dresden. The following subjects are dealt with: influence of animal sizing on the strength of paper; viscose sizing; influence of high temps. on sizing; influence of high temps. on strength of various grades of paper; influence on paper of disinfection by steam, hot dry air, and hot moist air; discoloration of paper with age; influence of aging on strength of papers containing chem. wood pulp as compared to all-rag papers; influence of moisture content of papers on their strength; influence of compn., sizing and ash content on strength of papers made in the same manner; influence of width and breadth of strip, machine direction, and rapidity of applying stress on the results of paper strength testing.

V. NUNEZ.

Testing pulps for moisture. D. V. MCSWENEY. *Paper* 17, No. 11, 16-8(1915).—Well considered suggestions for testing pulp for shipment. V. NUNEZ.

Determination of permeability of paper to air. W. HERZBERG. *Papier-Ztg.* 40, 1656(1915).—An app. for detg. the porosity of paper is described in which air is drawn through a given area of paper by means of a suction pump connected with a pressure regulator. Pressure is measured by water manometers and vol. of air by a gasometer. The app. makes possible the use of const. pressures and use of air of any desired temp. and humidity. At 65% humidity and a pressure of 10 cm. water, blotting paper transmitted 64.3 l. air in 5 min., print-paper 2.9 l., pergamin 0.1 l. and parchment 0.1 l.

V. NUNEZ.

Paper fiber analysis. MAX CLINE. *Paper* 17, No. 3, 19-21(1915); *Chem. Eng.* 22, 164-6(1915).—Microscopic estn. of the ground-wood pulp content of paper, while rapid and convenient, is even approx. accurate only in skilled hands and under carefully controlled conditions. Much greater accuracy is obtained by chem. methods, e. g., phloroglucinol absorption or detn. of cellulose content.

V. NUNEZ.

Beating test for paper-making fibers. E. SUTERMEISTER. *Paper* 17, No. 9, 11-8(1915).—Treatment of pulp for 1 hr. in a small ball mill is a test of great practical value for detg. the strength of sheet to be expected on beating and to detect differences in strength

and quality of the pulp under test. The fiber so treated is made up into sheets on hand molds and their strength detd. by the Ashcroft tester which is more suitable than the Mullen tester for this purpose. The temp. at which the beating is conducted affects the results to some extent, high temps. producing weaker sheets. Atm. humidity has some effect on the results obtained by the Ashcroft tester, the max. strength figures for the fibers tested being obtained between 30% and 50% relative humidity. Of major importance is the moisture control of the pulps taken for test. Wet pulp, i. e., lap pulp which has never been dried, gives the strongest sheets both before and after beating; air-dried pulp gives weaker sheets; and steam-dried pulp still weaker. This loss in strength is progressive as the pulp loses moisture but is most marked when the moisture content becomes less than 10%. For reliable results from this beating test therefore it appears necessary to bring the pulps to a const. moisture content before testing. Soaking in water for an extended period was of some benefit in restoring strength to air-dried pulp and bleaching effected complete restoration of the Ashcroft strength. The strength of the sheets increases with time of beating at least up to 8 hrs. (time limit of tests) and shrinkage on drying also increases. No const. relation appears between percent. shrinkage and strength of sheet. The ball-mill test is applicable to sulfite and sulfate pulps, but ground-wood and soda-poplar pulps yield rather indefinite results.

V. NUNEZ.

Chemical analysis of wood-pulps. BJARNE JOHNSEN. *Pulp Paper Mag. Can.* 13, 600(1915).—Brief review of J.'s researches in the chemistry of cellulose, dealing particularly with estn. of lignin by splitting off the methoxyl group by means of concd. HI, of furfural-yielding constituents by heating with HCl, and of cellulose. In detn. of cellulose hydrolysis of the pentosans is accomplished by König and by Tollens by use of mineral acid. J. finds that these attack the cellulose and advocates use of AcOH for hydrolysis followed by oxidation with NaNO_2 and H_2SO_4 . This modification is, however, not applicable to wood.

Improved titration method for the analysis of sulfite cooking acids. R. DIECKMANN. *Wochenbl. Papierfabr.* 46, 1764(1915).—The method of Sander (*C. A.* 8, 2132) and that of Feld (*C. A.* 7, 2732) rest on the oxidation of the SO_2 to SO_3 by I, setting free I corresponding to the free SO_2 by addition of KI and KIO_3 , and titration by $\text{Na}_2\text{S}_2\text{O}_4$. D. finds the use of KI unnecessary, 5 cc. of 3% KIO_3 soln. only being required for each cc. of cooking acid taken for analysis.

V. NUNEZ.

Specific gravity of wood and pulp. ERICH RICHTER. *Wochenbl. Papierfabr.* 46, 1529-33(1915).—Balsam wood (*Abies fraseri*) of 12.5 to 21.5 cm. diam. gave the following av. values: (a) moisture 49.4%, (b) dimensional shrinkage on drying 8.2%, (c) d. wet 0.688, (d) d. dry 0.373. Spruce (*Picea nigra*) gave (a) 29.4%, (b) 10.0%, (c) 0.583, (d) 0.436. Sp. gr. in EtOH of various sulfite pulps was detd. by pycnometer methods. D. varied from 1.408 to 1.634 and was in general highest in those pulps of high ash and lignin content although no definite relation existed in this regard. D. of pure cellulose by the same method was 1.583 and of black spruce, white spruce and balsam (heart-wood), 1.512, 1.517 and 1.402, resp., showing that the d. of the non-cellulosic constituents of wood must be considerably less than that of the cellulose. Variation in d. from heart to outside of sticks of wood was slight but noteworthy.

Manufacture of filter paper in France. M. DURIEUX. *Ann. fals.* Aug., 1915; *Schweiz. Apoth. Ztg.* 53, 614-5 (1915).—The old hand or vat process still in use at Ambert, and the modern machine process are described. "Ashless" 9 cm. filter papers leaving 0.000125 and 0.00015 g. of ash are at present obtained, also hardened papers retaining cold-pptd. BaSO₄. S. WALDBOTT.

Removal of rosin from chemical wood-pulp. A. D. G. KUHN. *Papier-Fabr.* 13, 725-30, 744-6 (1915).—Well cooked sulfite pulp made from properly prepd. wood will contain about 44% of the rosin originally present in the wood. Washing the pulp with hot water will largely remove this rosin. The main conditions for effective washing are (1) the entire bottom and preferably also part of the sides of the blow pit to consist of drain plates, and (2) large inlets and outlets for wash water. V. NUNEZ.

Neutralization and fermentation of sulfite waste liquor. ERIK OERMAN. *Papier-Fabr.* 13, 534-8, 553-5 (1915).—General. V. NUNEZ.

Length of fiber of the southern pine. C. BEADLE AND H. P. STEVENS. *Chem. News* 112, 225-6 (1915).—Samples of pulp made from *Pinus palustris* from Florida were found to have an av. fiber length of 5.278 mm. This is exceptional even for long-leaf pine. V. NUNEZ.

Yield of paper on green stem of banana. C. BEADLE AND H. P. STEVENS. *Chem. News* 112, 235 (1915).—The fact that about 132 tons of green banana stem are required, to make 1 ton of paper, would make necessary some mechanical sepn. of fiber on the field if this fiber were to be exploited commercially. V. NUNEZ.

Choice of paper for half-tone engravings. H. P. CARRUTH. *Paper* 17, No. 5 11 (1915).—Discussion of the relation of the kind and finish of the paper and the kind of ink, to the half-tone printing properties, illustrated by excellent photomicrographs. V. NUNEZ.

White wood-pulp board. E. KIRCHNER. *Wochenbl. Papierfabr.* 46, 1492-4 (1915).—Calendering decreased the av. bulk of pulp board from three mills 28%, and increased the breaking length 16.7% and the stretch 14.1%. The length and appearance of the fibers and the slowness of the stock of these boards considered in relation to their respective strengths confirms K. in his belief that most mills grind wood unnecessarily fine for this class of product. V. NUNEZ.

Highly polished celluloid surfaces. KRAEMER & VAN ELSBERG. *Ger.*, 285,349, Oct. 31, 1912. The celluloid is polished by pressing against highly polished metal surfaces.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Action of alkalis on trinitrotoluene. M. COPISAROW. *Chem. News* 112, 283-4 (1915).—From the results obtained by many investigators using trinitrobenzene, *p*-nitrotoluene and its numerous *o*-substitution products, including trinitrotoluene, the following conclusions are reached: (1) The reactive sensitiveness of nitro groups towards alkalis increases with their accumulation in the mol. (2) The sensitiveness and number of chem. changes is greatly augmented by the presence of an alkyl radical

in the *p*-position, facilitating probably the formation of nitric acids ($R.NO(OH)_2$). (3) The reactivity of the mol. is very much increased by the introduction of electro-negative groups in the *o*-position to the alkyl radical. Alkalies produce addition, substitution and condensation compds. Alkalies and alk. compds. produce red colorations in α -trinitrotoluene. C. found that when 5 cc. of a satd. soln. of KOH in MeOH (about 33% KOH) cooled in solid CO_2 -ether mixt. are added to 0.166 g. of pure 2,4,6-trinitrotoluene dissolved in 1 cc. of pyridine and 5 cc. MeOH, the latter soln. being kept in solid CO_2 -ether mixt., the color change took place at a temp. as low as -65° . The products of reaction of alkalies with trinitrotoluene are highly explosive. Dupré found the addition of a little KOH caused trinitrotoluene to explode when heated to 160° .
CHARLES E. MUNROE.

Hazards in handling gasoline. GEORGE A. BURRELL. *Bur. Mines, Tech. Paper* 127, 11 pp. (1915).—At ordinary temps. air will hold 5% vapor of cleaner's naphtha, 11% 64° Bé. gasoline, 15% 69° Bé. gasoline, and 28% 73° Bé. gasoline. Because gasoline vapor is 3 times heavier than air the atm. of a confined space has the largest proportion of gasoline vapor at the bottom. The limits of explosibility for gasoline vapor-air mixts. are 1.4 to 6% of the former, although dangerous flashes may be produced in mixts. containing less and more than these percentages of gasoline vapor. One gallon of gasoline can, under ideal conditions, form an explosive mixt. with 2100 cu. ft. of air. Burning liquids are extinguished by forming a blanket of gas or solid material over them to cut off the supply of air, or by diluting them with water. As gasoline is not miscible with water the latter serves but to scatter the burning gasoline; therefore blankets of sawdust or frothy mixts. are used. In some large plants gasoline is stored under pressure of N or CO_2 gas. In others the tanks are kept so filled by aid of water that there is no space for a vapor-air mixt. to form. B. claims that the mixt. may be ignited by sparks.

Indigo and hydron blue in apparatus-dyeing. ERNST JENTSCH. Copenhagen. *Färber-Ztg.* 26, 202-3 (1915).—A suitable light blue (pearl-blue) which can be obtained on hanks of yarn in a Zn dust-lime vat only with two passages can be produced in a Thiess app. on cops and similar forms with one passage. The stock-soln. (for 1500-1600 lbs. of cops) is made from $2-2\frac{1}{2}$ kg. of indigo MLB powder, $6-7\frac{1}{2}$ l. 40° Bé. NaOH soln., $2\frac{1}{2}$ kg. of hyposulfite, and H_2O to make a vol. of 50 l. Into

the vat of the app. are placed $2\frac{1}{2}$ l. of 50% Turkey red oil, $\frac{3}{4}$ l. 40° B $\acute{e}$. NaOH soln. and 1 kg. of hyposulfite and sufficient H_2O to give a vol. of 1000 l. After circulating for 5 min., 6 l. of the stock-soln. is added through a sieve. Smaller quantities are added for subsequent parts of the lot. The liquor is circulated for $\frac{1}{2}$ to $\frac{3}{4}$ hr. Hydron blues G and R can be used also, and for some shades $1\frac{1}{2}$ – $1\frac{3}{4}$ kg. of hydron blue R can be used in place of 4 kg. of indigo. This effects economy. The dyeings are satisfactory, and less supervision of the process is necessary. Hydron blue G is suitable for a light pearl-blue, the bath being nearly exhausted. Without Turkey red oil, the dye is not distributed well in the bath, and the deposit is largely superficial. A concd. stock soln. cannot, however, be prepd. An abundance of NaOH must be used in order to utilize the dye thoroughly. The baths may be used subsequently for lighter shades.

W. F. FARAGHER.

The action of assistants in monochrome dyeing. A. GROSS. *Färber-Ztg.* 26, 185–6(1915).—Rapid dyeing methods for wool have become necessary and for this reason the use of the monochrome process has been favored. In $2\text{--}2\frac{1}{4}$ hrs. a lot of field-gray can be turned out which is entirely satisfactory in regard to fastness. It was formerly impossible, however, to guarantee an exact match in shade for different lots, as matching is more difficult with this process than with the after-shaded acid-process. It is known also that different qualities of wool when dyed together in a lot always differ in shade. This was of less importance for the user than having fugitive dyeings. By regulating conditions, satisfactory matches can now be obtained without shading. The use of assistants is important. Glauber's salt and $MgSO_4$ are essential with some dyes and in no case are they detrimental. They act also as good bath-purifiers. When replacing one of these by the other in producing light shades, they should be used in quantities proportional to the molar wts., in order that the concns. of SO_4^{--} may be equal, and the shade obtained be thereby maintained.

W. F. FARAGHER.

Rapid dyeing methods. G. TAGLIANI. *Färber-Ztg.* 26, 225–8(1915).—Piece dyeing of cotton goods is generally done by one of two methods: jig-dyeing for fabrics which require handling in open width and under tension, and reel-vat-dyeing for fabrics which can be handled as hanks. Other processes are being used, as, e. g., the continuous vat and so-called foulards. The latter are, however, less frequently used. Until recently, foulard-dyeing had found practical use only when bright and medium shades were desired and when no great demands on levelness, penetration and fastness were made. The process is, however, cheaper than the other methods. It allows all of the after-treatments, and insures good production. The method is essentially one of short immersion of the fabrics, followed by squeezing and drying in warm air. For dark shades, the proper amt. of dye soln. must be left in the fabrics, and the soln. must be taken up quickly and evenly. For this reason, the baths consist of a concd. dye soln. nearly free from salts and contain some dextrin and sol. oil. A short exposure to the air should be given before the piece passes onto the copper drying drum. By supplementing with a small steaming app., washing app., and chroming or acid vats, vat dyes may be used.

W. F. FARAGHER.

Replacing Turkey red oils from castor oil by sulfonated products from the free acids of this oil and from oleic acid. FRANZ ERBAN. *Färber-Ztg.* 26, 186–91 (1915).—The castor oil fatty acids were prepd. by sapon. with NaOH and subsequent treatment with H_2SO_4 . In heating the fatty acids to sep. them from the acid liquor and to dry them (100°) some polymerization is effected as is shown by the acid number (169 instead of 188). The mixt. contained 82.3% free mixed fatty acids, 15.3%

diricinoleic acid, 1.8% unsaponified oil and 0.6% water and impurities. H_2SO_4 (66° Bé.) was used in 3 proportions, namely, 15, 25 and 35% of the wt. of the fatty acid. Partial neutralization was obtained by the use of NaOH solns. The resulting products were in all cases inferior in stability and emulsifying power to the corresponding products made from neutral oil. In the case of the products with the higher percentages of combined S, the low percentage oils could be had only in the form of rather unstable emulsions. The products from com. oleic acid (red oil) were still less satisfactory. For some purposes, however, the stability and emulsifying power of these products are sufficient to justify their use. Directions in full are given for prepg. the various products and for using them in the production of various dyeings.

American cotton industry as seen by the industrial chemist. F. DANNERTH. Newark. *J. Ind. Eng. Chem.* 8, 75-8(1916).—In this address a strong plea is made for more chemical control and research work in all lines of the cotton industry.

L. W. RIGGS.

The Cross-Bevan jute-reaction and its use on raw cotton. R. HALLER. Traun. *Färber-Ztg.* 26, 157-9, 173-6(1915).—Upon mixing equal vols. of 0.1 N FeCl_3 and 0.1 N $\text{K}_3\text{Fe}(\text{CN})_6$ solns., a clear, brown soln. is obtained. This reagent is, however, not stable, and there soon appears on the surface a blue opalescent skin and simultaneously the soln. deposits a dark green ppt., which according to Messner (*Z. anorg. Chem.* 9, 126(1895)) consists of Prussian green, $\text{Fe}_3(\text{CN})_{24}$. In the freshly prepd. soln., jute soon acquires a dark blue color, with no trace of green, showing that the deposit on the jute is not Prussian green. C. and B. proved it to be Prussian blue. Since reduction of ferricyanide does not occur on standing, jute must contain some reducing substance. Pure cellulose and lignocellulose do not react, while certain varieties of raw cotton give a positive reaction. C. and B. showed that the addition of an oxidizing agent to the reagent does not prevent the reaction. Raw khaki-cotton (*Gossypium hirsutum* var. *religiosa* Watt) soon becomes blue-black, and *Gossypium nanking* var. *Himalayana* Watt (gray in color) acquires a slightly less intense color, which has a decidedly green cast. The whitest, purest of raw cotton, *Gossypium barbadense* Tiun (sea island) is colored a bright yellowish green. In the case of *religiosa* Watt the ppt. is Prussian blue. The fibers are colored homogeneously, as is shown by the microscope. Treatment with Schweizer's reagent reveals that only the outer cuticular layers contain ppt. By isolating the two brownish yellow natural coloring matters of cotton and cotton-wax, H. showed that each is able to ppt. Prussian blue from the reagent. The dyes which were recovered were altered, showing that the originals had undergone chem. change. C. and B. attributed the reaction to aldehydes. Hydrocellulose and oxycellulose give negative reactions although they are reducing agents and it follows that certain groups are essential. The freshly prepd. soln. shows sub-microns in dark-field illumination. These are very numerous and have a peach-blossom color. The separate solns. are optically empty. Soon larger aggregates without motion are observed, although macroscopically the soln. has not changed. Presumably this disperse substance is a ferric ferricyanide. If the brown soln. is placed in Schleicher-Schüll dialyzing thimbles, large quantities of $\text{K}_3\text{Fe}(\text{CN})_6$ pass through at first, together with HCl. The membrane soon becomes blue and a small blue ppt. is formed on the inside of the thimble. If the dialysis is continued until no more ferri-

cyanide passes through, and the contents of the thimble are filtered, a pale green filtrate is obtained which contains ferricyanide (shown by FeSO_4), but which gives no test for FeCl_3 . No FeCl_3 was found in the outer liquid at any time. Also no $\text{Fe}(\text{OH})_3$ can be present in colloidal soln., as even traces of ferricyanide ppt. this colloid. The filtrate, in dark-field illumination, shows large numbers of silvery mobile particles which are highly disperse. Even strong NaCl soln. does not flocculate this colloidal soln., which thus has an emulsoid character. Similar colloidal solns. are obtained by adding $\text{Na}_2\text{S}_2\text{O}_4$ in quantities insufficient for complete reduction of the reagent. A dark blue soln. results, which contains, presumably, colloidal Turnbull's blue and Prussian blue. Electrolytes do not flocculate this soln. (cf. Eibner and Gerstacker, *C. A.* 7, 2313). The pale green filtrate from the dialyzed jute reagent has a greenish luster—almost a fluorescence. Disperse blue substances usually appear violet-copper-red. The filtrate does not color jute, but does so weakly if a little FeCl_3 is added. The latter is apparently necessary for the reaction, as addition of HCl is without effect. By dialyzing a soln. of FeCl_3 in the presence of aniline, a colloidal soln. of $\text{Fe}(\text{OH})_3$ is obtained. When the aniline is added, its odor disappears, and a brown soln. similar in appearance to the jute reagent is formed. CaCO_3 and BaCO_3 do not behave similarly, as they adsorb $\text{Fe}(\text{OH})_3$. Addition of $\text{Fe}(\text{CN})_6^{3-}$ to the aniline-containing soln. gives a ppt. of Prussian blue. Other amines and phenols act similarly. However, amines and phenols which contain a nitro group do not give the reaction. H. concludes that the substances in jute and raw cotton contain NH_2 and OH groups. Treating jute with NaNO_2 to eliminate NH_2 groups, he finds that it still reacts, and concludes that OH groups are present. When jute is added to the reagent, the latter is imbibed freely. The reduction of the ferricyanide by the incrusting substances of the jute follows and the ppt. is formed in the fibers. This agrees with an observation made by Schwalbe ("*Zellulose*," p. 375, footnote) that only a weak color results when the jute is first immersed in the FeCl_3 and then in the $\text{K}_3\text{Fe}(\text{CN})_6$, since the color should be more intense when the two solns. are imbibed together. Simultaneously the ferric ferricyanide is adsorbed and the reduction follows. The mechanism of the process is therefore that of substantive dyeing.

W. F. FARAGHER.

Determination of the breaking strength of yarns and fabrics made from animal fibers. ERNST KRAUS. *Färber-Ztg.* 26, 232-3(1915).—The ordinary dynamometric tests giving breaking strength and elongation do not suffice to enable one to judge of the value of wool and silk materials. The considerable elasticity of these fibers is one of their most important properties. Within the elastic limit, the elongation is temporary and only when the elastic limit is passed, does the elongation become permanent. The simple detns. of max. elongation and breaking strength do not characterize wool. App. showing the elongation as a function of the applied load, in the form of a curve, are essential, as two samples may show the same max. elongation and breaking strength, and still be unequally valuable. Such an app. is that of Hartig. A 50 cm. test piece is used, and the app. is constructed for max. loads of 10, 20, 30, 40 and 50 kg. The cost is 850 M.

W. F. FARAGHER.

Water proofing military fabrics. H. POMERANZ. *Färber-Ztg.* 26, 171-3(1915).—Although the military authorities specify the nature of the dyes and the methods of dyeing, until recently they have not issued directions for the no less important matter of waterproofing and for the detn. of the degree of waterproofing obtained and the safety of the process for the fabrics. The recent requirement that the fabric shall withstand for 24 hrs. the action of a water column covering 50 sq. cm. and having a height of 75 mm. without allowing a drop of water to pass, is unsatisfactory. This degree of waterproofing can be reached by almost any of the processes in use. It is

important to det. how the fabric behaves after it has undergone the above test. If it begins to allow water to pass after 24 hrs., it frequently happens that the property of waterproofing is lost. Such waterproofing is illusory, and the fabrics will surely fail in field-use. Substances which render fabrics waterproof are not always insol. in water. Some swell in water and nearly all undergo some change. The desirable property therefore tends to disappear as the fabrics are continually subjected in service to the action of water. The above test should therefore be repeated several times. No material should be used which can weaken the fibers, and none the presence of which is unpleasant or unhygienic. The military department now forbids the presence of free acid and of alum or $\text{Al}_2(\text{SO}_4)_3$. The tests given are the action on litmus paper and the use of BaCl_2 . On the other hand, they recommend Al acetate and Al formate, fats, paraffin, etc. It is questionable whether the Al acetate mentioned is suitable, since on heating it passes into sol. basic compds. The mixed sulfate-acetate which is used sometimes as a mordant, should be preferable, since on heating it forms difficulty sol. colloidal $\text{Al}(\text{OH})_3$, free from acid. The product must be made sufficiently basic to insure the deposition of colloidal $\text{Al}(\text{OH})_3$ at 60–65°. There have recently been put on the market soaps which may be added to solns. containing Al^{+++} without the formation of a ppt. of Al soap. The soap removes the acidity of the soln., thus satisfying the requirements of the authorities. No sol. compds. of Ca should be present in the soln.

W. F. FARAGHER.

Waterproofing military fabrics. Reply to H. Pomeranz. C. BOCHTER. *Färber-Ztg.* 26, 214–6(1915).—Polemical (cf. preceding abstract). Repeating the water column test does not insure that a fabric which passes the test will preserve its waterproof character for a long time under service conditions. It is natural, however, that a fabric which withstands the test several times will be superior in use to one which fails on the second trial. B. proposes that the test-piece be crumpled while moist before drying after each test or that it be laid in small folds and allowed to dry thus. The tests are then to be repeated after intervals of 24 hrs. Usually a single repetition is sufficient, although if there is doubt, further tests should be made. Both Al acetate and Al formate are preferable to the mixed Al acetate-sulfate proposed by P. Waterproofing does not depend upon the deposition of a colloidal, acid-free $\text{Al}(\text{OH})_3$ by heating to 60–65°. The object of the heating is to fix the basic Al compds. upon the fabrics, so that they may be subsequently converted into Al soaps. For complete decompn. of the Al compds., thorough drying must follow the immersion in the boiling soap soln. The conversion of the Al compds. into $\text{Al}(\text{OH})_3$ would therefore be undesirable, as no Al soap could be produced. Moreover, the $\text{Al}(\text{OH})_3$ becomes hard and horn-like in time, and is then incapable of forming a continuous, elastic coating. Since the military fabrics are mostly dyed with S dyes, the use of H_2SO_4 even in the form of its salts is to be avoided. $\text{Al}(\text{OH})_3$ deposited on the fibers would be less readily attacked than the fibers. It is well known that it is difficult to wash out impurities in the presence of colloids and water-repellant substances, and it is therefore wise, when such substances are present, to avoid the use of H_2SO_4 . A satisfactory process devised by B. is as follows: Impregnate the fabrics in a double padding-machine with 4–6° Bé. Al acetate and then dry carefully in a hot-flue or dry-room at 45°. On a similar machine, treat the dried fabric in the following soln.: 25 g. grained soap, 5 g. rosin and 2 g. soda per l., or 15 g. dry, pure Na stearate, 5 g. rosin, and 2 g. soda per l. The addition of paraffin or stearin increases the effect. The bath should be as hot as possible. A second passage through the Al acetate after drying the Al soap is advisable. The fabrics should now be dried at a high temp. The frequently used process which is the reverse of B.'s gives inferior results and should be abandoned.

W. F. FARAGHER.

Waterproofing military fabrics. Remarks on Bochter's criticism. H. POMERANZ. *Färber-Ztg.* 26, 247-8(1915).—Polemical (cf. preceding abstracts). W. F. F.

Way to overcome aniline color shortage (KOMP) 23.

Printing in fast colors. BADISCHE. Ger., 284,855, Sept. 25, 1912. Addition to 281,859 (C. A. 9, 2154). Instead of fixing by steaming, as in the parent specification, fixing can be accomplished by treating the print with alk. agents. The resulting prints are similar in shades and properties to those obtained by the principal process. E. g., a print is made with a color containing 200 g. of a soln. prepd. from 20 g. Na hexahydroxyanthraquinonedisulfonate and 40 g. of fluorochrome, together with 40 g. HCOOH, 500 g. HOAc-starch-tragacanth thickening, and 260 g. H₂O. After drying, the print is treated for 1-2 mins. with a 3% soda soln., rinsed, and finished in the usual manner. Blue-green shades, very fast to washing and light, are obtained. The fixation can be effected also with NH₃ in soln. or as vapor.

Treating wool-scouring liquors. W. G. ABBOTT. Brit., 18,736, Aug. 17, 1914. Wool-scouring and like liquors are treated to sep. grease, etc., by heating under pressure until light greases rise to the surface, heavy greases settle to the bottom, and the intermediate liquor is clear. The liquor is heated in a closed vessel by a steam coil to about 165° until a sample of the liquor in a test glass suitably connected to the vessel, becomes clear by settlement of the grease on standing. The liquor is allowed to cool. The light grease, the clear liquor, and the heavy grease are removed sep.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

An electrically conducting paint. M. JAMES. *Elec. World* 67, 51(1916).—Two methods may be used: (1) treatment of a freshly bronze-painted surface with concd. HCl; (2) application of a paint that has been made to conduct by mixing with HCl. Exposure to HCl fumes also gives a like result. Although the entire film becomes conducting, the cond. varies greatly from point to point. The second method is carried out as follows: Bronze powder is mixed with amyl acetate soln., concd. HCl added and the whole stirred till pasty. The HCl is then washed out with H₂O, the paste decanted and mixed with Me alc. until suspension is obtained. The alc. is then poured off and more amyl acetate soln. added to get a good paint. The paint should be applied fresh. A soln. containing 2 parts amyl acetate to one of acetone and 5% celluloid yielded a paint of good covering quality and a surface resistance of 0.1 ohm per sq. cm. for 0.05 mm. thickness. The resistivity increases with time. A film on glass kept in the dark increased 50% in 4 mos. and in sunlight 200%. The presence of varnishes, shellacs or gums leads to the corrosion the metallic particles and should be avoided. W. E. RUDER.

Determination of the covering power of paints. H. K. VAN VLOTEN. *Chem. Weekblad* 12, 1077-8(1915).—On the rough side of a glass plate ground on one side, measuring 25 cm. by as many times 15 cm. as there are paints to be examd. at one time, is pasted a paper sheet with equally distant rectangular openings 20 × 10 cm. Small quantities of the different paints are mixed with a previously detd. percentage

of unboiled linseed oil. The glass plate is placed with the paper side down on the balance and equal quantities of the different paints weighed out on the uncovered sections. The paint is then spread out so that equal surfaces are covered with equal amounts of paint. The glass plate is placed in an inclined position, so that part of the paint flows down towards the lower edge but remains on the original surface. The wedge-shaped layer of paint is allowed to dry. A black strip on the opposite side of the glass shows the relative transparency of the different paints. J. V. F.

Polymerization of Chinese wood oil. C. L. SCHUMANN. *J. Ind. Eng. Chem.* 8, 5-15 (1916).—From his expts. S. concludes that the polymerization of Chinese wood oil is analogous to that of linseed oil, and takes place through the dissolution of one unsatd. linkage in each elaeomargaric chain, forming a triglyceride composed of dimolecular fatty acids. The formation of the gel is due to an insol. colloidal mass containing mol. complexes. The polymerization is "mesomorphic." The intermediate product is sol. in ordinary org. solvents, except very light petroleum ether, as well as in unchanged wood oil and rosin. The % of polymerized triglyceride in gels of the same apparent consistency is not necessarily the same. Elaeomargaric acid will cryst. from a dil. EtOH soln. at a temp. of 0°, while the acids from the polymerized triglyceride remain sol. If Chinese wood oil is rapidly heated to 350° it will polymerize, but the decompn. products will prevent the formation of the gel. Chinese wood oil polymerizes more rapidly than linseed oil; CaO, PbO and oxidation products act as catalysts accelerating the polymerization. The course of polymerization can be followed by the I value. Dissolving the gel in rosin or continually heating it above 250° constitutes a reformation of the sol. intermediate product. The darkening of rosin-Chinese wood oil mixts. is due to oxidation and may be avoided by the exclusion of air during heating. The pure polymerized product of Chinese wood oil dries very slowly.

E. W. BOUGHTON.

Boiled oil. W. FAHRION. *Chem. Rev. Fett-Harz-Ind.* 22, 110-2 (1915).—A semi-popular article which defines the meaning of "boiled oil" (linseed oil which has up to 2% metallic oxides incorporated for the purpose of increasing its drying speed), linoleate, resinate, oxide-driers, etc., and which repeats P. Muhle's proposition of distinguishing 5 classes of boiled oils: (1) Plain boiled oil (Firniss), drying oils which have their driers dissolved below 150°, (2) boiled oil (gekochter Firnis), temp. at least 200°, (3) blown oil (geblasenes Öl), (4) blown and boiled oil (geblasenes und gekochtes Öl) (5) siccativated oil, containing at most 5% drier and prepd. cold. P. E.

A modern jappanning plant (TURNBULL) 4.

Anti-fouling paint. B. MALENKOVIC. *Ger.*, 285,261, Dec. 23, 1913. The products contain ethers or esters of the naphthols or their homologs or derivs., especially the hydroxy and amino derivs. of these compds., not, however, nitro derivs. The aromatic ethers and esters have been found to exert a repelling action on the lower animals merely by the odor which is commonly present. Further action is, in sequence, exciting, stupefying, paralyzing, and finally lethal. These ethers and esters act more quickly in proportion to their volatility. Too great volatility, nevertheless, is detrimental to their practical use. Less volatile and more active are the ethers and esters of naphthalene and its homologs and of naphthols and their homologs, *e. g.*, naphthyl methyl ether, naphthyl isoamyl ether, naphthyl acetate, naphthyl ether, dinaphthylene oxide. All these substances may be converted into powerful poisons for lower plants

if salt-forming groups are introduced into the atomic complex, whereby H_2O likewise results. The salt-forming groups specified are OH , NH_2 , and NH . The group SO_3H is not suitable, since it neutralizes the action, also the group $COOH$ is not well suited, since it has a weakening effect. For ships' bottoms these substances are simply added to the pigment, but for painting wood, they are dissolved in oils or converted into salts and dissolved in H_2O . Sprays for plants are prepd. in the latter manner.

Oil and paint films. OEL & FARBFILM AKT.-GES. Brit., 18,889, Aug. 20, 1914. Oil and oil paint films are prepd. in the form of webs of any desired size by impregnating a strong, slightly glued paper with an alk. soln. such as water-glass soln. on one side, the other side being, if desired, varnished, and then spreading the oil or paint on the side that has been impregnated with water-glass. The alkali saponifies the oil so that, on drying, the film may be stripped off, and is sufficiently adhesive on its saponified side to adhere to any desired surface without additional adhesive. The films may be attached to fabrics, paper, wood, Fe, etc., to give a washable or water-proof surface for bags, packing material, wall coverings, clothing, etc. Cf. C. A. 9, 2319.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Annual review on fats, oils and waxes for 1914. W. HERBIG. Chemitz. *Chem. Rev. Fett-Harz-Ind.* 22, 17-9, 28-30, 38-40, 47-9, 57-60, 67-9, 80-1, 90-2, 99-101, 108-10(1915).—A comprehensive and critical annual review. P. ESCHER.

Manufacture of lanolin. B. LACH. *Seifensieder-Ztg.* 42, 929-31, 950-1(1915).—The amt. of wool fat in wool varies from 6 to 35%. It is recovered by extn. with a solvent or by washing with alkali carbonates and acidifying the soln., or the wash waters may be treated by alk. earth salts. In both cases the waters are filtered and the cake dried in the 1st case and acidified in the 2nd to decompose the soaps. If lanolin is to be made, the fatty acids are removed by pptn. with $Mg(OH)_2$ and the unsaponifiable matter extd. with CS_2 , benzine or trichloroethylene. The best solvent is acetone. In order to remove all saponifiable matter the above handling is repeated. The crude wool fat obtained from the wash waters is often distd., yielding, after pressing, wool fat, olein and stearin. The crude lanolin is purified by bleaching with fuller's earth.

E. SCHERUBEL.

Fish oil industry in Hokkaido. SEIICHI UENO. *J. Chem. Ind. Japan* 18, 798-808(1915).—Hokkaido is known as a famous fishery in Japan. The oils produced are classified by U. as follows: body oils: herring (*Clupea pallasii* C. & V.), sardine (*Sardinella melanosticta* T. & S.), flat fish (*Pleuronectidae*), kinkin oil (*Helicobnus marmoratus* C. & V.), sculpin oil (*Myoxocephalus*), menukedai oil (*Sebastolobus macrochir* Günther), kuromenuke oil (*Sebastes glaucus* Hilgendorf), suginouwo oil and sand eel oil. Liver oils: cod liver (*Pollachius brandti* Hilg.), sting ray oil (*Dasyatis akajei* M. & H.), ray oil (*Raja kenoei* M. & H.), suketo, tara oil (*Pollachius chalcogramma* Pall), shark oils (*Selachoidae*), calamary and cuttle fish and globe fish oil. Blubber oils: whale oils. Liquid waxes: sperm oils. Herring and liver oils are prepd. on a large scale. The body oils are inferior in quality and are used in the hardened oil industry. E. S.

Hardening of oils. SEIICHI UENO. *J. Chem. Ind. Japan* 8, 545-65(1915).—Discussion of the following subjects: Hydrogenation of sardine oil on a semi-industrial

scale. Examn. of the intermediate products of hydrogenation. Durability of the activity of Ni and revivification of spent catalyzer. Hydrogenation at low temps. Relation of the catalytic activity of Ni-kieselguhr catalyzer to the proportions of the Ni and its carrier. E. SCHERUBEL.

Fatty oil from rose seed (hagebutten). ARTHUR MEYER. *Apoth.-Ztg.* 30, 595 (1915).—Grape seed is also mentioned as a possible source of fatty oil. W. O. E.

Conservation of hot transformer oils through absence of air. P. M. GREMPER. *Seifensieder-Ztg.* 42, 936(1915).—It was found that when these oils are kept from contact with air they do not decompose. E. SCHERUBEL.

Modern toilet-soap manufacture. B. ZIENLE. *Seifensieder-Ztg.* 42, 949-50 (1915).—Discussion of necessary equipment. E. SCHERUBEL.

Soft soap from liquid linoxyn. H. GRIFF. *Seifensieder-Ztg.* 42, 929(1915).—A satisfactory Na and K soap was made from liquid linoxyn either half boiled or cold made. E. SCHERUBEL.

Replacing Turkey red oils from castor oil (ERBAN) 25. Relative digestibility and utilization of lard and hydrogenated vegetable oil (SMITH) 11E. Sulfonated oils (BUMCKE) 29.

Hydrogenation of oils. K. P. McELROY. U. S., 1,157,993, Oct. 26. Hydrogenation of oils such as cottonseed oil is effected by maintaining a body of mixed oil and catalyst in the chamber 1 heated by a steam coil 2 and circulating H from the upper to the lower part of the chamber by the blower 17 and pipes 18 and 19. The catalyst is used on a light carrier such

as petroleum coke so that it is readily kept in suspension in the oil. 7 is a H supply pipe. 14 is a vent for waste gas and 12 an entrainment chamber for sepg. liquid.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

A review of the progress of the sugar industry in 1914. V. VILLAVECCHIA AND G. ROSSI. *Ann. chim. applicata* 4, 270-84(1915). E. H.

Molasses formation from the standpoint of the phase rule. T. VAN DEN LINDEN. *Arch. Suikerind.* 23, 1033-50, 1389-1418(1915).—The system sugar-H₂O-non-sugar is discussed as though the non-sugars could be represented by a single component. Molasses is defined as a mixt. which is satd. not only with respect to sucrose but also with respect to at least one more substance. Ideal diagrams for this ternary

system are given and the influence of various factors on molasses formation is discussed in the light of these diagrams. On the assumption that no compds. are formed, the conclusions are: (1) For every mixt. of a given purity there is a definite Brix below which true molasses cannot be obtained after cooling and centrifuging. (2) If cooked to too high a Brix it may be dild. to the proper Brix without greatly changing the purity of the molasses. There are 2 possible cases depending on the position of the sugar-non-sugar eutectic line; (a) the purity decreases with the H_2O content, (b) it increases with increasing H_2O . (3) If dild. below the proper Brix, the purity will rise rapidly. (4) The lower the purity of a pan, the lower the Brix to which it should be boiled. (5) A pan of low purity may be dild. further than one of high purity if both were boiled to the same Brix. (6) The higher the Brix to which a pan is boiled, the higher should be the temp. of centrifuging. If (2a) holds, this is disadvantageous; if (2b), the reverse. (7) If (2a) holds, adding H_2O and cooling may sep. out sucrose and evapg. H_2O will have no effect; if (2b) holds, adding H_2O has no effect and evapg. H_2O seps. out sucrose. (8) If the non-sugars are largely inorg. the purity will be high (beet molasses). (9) If the non-sugar is chiefly invert the purity will be lower (cane molasses). (10) If the ratio glucose: ash is high the purity of the molasses will be low and *vice versa*. (11) Adding glucose to thick juice should lower the purity of the molasses [but see Claassen, *C. A.* 9, 975.—ABSTR.]. (12) Any substance of low m. p. which does not introduce other complications will have the same effect as glucose. On reviewing the same ground but with the assumption that compounds might be formed, there are no important changes in these conclusions. If molasses is considered, not as a eutectic but an exactly satd. soln. of sucrose, whether stable or metastable, it is necessary to det. the surface representing satd. sucrose solns. in the system sucrose-glucose-salt- H_2O . This can only be done very incompletely from data now available; and the most satisfactory progress is made from this point on by Geertig's molasses theory.

W. L. BADGER.

Molasses from the standpoint of the phase rule. A. SCHWEIZER. *Arch. Suiker-ind.* 23, 1054-6(1915); cf. preceding abstract.—Comment on van den Linden's article, and suggestions as to investigations which should be taken up to throw light on obscure points in the equil. diagrams.

W. L. BADGER.

Report on saccharine products. F. L. SHANNON. *J. Assoc. Official Agr. Chemists* 1, 472-80(1915).—This work consists of a study of the methods for the detection of artificial invert sugar in honey. Nine of the best tests were used and it was found that artificial invert sugar can readily be detected when it is present in amts. of 20% or over. When the amt. is only 5% some difficulty is experienced. The nature of the adulterant has something to do with the possibility of its detection as a 5% Herzfeld sirup was readily detected in a sample while the presence of 5% commercial invert sugar in a sample was considered doubtful. This is explained by the fact that the Herzfeld sirup was made by heating while the commercial invert sugar was no doubt made in the cold. Further work is recommended with Feder's aniline-HCl test and with the Fiehe test by allowing the color to develop 24 hrs., noting the color immediately after the addition of the reagent in the Hartman modification and changing the word "vigorously" to "gently" in the Bryan modification of this test.

A. GROSS.

The double polarization process applied to cane products and the variation of the constant to be applied. H. PELLER. *Intern. Sugar J.* 17, 558-60(1915); cf. *C. A.* 9, 3374.—P. does not believe that the double polarization process is inapplicable to cane juice which has been treated by lime at the b. p. and stated by Walker (*C. A.* 10, 127) to be due to the decompn. products of glucose, causing too low results. He expects

to show by previous experience and a series of expts. that the double polarization method is not at fault. Walker suggests that the const. be changed from 142.66 to 142.92. From the analysis of the pure sugars prep'd. by Walker, P. finds that the polarization should have been higher and concludes that the saccharimeter used by W. must have corresponded to 99.90 at the 100 point. The question of the correctness of a const. is a matter of individual treatment, variations in instruments and methods causing the usual differences suggested.

A. GROSS.

Contribution to the examination of cane sugar. T. v. FELLEBERG. *Mitt. Lebens. Hyg.* 6, 197-8(1915).—For the detn. of invert sugar in the presence of sucrose, dissolve 20 g. of the sugar in cold, recently boiled H_2O and dil. to 200 cc. Place 50 cc. in a porcelain dish and heat to boiling; add 50 cc. of Fehling soln., treated in the same way, to the sugar soln. which is covered and kept boiling for 2 min. Make a blank with 5 g. pure sucrose. The difference between the value for the blank and that for the sample is the invert sugar, termed by F. "organic impurities." The sample of sugar examined had a faint odor and taste of caramel with H_2O insol. of 0.11%, ash 0.02%, and invert sugar (organic impurities) 0.11%.

A. GROSS.

The determination of reducing sugar in the presence of sucrose. H. PELLER. *Ann. chim. anal.* 20, 169-75(1915); cf. *C. A.* 8, 1681, 2633; 9, 1699, 2463.—Saillard is wrong in saying that, while sucrose does not reduce Fehling soln., it influences the results. Sucrose reduces Fehling soln.; the reduction is greater the longer the boiling, the greater the amt. of sucrose, or the greater the alkalinity of the soln. Sucrose does not reduce Violette's soln. 10 g. sucrose boiled 10 min. by the new procedure of P. (*C. A.* 8, 1217) gave no reduction. Longer boiling gives reduction. The ordinary purification of sucrose does not free it from reducing sugars. Beet sugar, prep'd. by an alk. process and centrifuged, contains 0.03% ash, 0.04-0.05% org. matter, 0.06-0.08% H_2O , and gives no reaction for invert sugar, when tested by a process which will show the presence of 0.01%.

P. M. GIBSY.

The influence of the methods of juice purification on the production of molasses. J. S. DEHAAN. *Arch. Suikerind.* 23, 878-88(1915).—Results for 1914 from 9 carbonation factories (a) and 22 defecation-sulfitation factories (b) were recalcd. to give parts molasses of 87.4° Brix and 37.8 purity per 100 parts non-sugars in the raw juice. This gives for (a), max., 168; min., 110; av., 134; for (b), max., 181; min., 155; av., 166. The figure 168 for (a) comes from a plant which has always had a high figure for the amt. of molasses formed, perhaps from especially high alkali salts in its juices. Omitting this the max. for (a) is 142 and the av. 128.5. Calcns. are given which show that for conditions in Java the carbonation process results in a yield of 2.53% more marketable sugar. For 100 parts of non-sugar in the raw juice, the carbonation factories sent 73 parts, the defecation factories 90 parts, into the molasses. Non-sugars are obtained by calcn. from Brix and purity. A sample of raw juice was purified by different methods, and the change in sulfate ash detd. to check the removal of inorg. non-sugars. The raw juice had an ash of 1.66%. Defecated with 0.8% of 15° Bé. milk of lime, the ash increased 2.4%; double carbonation by the usual method, 10% of 20° Bé. milk of lime, a decrease of 26.3% ash; single carbonation, same liming, decrease of 25.8%; double carbonation, deHaan's method, 6% of 20° Bé. milk of lime, decrease of 24.6%; single carbonation, deHaan's method, decrease of 31.0%.

W. L. BADGER.

A study in the chemical control of cane sugar factories. NOEL DEER. *Intern. Sugar J.* 17, 514-6(1915); cf. *C. A.* 9, 3374.—D. strongly inclines towards the use of gravity purities. Abs. purities demand too much time and refractive detns. are not of sufficient delicacy for control work. The question of polarizations as opposed to sugar

% as a basis is discussed. As deductions drawn from a polarization basis are deceptive, a routine is given for the laboratory control of sirup, raw sugar, molasses and raw juice. The actual effect of clarification is shown to be 0.63 unit when sugar % is substituted for polarization which indicated a rise of 1.33 units. In estg. the economic limits of maceration an essential point is the purity, as upon this depends the proportion of sugar which can be extd. Last mill juices when valued on their gravity purity detd. at high dilns. show too low a value. If, however, the calcn. be based on a comparison of the mixed juices obtained under 2 systems of milling, the error due to decrease in gravity purity with diln. will tend to disappear. A. G.

The latest prescribed rules for chemical control in the cane sugar factories in Java. IV. H. C. PRINSEN-GEERLIGS. *Louisiana Planter* 55, 364-5 (1915).—Continuation of previous articles (cf. C. A. 9, 2990). Methods are given for the sampling and analysis of sirup, massecuites, green molasses, final molasses, and first and second sugars (molasses sugar). A. GROSS.

The Naudet diffusion process at the Toledo (Ohio) sugar factory. A. MUSY. *Sugar* 17, No. 12, 26-7 (1915).—Results indicate a higher yield of sugar than that shown by the original analysis of the beets. This is explained by M. on the ground that the beet contains a certain quantity of unfinished immature sugar, which, owing to the high temp., 100° or over, used in the diffusors, matures instantly, while in the old process where much lower temps. are used, this instantaneous maturing is not possible, but there is a destruction of sugar, due to the action of bacteria. A. G.

Juice-heaters. E. W. KERR. *Louisiana Bull.* 149; *Intern. Sugar J.* 17, 517-21 (1915).—A discussion of the factors affecting heat transmission with 2 tables of results of tests on juice-heaters relative to heat transmission, steam consumption and heat efficiency. A. GROSS.

The manufacture of sugar in Porto Rico. J. F. CLARENC. *Intern. Sugar J.* 17, 560-5 (1915).—An editorial summary of a report in *Bull.* No. 4, Part II, Dept. of Agr. Mauritius, containing production statistics, a description of the processes in 2 of the best factories and comparative control reports of 11 factories for 1914-15. A. GROSS.

The manufacture of sugar in Cuba. J. F. CLARENC. *Intern. Sugar J.* 17, 523-8 (1915).—An editorial summary of the report in *Bull.* 4, Part II, Dept. of Agr. Mauritius by C. on the sugar factories in Cuba. A. GROSS.

Sugar factory work in Natal. WM. CLACHER. *Intern. Sugar J.* 17, 504-8 (1915).—A description of the processes used for producing raw and refined sugar. A. GROSS.

Loss in tonnage of sugar beets by drying. H. B. SHAW. *Sugar* 17, No. 11, 55-8 (1915).—Beets were exposed under varying conditions to det. what losses might occur if storage was necessary. These expts. were conducted with a view to det. a system of payment for the beets. The av. daily shrinkage during 5 days in large uncovered piles was 2.92%, in covered piles the loss was reduced 0.9% per day. When the beets were thrown into small piles or were left scattered along the rows from which they were pulled, the shrinkage increased greatly, reaching 4.7% in 24 hrs. in a Utah expt. and an av. of 6.48% per day for 4 days in a Kans. expt. A. GROSS.

Charcoal prepared from molasses as a substitute for blood charcoal. H. FRIEDRICH. *Oesterr. Chem. Ztg.* 18, 137-8 (1915).—Blood charcoal is high in N and therefore valuable. Since it is required for fighting cholera and dysentery a cheaper substitute, such as molasses charcoal, is desirable. The latter is a bulky, tasteless and

odorless black powder and fulfills all of the requirements of a good blood-charcoal. Several comparative analyses are given. ARTHUR LEDERER.

Apparatus for the culture of yeast used for the determination of various sugars by fermentation (TRAMBICKS) 1. Oxidizing power of soils (GERRETSEN) 15.

Extracting sugar. W. A. RAMSAY. Brit., 18,515, Aug. 10, 1914. Bagasse, as it issues from the mill and while it is still under compression and shut off from the air, as by passage through a restricted chamber, is macerated in H_2O supplied under pressure.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

The Levi-Orthmann method of tannin estimation. R. LAUFFMANN. *Ledertechn. Rundschau* 7, 297-9(1915).—The method is described (cf. C. A. 7, 3249). L. finds that it sometimes gives higher results than the shake method with hide powder, and sometimes lower for the same kind of material. With sulfite-cellulose ext. the L.-O. method gives no ppt., but because of the absorption of I by the ext., the titration with $Na_2S_2O_3$ gives an apparent "tannin" content. L. B.

Note on the determination of tannin. D. B. DORR. *J. Soc. Chem. Ind.* 34, 1124-5 (1915).—The official (hide powder) method of the I. A. L. T. C. for detg. tannin has the objection that results produced by different analysts are not concordant. Tannin may be detd. by pptn. of the tannic acid by a metallic oxide. D. has had experience using a hot soln. of cupric acetate, which is added in excess to the warm infusion and the mixt. heated to boiling, the ppt. being collected on a filter and washed with hot water. After drying it is ignited, treated with HNO_3 , dried and again ignited. The wt. of CuO is multiplied by 1.305 to obtain the equiv. of tannin. Practically constant results are easily obtained, but they are 1% to 2% lower than the corresponding hide powder figures. Limited investigations seem to indicate that varying factors should be used for the different kinds of tannin, 1.45 for gallotannic acid (which would make the results more nearly correspond to those by the hide powder method), and 1.305 for the tannin in tea. The absorption by hide should be used as a check on the percentage indicated by the metallic oxide, while the latter is the more exact method on which to base analytical data. J. S. ROGERS.

Gravimetric method for the estimation of tannin. A. GAWALOWSKI. *Ledertechn. Rundschau* 7, 337-8(1915); see C. A. 9, 3378. L. B.

Color tests with skivers. OSCAR RIETHOF. *J. Am. Leather Chem. Assoc.* 11, 2-15(1916).—R. uses cow grain splits, the tanning soln. containing 80% as much tannin as the dry wt. of the skin. The residue of the soln. made up for analysis (0.4% tannin) is preferably employed. Tabulated results show the effect of variation in time, etc., on the proportion of tannin absorbed by the skivers. L. B.

Fermentations in tanning liquors. HUGO KÜHL. *Ledertechn. Rundschau* 7, 273-4(1915).—The well-known fermentations are described. Tanning material was extd. with water to which had been added a pure culture of an organism producing lactic acid, grown in a mixt. of 4 parts whey to 1 part water. The liquor so produced

was concd. and contained a higher amt. of tannin than an ext. made from a liquor obtained by leaching with water. L. recommends leaching with water which has been sterilized by heat, and introducing pure cultures of lactic organisms. L. B.

Depeptization during leather formation. W. MOELLER. *Collegium* 1915, 353-66. L. B.

Oak leaves and pine cones as tanning materials. C. SCHIFFKORN. *Collegium* 1915, 145-6. L. B.

A new method of chrome-tanning light skins. ANON. *Shoe Leather Rep.* 120, No. 10, 61(1915).—Butyric acid is used for deliming and bating when firm leather is wanted, and NH_4 butyrate for soft light leathers. Skins pickled in butyric acid may be chrome-tanned without the addition of HCl . Light skins are suitably delimited with NH_4 butyrate and then pickled with butyric acid. The process is described in detail. The leather is well tanned and has a soft grain and agreeable feel. Light skins may be drenched with NH_4 butyrate and pickled with formic acid and salt. Skins immersed in a weak bath of HCHO and drained will keep 2 weeks or more without pickling. Skins tanned with a weak soln. of HCHO resemble alum-tanned stock.

J. S. ROGERS.

Effluents of potassium salts factories and the leather industry. W. MOELLER. *Collegium* 1915, 373-82, 417-26.—Discussion of alleged ill effects on leather due to use of water from streams into which waste flows from factories producing K salts. L. B.

Sulfonated oils. G. BUMCKE. *J. Am. Leather Chem. Assoc.* 10, 559-69(1915).—B. objects to the assumption that total fatty matter is the difference between 100% and the sum of moisture, ash and unsaponifiable, because NH_3 and its salts will be lost from the ash, and if glycerol is present (as it usually is) it will be included in fatty matter; also sulfates of heavy metals in the ash are liable to partial reduction. For H_2O detn. B. recommends 100 cc. xylene instead of 50. Readings of water vol. after standing 12 hrs. should be made at about 21° . *Total fatty matter*: dissolve 4 g. oil in 20 cc. H_2O adding a little NH_3 and 30 cc. HCl dild. 1:5. Boil with glass beads under reflux condenser until oil and water become clear (about 15 min.). Cool and transfer to a separatory funnel with the aid of H_2O and Et_2O , shake and let settle. Draw off the water through a filter, wash the ether layer with H_2O until free from mineral acid, keeping the filtrate and wash water for detn. of SO_3 by pptn. with BaCl_2 . If petroleum ether is used instead of Et_2O the unoxidized fatty acids are sepd. from the oxidized; the latter being insol. in petroleum ether are left sticking to the flask, funnel and filter and may be dissolved off with hot alc. The solns. are transferred to tared dishes, the solvent evapd. and the fat weighed. SO_3 in salts is detd. by washing 10 g. of oil with Et_2O and NaCl soln., sepg. the aq. soln. and pptg. with BaCl_2 . SO_3 in sulfo-fatty acids is found by subtracting SO_3 in salts from total SO_3 . This wt. is multiplied by 4.725 for Turkey red oil or by 4.75 for other sulfonated oils to find the amt. of sulfo-fatty acids. The factor 4.75 is nearly correct for any oils whose liquid fatty acid is mainly oleic, but not for those which, like fish oils, contain considerable amts. of other liquid fatty acids. Unsaponifiable matter is detd. by the Spitz and Hönig method. The ash test is of little value, as oils neutralized with NH_3 show low ash, while those neutralized with fixed alkalis give high ash. Methods for Na_2O , NH_3 and NaCl are given. *Neutral oil*: 10 g. oil (20-30 g. Turkey red oil) are dissolved in 50 cc. H_2O in a 500 cc. separatory funnel, 20 cc. concd. NH_4OH soln. and 30 cc. glycerol are added, and when the oil is dissolved, 150 cc. Et_2O and 15 cc. alc. added and the funnel shaken vigorously. Sepn. will be complete on standing 2 to 3 hrs. A 2nd and 3rd extn. with 100 cc. Et_2O

each require 20 to 30 min. The combined exts. are washed with 20 cc. H_2O , then 20 cc. HCl dild. 1:10, and again twice with 10 to 20 cc. H_2O . The small amt. of fatty acid in the ether ext. is found by titration (mol. wt. 282) and deducted from the wt. found for the ether ext. The term "sulfonation value" has been employed to mean % of the total fatty matter which is not neutral oil. This is misleading, because the residue of fatty matter after subtracting neutral oil consists of (1) sulfo-fatty acids, which are the real products of sulfonation, (2) oxidized fatty acids, largely an indirect product of sulfonation, and (3) fatty acids which were partly present in the original oil, and were partly formed by the action of the acid.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 303, Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Journal Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Rack Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Part Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
columns } Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
} Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
} Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.....	10.00	12.00
} Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Journal Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets,
viz. 1. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 1.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,
Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

MARCH 10, 1916.

No. 5

I. APPARATUS.

J. C. JONES.

Platinum boats for carbon determination by direct combustion method. H. F. SIEVER. New Bedford, Mass. *Met. Chem. Eng.* 13, 525(1915).—While the initial cost of Pt boats is much greater than for other materials the life is so much greater in this method, that they are quite economical. S. has a Pt boat which has been used for some 25,000 combustions with a loss of weight of but 0.5 g. Care should be taken that the reaction does not take place at too high a temp., nor with too rapid a flow of O. The best results are obtained when the drillings just fuse together but do not lose their identity. Silica sand should be used freely in the boat. It is necessary to have a steel form on which to hammer the boat into shape occasionally. F. A. HARVEY.

A check valve for suction flasks. G. P. WALTON. *J. Ind. Eng. Chem.* 8, 57 (1916).—The valve is designed automatically to empty the flask as soon as the Gooch crucible is removed and so is useful only where the filtrate may be rejected. A short piece of $\frac{1}{4}$ in. glass tube is inserted in a hole in the flask near the bottom. A piece of heavy rubber tubing is then slipped over the tube and forced tightly into the hole. The end of the rubber should project about $\frac{1}{16}$ in. beyond the end of the glass tube. A piece of capillary tube with a $\frac{3}{8}$ in. bulb blown on 1 end and sealed at the other is then inserted stem first into the 2 tubes. Finally a piece of $\frac{1}{2}$ in. glass tube is forced over both tubes and bulb. An indentation in the side of the latter tube limits the motion of the bulb. As soon as the suction is put on the flask the bulb is drawn up against the rubber tube thus closing the valve. When the suction is broken by removing the gooch the pressure of the filtrate opens the valve and the filtrate is discharged.

F. A. HARVEY.

Gas generator. I. BERTIAUX. *Ann. chim. anal.* 20, 239-40 (1915).—This app. is provided with a manometer B, which also serves as a safety tube. The reacting material is placed in E, and the reagent to be added in A. The stopcocks are kept closed, except when the gas is being used. The spent liquor is withdrawn at g. Other forms of app. on the same principle are shown.

P. M. GIESY.

The use of cobalt nitrate for marking porcelain. S. B. KUZMIAK. *J. Ind. Eng. Chem.* 8, 89(1916).—It is claimed that the mark will be permanent and will stand a high temp. of ignition. The porcelain is gently heated with a low flame, then marked, using the sharp end of a burned taper or pen, then ignited with a strong flame for about 3 min.; a black mark is left. F. A. HARVEY.

Distilling apparatus. M. M. BROWN. Macon, Miss. *Dental Summary* 36, 50(1916).—A drawing and description of "an inexpensive and efficient distg. app." for the prepn. of small quantities of distd. H_2O . JOSEPH S. HERBURN.

Demonstration air thermometer, and a few physical and chemical thermal experiments. W. RORH. Greifswald. *Z. physik. chem. Unterricht* 28, 317-20(1915).—To the top of the cylindrical bulb is fused a narrow tube which is bent twice at right

angles, and on the long, vertical arm 2 safety bulbs are blown at some distance apart. A scale is attached between the bulbs, and the lower end of the tube dips into a colored soln. A 3-way cock is in the horizontal part of the tube for partly exhausting the app. and raising the soln. in front of the scale. Two knobs are fused near the top of the bulb and 1 at the bottom for winding wires in elec. expts. Several expts. are described.

J. H. MOORE.

Guarding against danger of burning and explosion in chemical processes with combustible fluids. H. HÜNEKE. *Chem. App.* 2, 281-4(1915).—Descriptions, with 6 cuts, of methods of reducing danger by surrounding and filling the app. with inert gas, and of the Martini-Hüneke app. for washing with benzine, which is claimed to reduce the benzine consumption to about 8% of the wt. of the goods cleaned.

J. H. MOORE.

Electrical pyrometry. ROBT. W. PAUL. *Trans. Eng. Ceram. Soc.* 14, 1-26 (1914-15).—A general article, describing especially the latest improvements in various types of pyrometers.

C. H. KERR.

Lubricating-oil testing machine. W. B. SLAUGHTER, JR. *Am. Machinist* 44, 71-2(1916).—S. describes a machine used at the Los Angeles testing laboratory. It consists of a motor-driven shaft, upon which rides an accurately machined bearing. Loads giving bearing pressures equiv. to those attained in practice are applied to the bearing to which measured quantities of lubricant are fed to the journal and distributed by a scoring in the surface of the gearing. The peculiar value of the machine lies in the method of applying the load, reading of the torque developed, and absence of calcs. in detg. the coeff. of friction. Temp. changes are read by a standard thermometer and provision made for the retention of the oil used. Parts are illustrated. Coeff. of friction is obtained directly from a chart, knowing the load applied and the deflection of torque-reading springs. $M = 4fPr/\pi$ plotted in rectangular coördinates. M = moment of friction in inch lbs., f = coeff. of friction, P = load on bearing in lbs., and r = radius of journal in inches. Abscissas are graduated in terms of micrometer readings and ordinates in terms of the coefficient of friction. A curve is shown.

W. H. BOYNTON.

Apparatus for evaporating aqueous extracts (ALDRICH) 11B.

Electric resistance thermometers. CAMBRIDGE SCIENTIFIC INSTRUMENT CO. and W. H. APTHORPE. *Brit.*, 20,248, Sept. 26, 1914. An elec. resistance thermometer is made by winding a doubled metal wire in a double screw-thread cut on the outside of a rod or tube of porcelain, steatite, glass, etc., then coating the surface of the rod or tube with a fusible material, and finally heating the whole to fuse the material on to the surface.

Thermoelectric battery. H. HAUSRATH. *Brit.*, 20,009, Sept. 21, 1914. A thermopile for measuring radiation or elec. energy is composed of stacks of thin plates, between which are clamped the outer ends of the elements.

Evaporators. FAWCETT, PRESTON & CO. and A. M. LANG. *Brit.*, 19,568, Sept. 9, 1914. App. for evapg. liquids comprizes a number of sep. superposed vessels each containing a set of inclined heating tubes and communicating with a common sepg. chamber receiving the vapor and liquid issuing from the tubes. The unevapd. liquid is returned by a pipe partly to the same vessel and partly to the vessel next below. The vapor is compressed by a steam jet compressor into the heating space around the tubes in the superposed vessels, the steam passing from vessel to vessel through pipes. Excess steam escapes to a feed-heater. The sepg. chamber is preferably

arranged to one side of the superposed vessels. The vapors escaping from the upper ends of the tubes flow past a baffle into a chamber while the liquid is received on a tray fitted with a weir over which a portion flows to pass by a pipe to the vessel next below. The pipe withdrawing liquid for recirculation in the same vessel is connected with the tray on the other side of the weir.

Evaporating and concentrating liquids. FAWCETT, PRESTON & Co. and A. M. LANG. Brit., 19,567, Sept. 9, 1914. In an evaporator having a heating chamber containing tubes extending between upper and lower downwardly inclined tube-plates, the tubes are inclined so as to enter the tube-plates at right-angles, and the lower tube-plate is formed in two or more stepped parts. By forming the lower tube-plate of the heating chamber in steps the lower ends of the inner set of tubes come close to the bottom of the evaporator, thus improving the circulation at that part. Steam may be introduced into a jacket formed by an annular concave plate secured to the bottom of the evaporator.

Filtering liquids. T. K. IRWIN. Brit., 19,901, Sept. 17, 1914. Each stage of a multi-stage app. for the filtration and aeration of sewage or other liquid comprises a fine bed of sand, etc., adapted to serve as a filter, a coarse bed of clinker, coke, etc., adapted to serve as a surface-contact bed, and a lower chamber into which air or gas is introduced at each stage from a supply pipe. The liquid to be filtered enters through a conduit while the filtrate passes through another conduit, the sludge, etc., passing through a perforated partition and being drawn off.

Cooling towers. W. W. WHITE. Brit., 19,646, Sept. 10, 1914. The liquid drops from troughs on to saucer-shaped plates and thence flows in thin streams along shallow gutters, which may be formed by the surfaces of laths or planks, arranged in a zigzag manner in parallel vertical sets, the direction of inclination being reversed from set to set so that transverse air passages are formed, free of falling H_2O . The lower ends of the planks are supported in members and are notched so as to direct the H_2O on to the plank below.

Cooling apparatus for steam jets on hollow grates. S. POMERANZ. Ger., 285,435, Mar. 11, 1913.

Revoluble tube furnace. FELLNER & ZIEGLER. Ger., 285,419, Nov. 29, 1913. The construction has in view the prevention of deposits.

Continuously operating heating vessel. STREBELWERK, G. M. B. H. Ger., 285,201, Feb. 5, 1914. Provision is made for the reflux of tar from the smoke channels.

Apparatus for cleaning boilers. H. BASCHI. Ger., 285,287, Sept. 17, 1914.

Surface-apparatus for heating and cooling fluids. A. J. E. MUTERS. Brit., 20,017, Sept. 21, 1914. The app. comprises a number of hollow elements mounted on a central shaft and so arranged one above the other as to leave spaces between the elements, the elements being in communication with one another through passages in the shaft and the spaces between the elements being in communication with one another through other passages. The spaces between the elements are placed in communication with one another at their outer ends by parts projecting from the elements.

Vessels for use in analysis. H. ZELLNER. Brit., 19,914, Sept. 18, 1914. Vessels for use in measuring in analytical operations are formed as an open miniature balance pan, tube, flask, or boat made of foil of Sn or Cu or an alloy or amalgam of these metals. The substance to be tested is measured out in the vessel, and then both vessel and substance are introduced into a flask, etc.; when the vessels are formed of amalgams, they serve to supply the contact substances necessary in certain operations. In preparing the amalgams, Cu and Hg are first amalgamated in the usual manner, and then

this amalgam is poured in the molten condition on to molten Sn. To prevent the alloy from becoming brittle, a small quantity of Pb may be added.

Acetylene generator. F. H. MCGURK. U. S., 1,163,887. Dec. 28.

2. GENERAL AND PHYSICAL CHEMISTRY.

Some scientific advances during 1915. H. R. HOSMER. *Gen. Elec. Rev.* 19, 92-3(1916).—H. briefly reviews the work of T. W. Richards, Langmuir, Kalmus, Rittman, *et al.* C. G. F.

History of the development of hydrometry. EDMUND O. VON LIEPMANN. *Chem. Ztg.* 39, 983-6(1915); cf. Schelenz, *C. A.* 10, 299.—A brief bibliography is given.

J. H. MOORE.

Work of the Physikalisch-Technische Reichsanstalt in 1914. *Z. Elektrochem.* 21, 501-11(1915); cf. *C. A.* 9, 3148-51. Radiation measurements: improvements in the methods. WARNBURG AND MÜLLER.—The investigations of vacuum radiation were continued, and the following improvements proposed: (1) To det. constancy of temp. of the vacuum radiator and of other cases in which the thermoelectric method is not applicable, a special form of bolometer (Haltebolometer or Mittelblockbolometer) is used. The instrument is set in a larger water bath so that the furnace radiation must penetrate a greater H₂O layer, the bath being kept at const. temp. by an elec. thermostat. (2) The formula previously reported (*C. A.* 7, 3700) for calcg. spectral intensity measurements with the mirror spectrometer was based on expts. with freshly silvered mirrors; this is not exactly correct as the reflectivity diminishes with the age of the mirrors. In a new series of expts. on the reflectivity of the mirrors, the wave lengths were measured by the method of Hagen and Rubens. Determinations of the constant c . WARNBURG AND MÜLLER. Applying the above improvements to the methods previously used (*C. A.* 7, 3700), new detns. of c were made with: (1) the vacuum-carbon radiator between the m. p. of Au and 1400°, and the m. p. of Au and 1700°; (2) the Lummer-Kurlbaum open radiator between m. p. of Au and 1400°; (3) the L.-K. model with linear dimensions of double size, but with relatively smaller opening of the inner screen, between same temp. limits. The new expts. show a better agreement among themselves than the old and give a smaller value to c , to be published later. All expts. were made with the new quartz prisms. Recent expts. of Paschen show deviations from the Carvallo dispersion formula in the 5th decimal place of the refraction exponent sufficient to make changes of almost 1% in the value of c . Temperature determinations according to the Wien displacement law and the Stefan-Boltzmann law. WARNBURG AND MÜLLER. Using the large L.-K. model, detns. were made at the same temp. according to the Wien law and according to the Stefan-Boltzmann law; the diam. of the furnace opening was increased from 5 to 10 mm. and the bolometer was placed in the center of a reflecting Ni hemisphere. Under these conditions the temp. detns. by both methods based on the Carvallo dispersion curve were almost in complete agreement. Light unit. WARNBURG AND MÜLLER. A rational light unit can be obtained only through vacuum radiation, holding the radiator at a temp. of about 3000°. Expts. have been initiated with the vacuum-C radiator, holding the temp. const. with the improved bolometer. For reproducing the temp. the method of Lummer and Kurlbaum was used in which a definite reduction of the total radiation is effected by absorption. For this a 2 cm. thick layer of a 10% K₂Cr₂O₇ soln. between quartz plates was used. The light radiation could be reproduced up to 0.4%. Further work is in progress. Energy law of photochemical process. WAR-

BURG. See *C. A.* 9, 883, 2348, 3149. Absorption of ultraviolet radiation. WARBURG. See *C. A.* 8, 613; 9, 2480, 2836. Measurement of ϵ/μ . GEHRCKE AND JANICKI. Further work is reported on the cathode dusting method. Metal plates of Pt, Au, Cu, and Zn were subjected to the rays of a Hg quartz lamp *in vacuo* and studied to det. the reproducibility of the potential charges of the plates. The charges were reproduced only when the plates were thoroughly "cleansed" by previous cathode dusting. The potential charge depends mainly upon the gas in which the dusting has been effected and only slightly upon the metal. After dusting in H the highest potential was found, viz., 2.44 v. for Pt, Au, Cu; 2.62 v. for Zn. Dusting in H_2O vapor gave lower and less const. values of 1.8 to 2.3 v.; in He the lowest value (1.8 v.) was obtained. These potentials were reproducible and stable for hrs., as long as the vacuum was held const. by liquid air. It was immaterial whether liquid air or liquid H, with or without coconut charcoal, was used in producing the vacuum. No reproducible potentials could be obtained with Al. Light emission of metal vapors. in the glow discharge. JANICKI AND SRELLIGER. In the emission spectra of Cd, Zn, Mg, Pb, Al, Sn, Ag and Si there is a parallelism on the one hand between sparks and negative glow, on the other between arcs and positive columns; Te shows no such analogy. Expts. with Zn and Cd in externally heated Geissler tubes with inner electrodes confirmed the results with these 2 metals. Testing of radioactive preparations. GEIGER, BOTHE AND JANICKI. The total content of 395 strongly radioactive preps. examd. corresponded to about 8230 mg. Ra element (including 49 meso-Th preps. with a Ra equiv. of 1181 mg.); 102 preps. at time of examn. were not yet in radioactive equil.; 13 feebly radioactive preps. tested contained amts. of Ra of the order of magnitude of 10^{-8} to 10^{-4} mg. Ra element per g. of substance. Apparatus for testing feebly radioactive preparations. BOTHE. See *C. A.* 9, 3026. Theory of the normal elements. VON STEINWEHR. Kohnstamm and Cohen (*Wied. Ann.* 65, 344(1899)) and Holsboer (*Z. physik. Chem.* 39, 691(1902)) have reported a transformation point at 15° for $3CdSO_4 \cdot 8H_2O$; the work and conclusions of these authors are critically discussed, calcns. from their data giving a much lower temp. than 15° . New measurements were made of the differential heats of diln. of $CdSO_4$ solns. and the temp. coefficients of this heat tone calcd. From these data and older values the theoretical heat of soln. and its temp. coeff. were computed; from these 2 magnitudes the temp. of the change of sign of the theoretical heat of soln. and the minimum soly. agree to $+3^\circ$ with the soly. expts. of Mylius and Funk (*Ber.* 30, 825(1897)). In the calcn. of the chem. energy the new values for the e. m. f. of the elements were used (electrochem. equiv. of 96494 (instead of 96540), elec. equiv. of heat = 0.2389). The results (47252 cal. calorimetrically and 47427 cal. electrically) show better agreement than earlier values. Calorimetric detns. of the temp. coeff. of the chem. energy of the elements gave +19.45 cal./degree; electrical detns. using the temp. formula of Jaeger and Wachsmuth for the Weston element gave +17.44 cal./deg. The Wolff formula gave +21.10 cal./deg. This shows that Cohen's criticism (*C. A.* 5, 1014) of the Jaeger temp. formula is not tenable. Cf. *C. A.* 8, 3146; 9, 3149. Mercurous sulfate. v. STEINWEHR. Hg_2SO_4 is prepd. in large amts. for normal elements by E. de Haën, Hannover, under the supervision of the Reichsanstalt. The salt is kept under a satd. soln. of $CdSO_4$ (cf. Warburg, *C. A.* 9, 1007). Silver voltameter. JAEGER AND V. STEINWEHR. A note describing briefly the different forms of Ag voltameter and calling attention to the work set forth in other publications (cf. Rosa, *et al.*, *C. A.* 8, 3154). Mercury resistance thermometer: change of resistance of Hg between 0 and 100° . JAEGER AND V. STEINWEHR. See *C. A.* 8, 2297; 9, 749. Theory of mercury rectifiers. JAEGER. The oscillographic curve for electrolytic and Hg rectifiers has been investigated with a view to detg. the "minimum potential" which must be overcome. Cur-

rent and voltage curves of Hg rectifiers in different combinations with ohm resistance, capacities and inductances are calcd. and explained with figures. Cf. Schulze, *C. A.* 9, 24, 414, 1007. Weak-current laboratory. See normal elements, *C. A.* 9, 3150. Electrical measuring technics laboratory. FUSZNER. A description of a new lab. and its equipment. Comparison of platinum and helium thermometers below -193° . HENNING. The work previously reported (cf. *C. A.* 7, 2892) has been continued. Different resistance thermometers were compared with a He gas thermometer in baths of liquid air and liquid H, which boiled under normal or reduced pressure. For the intervals 80° and 62.5° , and 20.3° and 16.4° abs. temp. the resistance ratio (Pt thermometer No. 30) $R = r/r_0$ as a function of the abs. temp. T may be calcd. by the empirical equation $\log (R - 0.0038) = -1.71496 + 0.76176 \log T - (34.985/T)$ with an accuracy of about 0.02° . This formula has not been tested for the interval between $T = 62.5$ and 20.3° . With Pt wires of same m. p. as No. 30, the equation holds with approx. the same consts. (cf. Henning, *C. A.* 9, 3148). The quadratic reduction formula for R of different thermometers held above -193° (at b. p. of O and at b. p. of CO_2) regardless of the variety of Pt; at lower temps. it does not suffice for all the varieties of Pt, e. g., 2 varieties of Heraeus very pure Pt at the b. p. of H gave R at $T = 20.3^{\circ}$, 0.0060 and 0.0082. Boiling point of hydrogen. HENNING. The normal b. p. of H was detd. by immersing a He thermometer directly in the boiling liquid. The results were the same whether the liquid was stirred or not. Measurements agreeing within the limits of observation (0.02°) with 2 different fillings of the gas thermometer (initial pressure $p_0 = 740$ mm.) gave the normal b. p. $t = -252.79^{\circ}$; reduction to 760 mm. being calcd. by the coeff. of Onnes, $dt/dp = 0.005^{\circ}$ per mm. Applying the correction calcd. by Berthelot's method ($+0.004^{\circ}$) for the thermodynamic scale the normal b. p. on this scale $t = -252.79^{\circ}$. This result is not final as the thermal coeff. of expansion of the gas thermometer vessel (Jena glass 59^{III}) was based on a value which by extrapolation gave an equation holding only to -193° . Onnes and Keesom in 1913 reported the normal b. p. of H on the thermodynamic scale = -252.76° . Comparison of different gas thermometers. HENNING. Const. of Pt resistance thermometers. The results together with previous measurements at 445° in which A thermometers were investigated, are reported in a table, the He, N, or A thermometers giving higher readings than the H. The results were calcd. by the formula $t_0 - t = p_0 (T_c^3 - p_c) + 517 \times 10^{-9} [t(t - 100) (t + 273)]$, which according to the Berthelot equation of state, gives the temp. difference $t_0 - t$ of the thermodynamic scale (t_0) against the scale of a gas thermometer of const. vol. (t) at the initial pressure p_0 . T_c and p_c are the abs. critical temp. and press. of the gases. The results show that the B. equation does not present with sufficient accuracy the deviations of the different gas thermometers within the observed temp. range. Measurements with platinum thermometers in Leiden and Teddington. H. SCHULTZ. Three Pt thermometers of the Reichsanstalt were taken to Onnes' laboratory at Leiden and to the Natl. Physical Lab. at Teddington. In Leiden the resistance thermometer No. 35 (Pt exceptionally pure; 20.3° and 14.7° abs. The temp. was detd. from the vapor pressure of H, which, according to the measurements of Onnes and Keesom, is a function of the temp. measured on the thermodynamic scale. Measurements with the same instrument at the Reichsanstalt gave $R = 0.00000$ at $T = 20.38^{\circ}$ (He scale); by interpolation of the Leiden observations this value of R corresponds to 20.33° (0.05° higher). Aside from expd. differences this difference is explained by the difference of the temp. scale of the Leiden lab. and in the Reichsanstalt, O. and K. using a value for normal b. p. of H 0.03° higher. Barker in the Natl. Physical Lab. has tested Pt thermometers Nos. 10 and 13 at the b. p. of

S. The measurements were made with 2 b. p. app., one of Fe, the other of glass. The Reichsanstalt measurements were made in a glass boiling-tube, the av. results of a series of concordant measurements being reported. The results of the 2 institutions show good agreement. **Specific heats of gases at low temperatures.** H₂USZ. The sp. heat of A at a pressure of 1 atm.: at $+20^{\circ} = 0.1263$ g. Cal. $_{15}$ /g. degree, at $-180^{\circ} = 0.1317$ g. Cal. $_{15}$ /g. degree. From Berthelot's equation for the ratio of the sp. heats in ideal gases, α at $20^{\circ} = 1.651$. The deviation of this value from that (1.667) for monoatomic gases by the kinetic gas theory is of the same significance as was observed with He (cf. C. A. 9, 3148). **Equation of state of gases.** HOLBORN AND H. SCHULTZE. Cf. C. A. 10, 416. The $p\bar{v}$ value for pure He was detd. at 0° , 50° , and 100° for pressures of 19 and 38 m. of Hg. Within these limits the isothermals are rectilinear; the values of Onnes at 0° and 100° within this pressure range show deviations up to 0.1% from the rectilinear. Expts. were interrupted by the war. In order to check the pressure measurements within an accuracy of 0.03%, the pressure balance, which had been compared with a Hg manometer at 16 atm., was tested for higher pressures. For this purpose 2 similar balances, standardized as above, were compared with one another at pressures up to 200 atm., showing a variation with the pressure and necessitating a direct comparison with the Hg manometer which is outlined. **Specific heats of gases at high pressure.** HOLBORN AND JAKOB. Expts. on the av. sp. heat of air between 20° and 100° were extended to 300 atms., but the outbreak of the war has interrupted the work. **Liquefaction of hydrogen and helium.** MEISSNER. Improvements in the plant for the liquefaction of gases have reduced the amt. of liquid air used for precooling in the liquefaction of H from 2.5 to 1.75 l. per hr. During the yr. 33 l. of liquid H were produced. According to Onnes the production of a few hundred cc. of liquid He requires 25 l. of liquid H, the production of which requires about 75 l. of liquid air. An investigation is in progress looking to a simpler and more economical process. Expts. without definite results have been made on the liquefaction of H without precooling with liquid air, based on the use of the external performance of the compressed H. In the liquefaction of He the precooling with liquid H cools the He to a little below the inversion point for the Joule-Thomson effect, so that the latter is very small; an improvement appears possible by the use of the external performance of the compressed He, e. g., on a turbine as suggested by Rayleigh. **The testing of laboratory and other thermometers** (normal, meteorological, calorimeter, etc.) is reported, number of tests made and accuracy required being given. Seven per cent. of thermometers tested were rejected. **Comparison of mercury with platinum thermometers between 0° and 100° .** HOLBORN AND SCHEEL. A series of Hg thermometers were compared among themselves and with 3 Pt resistance thermometers in the interval 0° to 100° . Two thermometers of the *verre dur* of the Internatl. Bureau, 2 inclosed scale thermometers of Jena glass 16^{III} and rod thermometers of Jena glasses 16^{III} and 59^{III} were tested. Results are reported in a table, the values agreeing for each temp. (20° , 40° , 50° , 75°) within the limits of error of about 0.005 $^{\circ}$ for the 3 scales (internatl. H scale, testing lab. scale and the scale used in the radiation measurements above). **Comparison of mercury and platinum thermometers between 100° and 300° .** HOFFMANN AND MEISSNER. See C. A. 9, 2331. **New thermometer glasses.** SCHEEL, GRÜTZMACHER AND MOELLER. The work is progressing, though not completed, owing to the personal supervision required in the factory and the time and care necessary in the calibration. Twelve normals of different glasses have been calibrated and compared; the softening temp. and expansion of some glasses were detd. dilatometrically; one glass is being tested for the manuf. of clinical thermometers. **Electrical and optical temperature measurements.** HOFFMANN AND A. SCHULZE. Tests reported on thermoelements, using 3 elements of Pt-(Pt-Rh) from 100° to 1100° as instruments of precision. Two elements of constantan-Cu and 1 element of constantan-Fe below 0° were tested; 8

elements of constantan-Fe and 1 of constantan-W up to 800-900° were tested, two of Ni-(Ni-Cr) up to 1100°. A study of the behavior of thermoelements of the base metals on continued heating at high temps. in the elec. furnace showed that in elements consisting of strong tubes or rods the thermal force did not change more than 5° to 10°; such constancy can be attained only when the element, before being used for temp. measurements, is heated throughout its length in order to reduce any irregularities (lack of homogeneity). Elements of constantan-Fe, constantan-steel tube, and Ni-35% Ni steel withstood a temp. of 800° for 250 to 300 hrs.; an element of Ni-66% Ni steel withstood 1000°. Elements of Ni-C for an av. of 275 hrs. at a temp. of 1200° did not change more than 10°; Ni-(Ni-Cr) (10% Cr) at 1000° for longer periods changed not over 10°. The thermo-electric behavior of W, Mo, and Ta is being studied. **Special tests.** MOELLER AND HOFFMANN. The heats of combustion of lamp filaments of W and W powder were detd. The m. p. (273°) of Bi prepd. in the lab. was detd. by sealing the metal in a glass tube; the m. p. and solidifying point were detd. with a thermoelement. **Chemical work.** Preparation of pure metals. MYLIUS. The work of the Reichsanstalt has enabled German factories to produce the following metals of great purity: Hg, Ag, Au, Pt, Cu, Sn, Zn, Cd, Pb, Bi, Sb, Fe, Ni, Co, Ir, Rh, Ru, Os. The impurity of the factory products never exceeds 1:10⁴. The prepn. of pure Pt from Na₂PtCl₄ was accomplished by Mylius and Foerster (*Ber.* 25, 665(1892)); methods of Pt analysis (cf. *C. A.* 9, 419). The Pt of commerce always contains numerous impurities in small amts., e. g., Heraeus purest Pt contains traces of Ir, Pd, Au, Cu and Fe (=1:10⁴ impurity). Readily detectable amts. of Pt, Ag, Sn and Zn are normally present in the pure electrolytic Bi, while Kahlbaum's purest Bi (in 1914) prepd. by chemical methods contained as impurities: Ag trace, Cu 0.001%, Pb and Fe traces (=1:10⁴⁻⁵). A table is given showing amts. of impurities in Bi from various sources. The sp. elec. resistance of Bi wire from Hartmann and Braun was found by Steinhaus and Werner to be 1.290 at 22°; of Bi prepd. by Lenard's process (*Ann. Physik. Chem.* 39, 642(1890)) varies from 1.088 to 1.157. Groschuff's work on a commercial Sb shows the need for improved chemical methods. For the sepn. of Sb from its solns. it is suggested that one use the H₂O-decomposable, crystd. compd. of SbCl₃ with HCl, which is pptd. by passing in HCl-gas. The impurities are concd. in the mother-liquor and then detd. Kahlbaum's "technical" Sb contains as impurities Cu, Pb, Fe, Ni, Co, Sn, and As (impurity = 1:10³); K.'s "pure" Sb is of higher purity, but the ratio of the impurities to Sb has not been established. **Nickel and cobalt.** MYLIUS AND HÖTTNER. Expts. on the purification of impure Ni and Co by the crystn. of the simple salts (nitrates, chlorides, sulfates, etc.) resulted more in the removal of impurities (Cu, Fe, Mn, Zn, etc.) than in the sepn. of Ni and Co, as the salts of the latter are very similar in soly. and readily form mixed crystals. For the complete sepn. and purification, complex compds. characteristic of 1 metal only must be used: for Ni the rose colored double nitrite Ni(NO₂)₂(NH₃)₄; for Co the purpureo salt Co(NH₃)₆(NO₂)₂. The use of these and other salts is being studied. **Platinum substitutes.** GROSCHUFF AND LENZ. Wires of Pt-Ag alloys have been tested for use in incandescent lamps. Time expts. with such wires containing 25% Pt have been conducted with reference to the required "vacuum density."

F. W. SMITHER.

The temperature scale of the Physikalisch-Technischen Reichsanstalt and the unification of temperature measurements. L. HOLBORN. *Z. Elektrochem.* 21, 559-62 (1915).—A review of the thermometry work of the Reichsanstalt. Cf. *C. A.* 9, 3148-51 and preceding abstract.

F. W. SMITHER.

Law of fall of drops of oil in air and the charge of the electron. A. SCHIDLOW AND J. MURZYNOWSKA. *Arch. sci. phys. nat.* 11, 386-99(1915).—The expts. were undertaken to remove the discrepancies between various workers on the value of the ele-

mentary charge. The principle of the method is similar to that of Millikan; a drop of oil is produced, charged by mechanical pulverization, and allowed to come between the plates of a horizontal condenser. In this paper the corrections have been calcd. and the exptl. details given. Data will be given in a future paper. E. B. M.

✓ The theory of the solubility of gases in liquids. G. JÄGER. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 287-304(1915).—Both from hydrostatic equations and from the kinetic theory of matter the following formula for α , the soly. of a gas in a liquid, is readily deduced: $\alpha = e^{-A/RT}$, where A is the work done by the surface forces in transforming 1 g. mol. of the gas from soln. into vapor, T is the abs. temp., and R is the gas const. An empirical formula for A has the form $A = A_0 [1 + at (1 - bt)^2]$, where A_0 , a , and b are const. Comparison with the data for aq. solns. of various gases shows that b is a const. for nearly all gases and on the av. identical with the temp. coeff. of the capillarity const. of water. The gases when arranged in order of decreasing A_0 are in the order of increasing a . G. L. WENDT.

The variation of surface tension with temperature. ALLAN FERGUSON. Univ. North Wales, Bangor. *Phil. Mag.* 31, 37-47(1916).—The validity of the equation $T = T_0 (1 - b\theta)^n$, in which T is the surface tension of any liquid against its vapor at the temperature θ , and b and n are const., has been extended to 14 org. liquids. It gives very accurate values for the critical temperature, θ_c , when $T = c$, through the equation $\theta_c = 1/b$. Values of surface tension may be calcd. from it with greater accuracy than from van der Waals' formula. From the data of Morgan and Schwartz (*C. A.* 5, 2586) the formula is shown to hold also for surface tension against air, but it is never valid for "associated" liquids. The value of n varies among liquids but is always close to 1.21. Among organic esters b diminishes, and θ_c increases, with increase of the hydrocarbon residue and is greater for an iso-compound than for the normal one. A possible relation of b with the abs. boiling point is suggested. G. L. WENDT.

The structure of silver crystals. L. VEGARD. Univ. Christiania. *Phil. Mag.* 31, 83-7(1916).—By the use of a Bragg X-ray spectrometer, cubic crystals of Ag were found to have a simple face-centered lattice structure. G. L. WENDT.

Ionization of phosphorus. JOHN LANDIN. *Svensk Kem. Tidskrift* 27, 157-9 (1915).—The literature pertaining to the ionization of yellow P is referred to and the assertion is made that amorphous P also ionizes under the same conditions. Ionization of both forms of P is very weak at room temp. but on ignition becomes very strong. Burning P in an atm. of Cl_2 causes more ionization than burning in O_2 . The highest reading of volts was in the 1st min. after the first discharge; 2 min. thereafter this had dropped in one expt. from 2.388 to 1.725 and a 2nd discharge dropped to 1.038 and finally to the control values. The measurable ionization disappeared before the P vapors had condensed in the electroscope. A. R. ROSE.

Determination of Avogadro's constant by the study of the Brownian movement of the particles of gold hydrosols. ARNE WESTGREN. Upsala. *Z. anorg. allgem. Chem.* 93, 231-66(1915); cf. *C. A.* 9, 737.—Expts. were made with Au hydrosols to det. whether or not Stokes' law is applicable to such solns., and to det. the Avogadro constant by Perrin's method. The value of N was calcd. by Einstein's formula for each of a series of hydrosols, the sedimentation equil. being detd. by a method similar to that used by Perrin. The size of the particles was detd. directly, and by application of Stokes' law; the 2 methods showed excellent agreement. In the series of hydrosols studied the vol. of the particles was varied 8-fold, and the kinetic energy of the particles remained independent of their mass. Stokes' law was found to hold valid, and the mean value found for N was $60.5 \pm 3 \times 10^{23}$. GEORGE W. MOREY.

The capacity of salts of sodium and potassium to form compounds and crystal mixtures. I. M. AMADORI. Univ. Padua. *Atti ist. Veneto sci. let. arti* 72, II, 903-31; cf. *C. A.* 8, 847.—A. has shown that corresponding Na and K salts yield mixed crystals on crystg. from their fusion mixt., indicating their complete isomorphism at high temps. The temp. of formation of the compd. approaches that of crystn. only in the case of the molybdates and tungstates. With lowering of the temp., so that other cryst. forms intervene, the mixed crystals break up, yielding a mechanical mixt. or a mixt. of the salts for the most part in the ratio of 1:1. At ordinary temp., there is practically no soln. between the salts of Na and K. The chlorides and nitrates are not miscible at this temp.; the sulfates and chromates form a compd.; other salts form cryst. hydrates (particularly the Na salts) on crystg. from aq. soln. It is noteworthy that in some cases, where the miscibility is complete at high temp., it decreases with diminution of temp., finally becoming practically *nil*. This occurs in cases even where the 2 sets of crystals have the same cryst. form, as in the case of the chlorides. This shows that the single crystal form is not sufficient to indicate isomorphism between 2 salts, since for the same forms there may be variations in the degree of miscibility. II. *Ibid* 73, II, 1679-89. Further expts. with the arsenates of Na and K show that partial solubility occurs between the meta-arsenates. Complete miscibility at solidification is shown in the case of the ortho- and pyroarsenates. In both cases, this ceases on lowering the temp. The ortho-arsenates of these metals exhibit a behavior analogous to that of the corresponding carbonates. In the case of the pyroarsenates, expts. show that there is evidently formed a mixt. of the β -forms of the 2 salts in equimol. proportions, as well as the stable compd. that is formed from the crystal mixt. of the α -forms. An analogous interpretation is likely applicable to the phenomena observed in the case of the pyrophosphates, the Na and K salts of which behave similarly to the sulfates and chromates.

L. T. FAIRHALL.

Conductivities of certain organic acids in absolute ethyl alcohol. H. H. LLOYD, JOHN B. WISEL AND HARRY C. JONES. *J. Am. Chem. Soc.* 38, 121-31(1916); also in *Publ. Carnegie Inst. Washington* No. 230(1915); cf. *C. A.* 8, 3735.—All the measurements were made in alc. containing not more than 0.04% H₂O and with a sp. cond. averaging 2×10^{-7} . The mol. conds. at 15°, 25° and 35° in approx. *N*/8, *N*/32, *N*/128 and *N*/512 solns. were detd. for the following acids: (the cond. at 25° in *N*/32 soln. is given) phenylacetic 0.01614, hydroxyisobutyric 0.01813, bromopalmitic 0.02316, malonic 0.0555, ethyl- 0.8345, diethyl- 0.08044, propyl- 0.1049, dipropyl- 0.09058, butyl- 0.0363, allyl- 0.03882, benzylmalonic 0.06189, bromo- 0.1177, dibromosuccinic 0.04816, sebacic 0.005566, dithioglycollic 0.04269, benzilic 0.07267, maleic 0.3768, fumaric 0.01291, itaconic 0.07795, mesaconic 0.01636, phenylpropilic 0.04278, aconitic 0.03403, benzoic 0.01405, *m*-chloro- 0.01610, *m*-nitro- 0.02308, 3,5-dinitrobenzoic 0.04113, picric 6.264, sulfosalicylic 30.68, *o*- 0.03400 and *p*-aminobenzoic 0.2910, *o*- 0.01637 and *p*-toluic 0.004444, cinnamic 0.004603, phthalic 0.1077, dichlorophthalic 0.06579, anisic 0.01662 (*N*/8), mandelic 0.01680, and camphoric 0.01539. In nearly all cases the conds. are several hundred times smaller than in H₂O; increase in diln. increases the cond., the increase in many cases being almost proportional to the vol. Assuming, from Goldschmidt's work (*C. A.* 9, 745), that the limiting conds. are not far from 90, the dissociation of the above acids in no case exceeds 2%, even in *N*/512 soln. The relations between structure and cond., as brought out in this work, are briefly discussed.

C. A. ROULLER.

The shape of molecules. II. TH. SVEDBERG. *Arkiv. Kem. Min. Geol.* 5, No. 11, 1-6(1914); *J. Chem. Soc.* 108, II, 628.—In former articles S. has dealt qual. (*C. A.* 7, 2504) and quant. (*C. A.* 8, 1372, 2097) with a method which may be used for

ascertaining the dis-symmetry of the molecules, and in the present paper the results of certain series of measurements are given. Using the anisotropic substance azoxy-phenetole as solvent, and measuring the elec. cond. of a dissolved electrolyte or the velocity of diffusion of a dissolved nonelectrolyte in directions parallel and at right angles to the direction of the axes of the solvent molecules, it is possible to calc. the ratio between the 2 axes of the solute molecules, assuming that these molecules consist of rotation ellipsoids; the measurements are carried out at various temps. below that of the clearing point of the solvent. Using phenol, *o*-nitrophenol, quinol, and pyrogallol as solutes, the axial ratio of the benzene mols. was found to be 1.63. With β -naphthol and sodium α -dinitronaphthol as solutes, the axial ratio for the $C_{10}H_8$ mol. was calcd. to be 2.93. If it is assumed, among other things, that the C_6H_6 and $C_{10}H_8$ mols. are ellipsoidal in form, and further that their minor axes, b and c , are of the same length in the 2 mols., it can be calcd. that the relative lengths of their major axes are 1:1.79, that is, numbers are obtained which are in qual. agreement with the ratio 1.63:2.93 of the numbers given above.

E. J. C.

A criticism on van der Waals' equation and some new equations derived therefrom. JAMES KAT. *Phil. Mag.* 31, 22-36(1916).—The factor b in van der Waals' equation is amended by the use of the term b for the vol. of N mols. filling a vol. $V + b$ at a pressure of RT/V , while β is the vol. of N_1 mols. filling the vol. V at the same temp. and pressure. Then b is a const. and β a variable which decreases as V decreases. For large values of V , N_1 is almost equal to N and β to b . In any actual gas only N_1 mols. give a pressure which would be given by N mols. of a perfect gas, and N_1/N is defined as the sp. d. This decreases with increasing compression and in the critical state is for all substances $2/3$ of the theoretical density, whence $\beta = 2b/3$, and the critical vol., $V_c = 3\beta$. The usual soln. of the equation in powers of V_c is not justified since it assumes that the pressure is the inverse value of the vol. and does not allow for the actual value of b . If $V_c = 2b$, or 3β , is used the pressure on the gas from the exterior at the critical state, $P_c = RT_c/2V_c$, or $2P_cV_c = RT_c$. The total critical pressure $\pi_c = P_c + P_{1c}$, where the latter term is the "inward pressure" due to van der Waals' factor a . P_c is shown to equal P_{1c} , whence $\pi_cV_c = RT_c$, i. e., the "gas law" holds good for the critical state. Values of P_c calcd. from the equation $2P_cV_c = RT_c$ show fair agreement with the facts for 27 gases given. If $P_c = P_{1c}$ at the critical state, surface tension and latent heat of vaporization disappear at that point.

G. L. WENDT.

The kinetic theory of gases. I. SAUL DUSHMAN. *Gen. Elec. Rev.* 18, 952-6 (1915).—The first of a series of articles in which D. elucidates the theory of gases in an elementary manner and discusses the principal conclusions that have been deduced from it, also their bearing upon different problems in physics and chemistry.

C. G. F.

The mean maximal deviation in the Brownian molecular movement and Brillouin's diffusion experiments. M. v. SMOLUCHOWSKI. *Sitzb. Akad. Wiss. Wien Abt. IIa* 124, 263-76(1915).—A probability calcn. applicable to mol. displacement in the Brownian movement. Brillouin's deductions (*C. A.* 7, 3870) are criticized on the ground that he assumes that particles striking the sticky wall of the vessel adhere without chance of return, and that there is no increase of viscosity in the liquid layer adjoining the wall. The two erroneous assumptions compensate.

G. L. W.

A study of the form of the ultramicroscopic particles in colloidal solutions of metals. R. GANS. *Publicaciones univ. nacional de la Plata, facultad de ciencias fis. mat. y astron.* 1915, No. 16, 161-79.—The measurement of the absorption curve of colloidal solns. of Au and Ag is a very sensitive method for detg. the form of the ultramicroscopic particles. The results in the case of these 2 substances showed very accurately

that their form is spherical. The supposition of Siedentopf and Zsigmondy that the particles have the form of disks or platelets is entirely untenable. D. I. MACHT.

The dissociation equilibrium $2\text{NO} + \text{Cl}_2 \rightleftharpoons 2\text{NOCl}$. A confirmation of the hypothesis of the additivity of the internal atomic heats. MAX TRAUTZ AND CLAUS F. HINCK. Heidelberg. *Z. anorg. allgem. Chem.* 93, 177-201(1915).—A discussion of the existing data on the above equil. and its bearing on the hypothesis of the additivity of the internal atomic heats (*C. A.* 8, 452). The reaction isochor is integrated both with the aid of Nernst's theorem, using existing data for specific heats, and by the aid of T.'s hypothesis of additivity of at. heats, and the theoretical values compared with the observed results of Vágó, Hinck, and Trautz. A critical discussion of the work of the above experimenters brings out the fact that over a considerable range values obtained by different observers by different methods in the temp. interval 450-600° abs. show excellent agreement with each other and are uniformly about one-half of the theoretical values calcd. on the basis of additivity. Above 600° abs. the exptl. values begin to diverge from the theoretical, probably due to a side reaction. Comparison with theoretical values calcd. on the basis of non-additivity, however, shows the observed values to be 50-160 times larger. It is concluded that the hypothesis of additivity of the at. heats is confirmed, the difference of 50% being explained by uncertainties in the constants. G. W. MOREY.

The resolving effect of nuclei on reduction in a mixture of aurichloric acid and hydrogen peroxide. ARNE WESTGREN. Upsala. *Z. anorg. allgem. Chem.* 93, 151-60(1915).—The fact that Zsigmondy's nuclei method for the estn. of the size of the particles of a dispersed phase has been found to give good results both with amicroscopic and submicroscopic colloids led to the testing of the effect on the size and concn. of the resulting colloid of varying the components. The size of the particles was detd. by application of Stokes' law, using the method previously described by W. (*C. A.* 9, 737). Variation of the amt. of H_2O_2 was without effect on the degree of dispersion of the colloid obtained, and the size of the added nuclei was also without effect. Variation in both the concn. of the added nuclei and the Au concn. of the soln. were without effect up to a certain limit, but when the soln. was too dil. spontaneous crystn. centers developed. G. W. MOREY.

Action of salts with water of hydration and without water of hydration on the velocity of saponification of esters. J. E. L. HOLMES AND HARRY C. JONES. *J. Am. Chem. Soc.* 38, 105-21(1916); also part of *Publ. Carnegie Inst. Washington* No. 230. —Previous spectro- and radiomicrometric work has shown that combined H_2O (H_2O of hydration) has a different power from free H_2O to absorb light; the present work shows that a similar chem. difference exists. The sapon. of MeOAc in 24 and 48 hrs. at 15°, 25° and 35° in 0.25, 0.5 and 1 *N* solns. of KCl , KNO_3 , NaCl , CaCl_2 , MgCl_2 , SrCl_2 , LiCl , $\text{Ca}(\text{NO}_3)_2$, NaNO_3 , NaBr , KBr , BaCl_2 , $\text{Mg}(\text{NO}_3)_2$, KI , NaI , CaBr_2 , MgSO_4 , $\text{Sr}(\text{NO}_3)_2$, LiBr , Li_2SO_4 , BaBr_2 , SrBr_2 and LiNO_3 was detd. (some expts. were also made with HCO_2Me), NH_4OH and corallin being used for the titrations. From the data, which are reproduced in tables and curves, H. and J. conclude that salts with H_2O of crystn. increase the velocity of sapon. more than salts with no H_2O of crystn.; on diln., the effect of the former salts decreases more rapidly than that of non-hydrated salts, showing that the result cannot be due to hydrolysis alone; the sapon. curves for the 2 esters are very similar; the large effect of hydrated salts is probably due, in part, to the combined H_2O being more highly ionized than free H_2O ; the amt. of sapon. seems to be due to the combined effect of both cation and anion; it is probable that anions as well as cations are somewhat hydrated; the hydration of cations is inversely proportional to their at. vols.; there seems to be a diln. of max. sapon. for each salt; hydrated salts show a large temp. coeff., probably due in part to hydrolysis, notwith-

standing the decompn. of hydrates with rise in temp.; decompn. of hydrates may play an important role in the increased velocity of chem. reactions with rise in temp.

CHAS. A. ROUILLER.

Studies of the imperfect crystals formed in a colloidal medium. ALBERT AND ALEXANDER MARY. *Bull. soc. Belge geol.* 26, 69-73(1912); *Neues Jahrb. Min. Geol.* 1915, I, Ref. 307-8.—The minute, more or less spherical cryst. masses of CaCO_3 , $\text{Ca}_3(\text{PO}_4)_2$, sulfates and fluorides of alk. earths, CuCO_3 , etc., formed in solns. of colloids such as $\text{SiO}_2 + \text{H}_2\text{O}$, albumin, oleic acid, and gelatin are described. The formation of these masses is discussed from the point of view of surface tension and capillarity phenomena, and it is found that their form is what would be predicted by theory.

E. T. W.

The reciprocal salt pair $\text{KCl} + \text{NaNO}_3 \rightleftharpoons \text{NaCl} + \text{KNO}_3$ and the manufacture of conversion saltpeter. W. REINDERS. Delft. *Z. anorg. allgem. Chem.* 93, 202-12 (1915).—The above reciprocal salt pair was studied by detg. isothermal soly. curves at 5, 25, 50 and 100° . The results, which are summarized by means of tables and curves, are too voluminous to be abstracted, but the main features of the system are the following. Over the entire temp. range $\text{NaCl} + \text{KNO}_3$ is the stable salt pair. The soln. in equil. with NaCl , NaNO_3 and KNO_3 is at all temps. congruently satd., but the soln. in equil. with NaCl , KCl and KNO_3 becomes incongruently satd. between 25 and 50° . At all temps. the soly. of NaNO_3 in H_2O is raised by addition of KNO_3 , which is to be ascribed, not to the formation of a double salt, but to the fact that the end point of the curve representing the equil. $\text{NaNO}_3 + \text{KNO}_3$ is the eutectic in the binary system, which is at the relatively low temp. of 218° . Various possible procedures in the manufacture of conversion saltpeter are discussed from the standpoint of theoretical yield, and it is shown that the best conversion is obtained by using an excess of NaNO_3 , which is in harmony with present technical practice, and that contamination by NaCl may be prevented by addition of H_2O at the proper point, which would obviate the necessity of the present method of washing out the admixed NaCl .

GEORGE W. MOREY.

Studies in the molecular theory on the reversion of thermodynamically irreversible processes and on the recurrence of abnormal conditions. M. v. SMOLUCHOWSKI. *Sitzb. Akad. Wiss. Wien, Abt. IIa* 124, 339-68(1915).—Probability calcns., intended to demonstrate theoretical reversibility for all processes, in accordance with molecular kinetics. Observed irreversibility is due to the length of the period of probable reversion. In the diffusion of O and N the return of a state in which the concn. of O is 1% in excess of normal occurs for a sphere of 1 cm. radius in 10^{10} sec., and for a sphere of 1.1×10^{-8} cm. radius in 10^{-11} sec. For visible vols. such a process seems irreversible while ultramicroscopically it is reversible or "revertible," i. e., automatically reversible.

G. L. WENDT.

The reversed heat engine as a drying machine. PAUL J. FOX. *J. Ind. Eng. Chem.* 7, 1065-9(1915).—The cycle suggested is that air is expanded adiabatically in a cylinder, warmed to atm. temp. in a heater (the source of heat being the atmosphere), and then compressed adiabatically in another heater. The cycle is discussed from a purely thermodynamic standpoint. It is calcd. that if air at 60°F . is warmed to 100°F . the air need only be expanded to 11.4 lbs. abs.; and the ratio of heat added to heat equivalent of work done will be 12.3 to 1, in other words, the cycle should have a far greater efficiency than most operations of heating as now carried on. There are many processes where a positive circulation of warm air at a definite temp. would be advantageous, e. g., drying products which are sensitive to heat. The expansion in the first stage of the cycle will in most cases cause a deposition of H_2O , so that the air will be dried by the process as well. A disadvantage is that for high efficiencies

the temp. lift should be small, and in case of widely fluctuating atm. temps. the result would be fluctuations of equal magnitude in the drying chamber. Means of circumventing this are given, such as changing the valve settings or having several machines in series and operating only as many as would be needed to give the required lift.

W. L. BADGER.

Decomposition potentials of fused alkali hydroxides. B. NEUMANN AND E. BERGVE. *Z. Elektrochem.* 21, 143-52 (1915); cf. *C. A.* 9, 3032.—Attempts to measure directly the potentials of Na against NaOH and K against KOH, as well as the cell $\text{Na} \mid \text{NaOH} \mid \text{KOH} \mid \text{K}$ were not very successful on account of exptl. difficulties. The decompn. potentials have been measured by LeBlanc's method (1902) for NaOH, KOH in the presence of air, NaOH in the presence of Na_2O_2 , KOH in an atm. of N, and mixts. of NaOH and KOH in both air and N. The following values for the decompn. potential were obtained:

NaOH.		KOH.	
Temp.	Decompn. potential.	Temp.	Decompn. potential.
180	2.38	...	..
200	2.32	200	2.4
230	2.29	230	2.37
280	2.25	280	2.34
305	2.25	305	2.36
335	2.22	335	2.4
390	2.05	380	2.25
450	1.87	...	..
530	1.62	530	1.8
640	1.32	...	..

The temp. coeff. above 335° for NaOH was 2.95×10^{-3} , for peroxide-free KOH 3.05×10^{-3} . The potential difference is therefore independent of the temp. The decompn. potential of LiOH gave no values for $\text{Li} \mid \text{LiOH}$, but a value of the order of the decompn. potential for H_2O .

E. B. MILLARD.

The electric field and the parallel arrangement of atoms and the polarization of the light emitted by them. Preliminary announcement. J. STARK. *Aachen. Naturwissenschaften* 3, 419 (1915).—S. found that the lines of the 3rd secondary series in the spectrum of Li are polarized by an intense elec. field in such a way that the parallel components of the lines (*i. e.*, those vibrating parallel to the elec. field) appear decidedly sharper and brighter than the components vibrating at right angles. This new phenomenon is here recorded for the first time. Another new and interesting observation is the following: Whereas the relative brightness of the main series, as compared with the 1st and 2nd secondary series of lines, is not appreciably effected by the elec. field, the relative brightness of the 3rd secondary series is most remarkably dependent upon the intensity of the elec. field. At low field intensities the 3rd secondary series is very faint (a photographic plate exposed long enough to record these faint lines is decidedly overexposed for even the second secondary series). At high field intensities the 3rd secondary series is very much brighter than the 2nd.

C. G. F.

The Kirchhoff radiation law. G. JÄGER. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 305-8 (1915).—The law is derived from thermal considerations, without the use of mathematics or hypothetical black and diathermic bodies or perfect reflectors.

G. L. WENDT.

Some observations on the absorption spectra of the vapors of inorganic salts. E. J. EVANS. *Univ. Manchester. Phil. Mag.* 31, 55-62 (1916).—The vapors of

NH_4Cl , HgCl , HgCl_2 , CdCl_2 , CdBr_2 and CdI_2 do not give well-defined absorption bands in the region λ 2500– λ 6700, as do Br and I. Excepting NH_4Cl , they give a general selective absorption in the ultraviolet, which is greater for CdI_2 and CdBr_2 than for CdCl_2 . Certain lines from CdCl_2 between λ 3000 and λ 3200 are intensified by the presence of H, so that an unstable compd. of Cd and H is suspected.

Measurements of the wave lengths on the international system in the red and infra-red arc spectra of the elements. II. J. M. EDER. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 101–21(1915); cf. C. A. 10, 146.—Red and infra-red lines are recorded for Al, Pb, Gd, Au, Cu, Nd, Pr, Ag, Tl, Y, and Zn.

G. L. WENDT.

Plates sensitized for spectrum photography in the infra-red, red, yellow and green. JOSEF M. EDER. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 231–40(1915); see C. A. 10, 157.

G. L. WENDT.

The magneton. P. WEISS. *Engineering* 100, 345–6(1915).—Lecture. Magnetism cannot be a property of the atom, since the Heusler alloys would then be non-magnetic. If this were the case it would be impossible, too, for cuprous salts to be diamagnetic and cupric salts paramagnetic. A diagram is shown illustrating the number of magnetons in alloys of Fe-Ni, Fe-Co and Ni-Co from 0 to 100%. There were sharp breaks in the curves corresponding to the definite compds. Fe_3Co and Fe_2Ni . The detns. of the number of magnetons indicated a new form of Fe, and it appears as if the atoms of an element might have different magneton values. Electromagnets could be strengthened by fitting them with pole tips of Fe-Co alloy. Langevin's law does not hold for Fe alloys at temps. above that at which they almost lose their magnetism (Curie point). W. could offer no explanation for the fact that his magneton was 18.5×10^{-21} while the nuclear theory of Bohr and Rutherford demands 5 times that value, 92.7×10^{-21} . He also was troubled about the fractional values for the magneton. In Cu salts, e. g., the magneton number in all concns. was 9.62, and that for Mn 29.2. Other difficulties, such as the half-magneton values, could be met by multiplying through by 2, but not those for Cu and Mn.

E. B. MILLARD.

The correction for the projecting thread of a mercury thermometer in a cooler atmosphere. GOTTFRIED DIMMER. Imper. Commission of Standards, Vienna. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 141–6(1915).—Numerous expts. have been made both in an atm. of 20° and one of 4° which verify the Kopp formula for the correction for the projecting thread, viz., $k = n\alpha(t_1 - t_2)$, where n is the number of projecting degrees on the thermometer, α is the apparent coeff. of expansion of Hg in the glass, t_1 is the temp. read, and t_2 is the temp. of an auxiliary thermometer half-way up the exposed thread. In the absence of air currents the formula is entirely reliable up to $t_1 = 400^\circ$. Cf. C. A. 8, 3743.

G. L. WENDT.

The correction for the projecting thread of a mercury thermometer exposed to air currents. GOTTFRIED DIMMER. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 124, 241–7(1915); cf. preceding abstract.—The disturbances due to air currents may be entirely obviated by using a strong, wide horizontal blast of air blowing equally on the precision thermometer and on the auxiliary one. Experiments in which $t_2 - t_1$ varied from 70° to 326° showed exact correspondence with the Kopp formula under these conditions.

G. L. WENDT.

The rare gases of fire-damp. CHARLES MOUREU AND ADOLPHE LEPAPE. *Ann. chim.* 3, 137–57(1915).—A general and historical discussion, including some analytical results, and a restatement of M.'s astrophysical theory. Cf. C. A. 6, 1120, 2720; 8, 1699, 2239, 3358.

The necessity for a unit scale of hardness in Röntgen ray technic. P. LUDWIG. Freiberg i. Sa. *Naturwissenschaften* 3, 403-7(1915).—A discussion of the 9 units in common use and the practicability of adopting the abs. wave-length scale. The election of a commission of Röntgen ray physicists is urged to choose a suitable standard scale of units.

G. L. WENDT.

The process for stabilizing the functioning of Röntgen tubes by the absorption of carbon dioxide. P. CARDANI. Univ. Parma. *Atti accad. Lincei* 24, I, 898-904 (1915).—In a preceding note (cf. *C. A.* 9, 2188) C. showed how Röntgen tubes obtained from the factories when opened and connected with a pump and a manometer evolved notable amts. of gas which diminished in amt. with time, but which was evolved in notable amts. again when the tubes were excited after a period of rest. The gas emitted was not air nor combinations of the gases of the air. The tubes were heated to 400° and an attempt was made to accelerate the emission of gas by passage of the discharge and the action of a Gaede pump. It was found that the gas in the tubes was not re-absorbed and that after a prolonged evacuation the pressure was elevated in 4 days from 0.052 to 0.226 mm. on exciting the tubes a few mins. at a time at intervals of some hrs. The appearance of the tube had undergone a marked change. At the beginning at 0.226 mm. the light invading the tube was bluish white and the cathode stream white, but the diffuse light became a magnificent sea-green and the cathode rose-red. The cathode at first emitted another gas but under the evacuation treatment it finally yielded only H as shown by its spectrum. C. made expts. to see if it was possible to construct Röntgen tubes by subjecting the Al electrodes to a long exhaustion. He thought that it would be advantageous first to sat. the electrodes with some other gas which would impede the emission of H. Among the gases easily absorbed was CO₂ which is quickly dissociated, when the tube is excited, into CO + O, of which O is first absorbed and CO more slowly. The appearance of the tube on excitation when it contained CO was the same as in the first stage described above. If then in the construction of Röntgen tubes the emission of H by the Al electrodes is eliminated by satg. the electrodes with CO, it is clear that on subjecting tubes thus treated to heating and simultaneous excitation the gas 1st evolved would be CO, then CO + H and finally H alone. This was verified and proved by the spectra. It was thus shown that by eliminating the air adhering to the surface of the electrodes the gas emitted is solely CO at first and solely H at the end. The expts. were continued in order to find conditions under which the emission of H could be prevented. After several trials (described) the tube was evacuated as much as possible and filled with CO₂ under pressure and the discharge was passed (anticathode isolated). The results indicate that the air adhering to the electrodes was released before the absorption of CO took place. Tubes prepared in this way began to develop X-rays as shown by the electrometer at 0.033 mm. and the evolution was very abundant at 0.020 so that the

needle was deviated 80 divisions in 5 secs. by the charge carried by the ions produced by the X-radiation. The expts. are being continued. E. J. WITZEMANN.

The magnetic constants of isotopic substances. STEFAN MEYER. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, Abt. IIa* 124, 187-92(1915).—Specimens of Hönigschmid's pure Ra G salts (*C. A.* 9, 3026) when tested in the Fe-free magnetic balance gave values for the magnetic susceptibility within 1% of those for pure ordinary Pb salts. This indicates that at. magnetism is a property due to the electron rings rather than to the nucleus, assuming the Rutherford-Bohr atom. That it is usually an additive property of the atom, however, indicated that it is seated in one of the inner electron rings. G. L. WENDT.

The interchange of atoms between solid and liquid phases. G. v. HEVESY. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, Abt. IIa* 124, 131-9(1915); see *C. A.* 9, 2485. G. L. WENDT.

The atomic volume curve and the connection between atomic volumes and radioactivity. STEFAN MEYER. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, Abt. IIa* 124, 249-62(1915).—A new at. vol. curve is drawn, for which the at. numbers of the elements as given by Moseley (*C. A.* 8, 2307), instead of the at. wts., are divided by the densities. There are then abrupt breaks in the curve between N and O, P and S, and less marked breaks at the corresponding points of the longer periods, i. e., Ge-As, In-Sn and Tl-Pb. It is pointed out that these positions are those at which the number of rings of electrons in the atom increases by one, according to the theory of Bohr (*C. A.* 7, 3712). As long as the number of rings remains const. an increase in the number of electrons in the outermost ring, corresponding with an increase in valence, results in a decrease in the at. vol., and an increase in the latter follows a decrease in the former. The abrupt change at P may be connected with the 2 allotropic forms of P and both densities may be used; then red P has the greater at. vol. and probably is the trivalent form with 3 electronic rings, while white P has a lesser vol., is pentavalent, and has but 2 electron rings. A similar allotropy may occur with N, As, etc., but in the heavier atoms the effect is relatively smaller. That not only high at. wt. but also great at. vol. cause at. instability is shown by the radioactivity of K and Rb. That Cs is not radioactive and that the rays from Rb are weaker than the K rays results from the lesser at. vol. gradient for K-Rb-Cs as compared with that for Li-Na-K. In the radioactive disintegration series the at. vols. attain and pass a max. value but never pass a minimum. An α -ray product formed with increased at. vol. has a shorter period than its parent, but if the resulting at. vol. is less the period is greater. In the interval of increasing at. vol. the return of a disintegration series to an isotope (as U_1 to U_2) involves a shortening of the period, but after the emanations are passed and at. vols. are decreasing such a return (as Ra B to Ra D to Ra G) increases the period. Of 2 successive β -radiators the 2nd always has the lesser period. Such β -ray interruptions in a series of α -ray changes occur at U X_1 and the "B" elements, all of which are in the 4th group of the periodic table where the at. vol. is at a minimum. Branching of the disintegration series occurs only at the "C" members, which are in the 5th group and therefore correspond with P and N. It is suggested that there are present 2 allotropic modifications of the C elements, resp., tri- and penta-valent, of which the former contains one additional electronic ring, as in the case of N and P, and that the 2 modifications disintegrate in different manner, one giving a β -, the other an α -ray. G. L. WENDT.

The structure of gamma rays on the basis of the electro-magnetic theory of light. JAKOB KUNZ. Univ. Illinois. *Phys. Rev.* [2] 6, 413-8(1915).—Calcns. on the distribution of the energy radiated by an electron in collision. At low velocities the energy

radiates in an equatorial plane perpendicular to the line of motion but with increasing velocity the direction of radiation approaches the direction of motion of the electron, until, when the velocity of light is reached, the directions are identical. If the electromagnetic field is endowed not only with energy but with mass and momentum, then the electromagnetic mass of the electron, when it comes to rest, is thrown forward more and more with increasing velocity. The conception resembles then the old notion of light particles.

G. L. WENDT.

Absorption of the beta particles from some of the radioactive substances by air and carbon dioxide. ALOIS F. KOVARIK. Univ. Minnesota. *Phys. Rev.* [2] 6, 419-25(1915).—The ionization produced by β -rays in a shallow ionization chamber placed at a fixed distance from the source within a high-pressure vessel was measured at various pressures, and the coeff. of absorption thence calcd. The absorption curves in air and CO_2 are of the same shape as those in Al. The following values of the absorption per cm. for the β -rays from the following elements were obtained for air and for CO_2 , resp., at 1 atm. and 22°: Ra D, 0.097 and 0.183; Ra D (very soft), 0.64 and 1.69; Ra E, 0.0152 and 0.0297; Th B, 0.090 and 0.142; Th C + Th D, 0.0068 and 0.0129; Act B, 0.31; Act C + Act D, 0.0091 and 0.0175; U X_1 , 0.12 and 0.23; U X_2 , 0.0063 and 0.0114. To compare the relative ionizations of the soft and hard rays when both are present, ionization ratios were detd. as follows for the β -rays from the following sources: Ra D (soft) to Ra E, 2.4; Ra D (harder) to Ra E, 0.30; Act active deposit, soft to hard, 1.14; and Th active deposit, soft to hard, 2.86. These values are for air at 1 atm., and were computed by extrapolation to zero absorber.

G. L. WENDT.

Distribution of transmitted and reflected beta particles determined by the statistical method. ALOIS F. KOVARIK AND L. W. MCKEEHAN. Univ. Minnesota. *Phys. Rev.* [2] 6, 426-36(1915).—An adaptation of Geiger's counting method was used to det. the number of β -particles reflected from and transmitted through an Al plate at all angles. The data accord with Rutherford's theory of scattering by single at. encounters. The mean free path of the β -particle in Al between deflections is deduced as 0.001 cm. When the plate is thick enough to deflect practically each particle a number of times the transmitted rays emerge in accordance with a cosine law, as do light waves emitted from a heated solid.

G. L. WENDT.

An attempt to influence the rate of radioactive transformations by means of alpha rays. JEAN DANYSZ AND LOUIS WERTENSTEIN. *Compt. rend.* 161, 784-7(1915).—Although no chem. or physical agency is known which has any effect on the rate of transformation of the radioelements, it was nevertheless thought that if some agency could be made to act upon the nucleus of the atom within which, according to Rutherford's theory, is inherent the property of radioactivity of an element, an artificial alteration in the rate of transformation might be possible of attainment. Such an agency is available in the case of α -rays, for when an element is bombarded by these rays a certain small percentage of the rays undergoes total reflection in the absorbing material, which phenomenon is caused, according to theory, by these α -particles coming within the influence of the nucleus of the atom. Any change in the rate of transformation would be more marked in the case where a long-lived element changes into a short-lived one, as in the transformation of $\text{U}_1 \rightarrow \text{U X}_1$, and of Meso-Th $\rightarrow$ Meso-Th $_2$. A layer of U_2O_8 just thick enough to absorb the α -rays was accordingly exposed to the rays from 18 millicuries of Ra E, for 6 days, and the activity measured before and after exposure to the rays. A Meso-Th prepn. was likewise exposed to the rays in the same way. From the negative results obtained it is concluded with a considerable degree of certainty that even those α -particles which come under the influence of the nucleus of the atom do not have any effect in changing its rate of transformation.

W. H. ROSS.

Work of the Physikalisch-Technische Reichsanstalt in 1914 2.

Extracting vanadium, uranium and radium from ores. R. B. MOORE. U. S., 1,165,692, Dec. 28. (Dedicated for free use by the public.) Ores containing V, U and Ra are leached with a soln. of Na_2CO_3 and NaOH. V is recovered from the soln., and the residue is leached with HCl or HNO_3 , and U and Ra are recovered from the soln. thus formed. Stronger acid may be applied to the residue for extg. any V still remaining in it.

Extracting vanadium, uranium and radium from ores. R. B. MOORE. U. S., 1,165,693, Dec. 28. Ra ores which may also contain V, U and Fe are leached with hot HCl or HNO_3 , and BaCl_2 and H_2SO_4 are added to the soln. obtained to ppt. BaSO_4 together with RaSO_4 . NaOH or KOH is added to the remaining soln. to ppt. U and Fe together with any Ra still remaining in soln. and then the V is pptd. from the soln. as Fe, Cu, Pb or Ba vanadate. The ppt. containing U, Fe and Ra is treated with dil. H_2SO_4 or HCl and BaCl_2 to dissolve U and Fe and the soln. of U and Fe is boiled with an excess of Na_2CO_3 , the Fe is pptd. and the U subsequently pptd. with NaOH. Na_2CO_3 may, if desired, be used instead of NaOH or KOH for the first alkali pptn. in which case Fe, Al and Ra with some of the U and V will be pptd. This ppt. is treated in the same manner as that obtained with NaOH and the U and V are successively pptd. from the remaining soln.

4. ELECTROCHEMISTRY.

Michael Faraday. ERNST JENTSCH. *Naturwissenschaften* 3, 625, 640(1915).—Biographical. C. G. F.

The Vigeland aluminium factories near Venneala, Norway. J. REYVAL. *Lumiere elec.* 30, 298-303; 31, 8-14(1915).—R. describes in detail the water power development and the elec. installation. There are 3 generators each feeding 35 Al furnaces. The voltage per furnace is 7. The capacity of the plant is 2000 tons Al per annum. Details of manuf. are withheld. W. H. BOYNTON.

The electrolytic preparation of hydrogen and oxygen. YOGORO KATO. *J. Chem. Ind. Japan* 18, 919-33(1915).—The diaphragms used in the commercial production of H and O do not keep these gases completely separate as shown by diffusion data given by K. He finds that pure gases can be technically prepared without the use of a diaphragm. Special electrodes are employed; these have an inclined active surface to which the generated gas adheres by reason of its buoyancy and accordingly does not diffuse into the soln. C. G. F.

A new electrolytic cell for making pure oxygen and hydrogen. ANON. *Met. Chem. Eng.* 14, 108-10(1916); illus.—The International Oxygen Co. of New York has introduced a new style of O and H generator under the name "I. O. C. bipolar generator." This is based on patents of Moritz and Levin (cf. C. A. 8, 301, 2118). In outward appearance the new generator resembles a filter press. There is a series of metallic plates (bipolar electrodes) clamped together in a heavy frame, electrically insulated from one another by diaphragms of porous asbestos fabric. Each pair of these electrodes forms a closed cell. The electrolyte is KOH. The mingling of the O and H in each cell or compartment is prevented by the diaphragm, which while permitting the passage of the soln. resists the passage of the gases. As the gases pass upwards and thence through the off-takes, H_2O is automatically added from a supply tank. The anode side of the electrodes is heavily Ni-plated and the cathode side is of com-

mercially pure Fe. This metal combination has been found materially to facilitate the decompn. of the H_2O due to lower overvoltage as compared to older types of electrodes. Other details of construction and operation are described in full. The demand for H has materially increased within recent years. O finds a wide application in welding practice ($O-C_2H_2$ and $O-H$ welding). C. G. F.

Polarization in LeClanché cells. D. A. MACINNIS. *Trans. Am. Electrochem. Soc.* 29 (advance copy) (1916).—Thompson and Crocker (*C. A.* 9, 756) concluded from their expts. that pyrolusite combines quantitatively with the H evolved and that the only substance to which the polarization of these cells can be attributed is NH_3 . MacI. contends that it is partly H since the formation of free NH_3 is insufficient to account for polarization of the order of 0.5 v. or more since the NH_3 concn. can hardly exceed 5% even momentarily. His contention is based upon e. m. f. measurements and theoretical considerations. H will be evolved at the cathode only when its pressure reaches 1 atm. The action of the MnO_2 is to keep its pressure far below this. The system $MnO_2-Mn_2O_3-H_2-H_2O$ is univariant; under equil. conditions the system will have a definite though very small H pressure for each temp. If allowed to stand on open circuit the + electrode of the LeC. cell will reach a voltage corresponding to the soln. tension of H at this equil. pressure. MacI. regards the cell as a double one: $Z | NH_4Cl + ZnCl_2 | H_2, 1 \text{ atm.} - H_2, 1 \text{ atm.} | NH_4Cl + ZnCl_2 | H_2, x \text{ atm.}$ He measured the e. m. f. of the left half of this double cell at 25° and found -0.514 v. The e. m. f. of the right is taken as -0.986 v. ; assuming that the e. m. f. of the LeC. cell on open circuit has the av. value -1.50 v. ($-1.50 + 0.514 = -0.986$). With the aid of Nernst's equation x is then found to be $4 \times 10^{-24} \text{ atm.}$ which equals the pressure of H on the cathode at equil. on open circuit. A drop in voltage from -1.50 to -1.20 corresponds to a rise in the H pressure from 4×10^{-24} to 10^{-24} atm. C. G. F.

Electrostatic effects upon a cell with insulating walls and a liquid core. I. MALCOLM. *Compt. rend.* 161, 694-6(1915).—The dielec. properties of liquids in an electrostatic field were studied by placing the liquid in a small quartz cell located between the plates of a condenser. Preliminary work showed fused quartz to be a better insulator than crystalline quartz. The dielec. const. for fused quartz, $k = 4.86$. Upon charge or discharge, no residual effect could be detected with the empty cell alone between the condenser plates; neither was any such effect apparent when the cell was filled with H_2O or Hg. When, however, the cell was filled with an "insulating" liquid such as vaseline, turpentine, or petroleum ether, the equil. upon charge or discharge was not attained instantly (no data given). These facts may be explained by assuming the ionic particles in H_2O and Hg to have extreme mobility, while in the case of the other liquids, the ions only recombine slowly after the sepn. due to the elec. charge. M. has already detd. the cond. of certain highly non-conducting liquids in ozocerite cells. The use of the quartz cell will allow the method to be extended to all liquids.

F. A. STRAUSS.

The dimensions of the units of electrical measurement. H. MAURER. Berlin. *Elektrotechn. Z.* 19, 228-30(1915).—At present the differences between the electrostatic units and the electromagnetic units of measurement are the cause of much confusion. This difference has arisen through a mathematical misinterpretation of the factor l in Coulomb's equation for electrostatic attraction. Through this misinterpretation, the force of attraction between two charges of electricity (F) has been assigned the dimensions ($m. l t^{-2}$) where m = mass, l = distance, and t = time. Newton's law, which has been correctly interpreted and used in most electrostatic work, assigns the dimensions ($m^{-1} l^2 t^{-2}$) to F . Although the values derived by the misinterpretation of Coulomb's law can easily be shown to be incorrect, they have been generally accepted and applied in electromagnetic work. Therefore in order to avoid confusion, M. pro-

poses that the units, hitherto used solely for electromagnetic measurements, be used in electrostatic work as well. The values of the present electrostatic units are calcd. and given in terms of electromagnetic units as well as in c. g. s. units. The values of the commoner units are:

	Electrostatic.	Electromagnetic.
1 Coulomb =	10^{-1} c. g. s. units	3×10^9 c. g. s. units
1 Volt =	10^8 "	0.00333 "
1 Farad =	10^{-9} "	9×10^{11} "

F. A. STRAUSS.

Galvanic battery. M. L. KAPLAN. U. S., 1,166,414 Dec. 28. Acid manganous polymanganite is used as depolarizing agent in a battery of the LeClanche type. Cf. C. A. 10, 154.

Electric dry battery. H. WILHELM and H. OLANETA. U. S., 1,166,871, Jan. 4. Structural features.

Electrolytic recovery of copper, zinc, or nickel. N. V. HYBINETTE. Ger., 285,652, Nov. 8, 1912. The initial material, which contains the metals partly as oxides and partly as sulfides, is subjected to extn. and electrolysis in 2 steps, extg. first with a soln. not too rich in $\text{Fe}_2(\text{SO}_4)_3$ and electrolyzing the resulting ext. without diaphragms, and then employing a soln. relatively rich in $\text{Fe}_2(\text{SO}_4)_3$, and electrolytic cells with diaphragms. From the cells without diaphragms a portion of the liquor is subjected, in a 2nd phase, to the action of electrolytic cells with diaphragms, with increase of the $\text{Fe}_2(\text{SO}_4)_3$ content, and then used for further extn. of the residual difficultly sol. metal constituents. E. g., if a sulfidic ore containing about 4% Cu is to be worked, the crude material is roasted until 0.5-1% S remains unoxidized, and then extd. and electrolyzed.

Purifying electrolytic chlorine. U. ISHIKAWA. U. S., 1,166,524, Jan. 4. H present in electrolytic Cl is caused to react with Cl to form HCl, by the catalytic action of Pt, Au, Fe, Ni, Co, Cr or Cu, and the HCl thus formed is oxidized by the action of peroxides or oxidizing salts to form Cl and H_2O . MnO_2 may be used to serve both as catalyst and oxidizer, thus carrying out the process in a single step.

Tungsten lamps. A. J. LIEBMANN. U. S., 1,166,464, Jan. 4. Defective W filaments in incandescent lamps are restored to good condition by volatilizing BaF_2 within the lamp at a temp. above the usual working temp. of the filament. W fluoride is formed and this decomposes in contact with the portions of the filament which are excessively heated because of defective condition or thinness. The vacuum within the lamp is restored to its normal condition by the second reaction. Other halogen salts of alkali or alk. earth metals or Tl may be used.

Electric incandescent lamp. S. BUXBAUM. Ger., 285,964, May 2, 1914. The filaments are arranged cross-wise, but sepd., in such manner as to give the appearance of a net.

Portable electric lamp. F. SCHIKORR and G. WOLFF. Ger., 285,880, Oct. 31, 1914.

Vacuum tubes. A. LEDERER. Brit., 17,646, July 25, 1914. The small quantity of one or more alkali metals, enclosed in a lamp containing gases such as Ne, He, A, or Kr, as described in 17,036 (C. A. 10, 157) is now confined, say in the form of a deposit, to the neighborhood of the electrodes or of the anode only.

Electric endosmosis; tanning; dyeing. GES. FÜR ELEKTRO-OSMOSE. Brit., 19,849, Sept. 16, 1914. Solid bodies, and liquids for impregnating them, are subjected to elec. current between diaphragms of such character as to retain the active constit-

uents while preferably allowing the escape of impurities such as acids and bases. The process is applicable to tanning, dyeing, and other cases of adsorption. App. is specified.

5. PHOTOGRAPHY.

LOUIS DERR.

Advances in scientific photography. E. SCHLOEMANN. *Z. wiss. phot.* 15, 55-64, 78-96(1916).—Bibliography for 1914. L. DERR.

The pulverizing action of light, with especial reference to photographic problems. H. NORDENSON. *Z. wiss. phot.* 15, 1-17(1916).—There is no pulverizing effect with metals, either in vacuum or in gases. With sheet metals, in certain cases colloid formation takes place, but it is only chemical. With non-metals, in a certain few cases a change of structure appears, most readily explicable on chemical grounds. Thus a true pulverizing by light does not exist. In the usual photographic film, changes of structure by light-action are not definitely established, and are unconvincing under observation. Explanations of the latent image based on this phenomenon are therefore to be discarded. L. DERR.

The pulverizing of silver halides by light. H. LÜPPO-CRAMER. *Z. wiss. phot.* 15, 125-32(1916); cf. preceding abstract.—Even though direct pulverizing of Ag halide by light is held to be impossible, it may be assumed that splitting off the halogen effects a physical disintegration of the halide, and thus may be the cause of the increased soly. and the definitely proved increased degree of dispersion. L. DERR.

Use of potassium ferrocyanide for increasing the light-resistance of photographic silver compounds. N. SULZBERGER. *Atelier Phot.* 22, 45-7(1915).—When $K_4Fe(CN)_6$ is used as a fixer, the nature of the effect is as yet undetermined, but is certainly not like that of hypo, because compds. soluble in hypo are left in the film. The salt is effective for gas-light and printing-out papers, and requires a minimum time as compared with hypo because the long final washing is unnecessary. The image on Aristo paper is bleached by $(NH_4)_4Fe(CN)_6$, but is restored by development with rodinal, and is then light-resisting. L. DERR.

Stripping of gelatin dry plates. S. M. FURNALD. *J. Frank. Inst.* 181, 141(1916).—For stripping films from large plates, the following is recommended: flow the plates with a mixt. of collodion 30 cc., and glycerol 2 cc., and as soon as the collodion has set, cut around the portion to be stripped with a knife and immerse the plate in 4% NaF 2 parts, formalin 1 part. In about 1 min. the film can be removed. The collodion is not needed for small plates. L. DERR.

A contribution to the explanation of the formation of the latent image on exposing the photographic silver bromide plate. R. FORMHAUS. *Chem. Ztg.* 39, 917(1915).—F. supposes that the AgBr exists in the gelatin in a completely undissociated state; that light, assisted by H_2O in the gelatin, causes dissociation, and that the developer affects the dissociated salt only. Cf. *C. A.* 1, 2978; 2, 1392; 5, 1703, 3016; 6, 38, 3063; 7, 1681; 9, 2355, 2490. J. H. MOORE.

Production of duplicate negatives, methods of image reversal, lateral inversion and stripping. E. STENGER. *Z. Reprodukt.* 17, 70-2, 78-80, 86-7, 94-5(1915); cf. *C. A.* 9, 3036.—Detailed working instructions for a negative-duplicating process in which a AgBr gelatin dry plate is dichromated; exposed under the negative to be copied, slightly fogged, and developed. If the dichromate is washed out before developing, the gradation obtained is steeper than if it is not washed out, and may even exceed the normal. L. DERR.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Water of crystallization. Compounds with $2\text{H}_2\text{O}$. II. I. GUARRESCHI. Univ. Turin. *Atti accad. sci. Torino* 50, 881-902 (1915).—G. continues the report on the salts with $2\text{H}_2\text{O}$ of crystn. (cf. C. A. 9, 417). The purpose was to establish the temp. of dehydration and to see which ones follow Rosenstiehl's rule, *i. e.*, lose the $2\text{H}_2\text{O}$ mols. simultaneously. The following salts are discussed in this paper: $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, $\text{Na}_2[\text{Fe}(\text{NO})(\text{CN})_5] \cdot 2\text{H}_2\text{O}$, $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$, $\text{NaBr} \cdot 2\text{H}_2\text{O}$, $\text{NaI} \cdot 2\text{H}_2\text{O}$, $\text{Cd}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$, potassium ethylidene disulfate, $\text{MeCH}(\text{SO}_3\text{K})_2 \cdot 2\text{H}_2\text{O}$, $\text{Na}_2\text{S}_2\text{O}_8 \cdot 2\text{H}_2\text{O}$, $\text{BaS}_2\text{O}_8 \cdot 2\text{H}_2\text{O}$. *Calcium sulfate*. Much work has been done on the dehydration of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, part of which G. reviews in detail, giving references. He finds that the data are discordant but it seems that the temp. at which $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ eliminates all or part of its H_2O varies with the conditions. Consequently exptl. work was undertaken by G. to det. the conditions for the easiest elimination of H_2O . Pptd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ lost no H_2O over CaCl_2 or H_2SO_4 even at 40 mm. pressure at $22-3^\circ$. After 3 hrs. in a steam oven at 99° it lost 0.3%, after 16 hrs. at 108° in an oven heated with toluene it lost 19.73% H_2O , and after 3 hrs. more in an amyl alc. oven no further loss occurred. After 5 hrs. more at $195-205^\circ$ the total loss was 20.6%. Under these conditions $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$ is not formed. Finely crystd. natural gypsum from Caltanisetta lost no H_2O over CaCl_2 , but heated directly at 99° for 2.5 hrs., it lost 16.15% H_2O (15.7% for 1.5 H_2O); after 10 hrs. more at 99° it had lost 19.7%. Gypsum from Moncucco, heated 2 hrs. at 99° , lost 14.8%; after 2 hrs. more the total loss was 15.36%; 8 hrs. more made it 18.8% (1.75 mol. H_2O 18.4%). Pptd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ lost about 0.4% H_2O in 2.3 hrs. at 99° ; in 19 hrs. at 108° it had lost 18.9% H_2O . Natural gypsum (marienglas) heated 1 hr. at $98-9^\circ$, lost 9.1% H_2O (1 mol. = 10.45%); after 2.5 hrs. the loss was 15.99%; after 10 hrs. it was 19.98%; after 2-3 hrs. at 108° no more wt. was lost. No true point of arrest was observed, but there is a great slowing up of the loss after 1.5 H_2O has been lost. The natural gypsum loses a large portion of its H_2O easily in the 1st hr., while the pptd. prepn. begins to lose it rapidly only after the 2nd or 3rd hr. Gypsum crystals from Moncucco heated 3 hrs. at $98.5-99^\circ$ lost 14.83% H_2O ; after 2 hrs. more the loss was 16.1% H_2O . Pptd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ under the same conditions lost about 0.5% H_2O in 3 hrs., 5.8% after 2.5 hrs. more, 16.4% after 6 hrs. more, etc. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ (marienglas) in an oven heated with heptane vapor ($93-4^\circ$) lost 5.7% H_2O after 1.5 hrs.; after 6 hrs. more 15.68% and after 14 hrs. more, 19.8%; no more was lost at this temp.; no point of arrest was noted. Pptd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ heated at $98-9^\circ$ in a current of air lost 12.7% H_2O in 3 hrs., and after 3 hrs. more the loss was 19.3%; another 3 hrs. brought it to 20.25%. The pptd. prepn. heated 2 hrs. in a current of dry air lost 0.54% H_2O in 2 hrs., 9.7% in 3 hrs. more, and 20.4% in 14 hrs. more. Gypsum from Moncucco kept for 2 hrs. in current of dry air at 99° lost 9.49% H_2O ; in 16 hrs. more the loss was 20.39% H_2O . The same substance heated at $98-9^\circ$ in air, dried with CaCl_2 , H_2SO_4 , soda-lime, etc., lost 14.9% H_2O in 1.25 hrs.; after 2 hrs. more the loss was 20.5%; after 4 hrs. more the loss was 20.88%. In the 1st hr. it lost nearly 1.5 H_2O and after 4-5 hrs. more it lost the other 0.5 H_2O . This anhydrous CaSO_4 absorbs 7.95% H_2O (6.6% = 0.5 H_2O) from the air in 24 hrs. Pptd. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ heated in desiccated air at 42° , 60° , 64° and 72° lost no wt. but after 6 hrs. at $81-2^\circ$ (b. p. of $\text{C}_2\text{H}_4\text{Cl}_2$) it lost 4.8% H_2O ; after 14 hrs. more it had lost 20.26%; after 4 hrs. at 125° it had lost 20.58%. When heated in a current of dry air there is no point of arrest.

All the H_2O is eliminated, the last 0.5 mol. more slowly than the rest. The dehydration point may be $81-2^\circ$. 1.0022 g. of the pptd. prepn. in a desiccator (over H_2SO_4 or better over P_2O_5) was placed in a thermostat for 24 hrs. at 30° , 40° , 50° , 60° and 70° , resp., with a total loss of 0.004 g. but at 80° in 20 hrs., it lost 11.3% H_2O ; after 20 hrs. more the loss was 20.08%; after 24 hrs. more the loss was 20.3%. Natural gypsum heated 65 hrs. at 72° in a desiccator lost 17.9% H_2O ; after 48 hrs. more the loss was 20.04%; after 48 hrs. more it was 20.25%. In neither case was the semihydrate observed as an intermediate product. The above expts. show that $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ loses nearly all its H_2O at $81-2^\circ$ and more easily at $98-9^\circ$, which is contradictory to the statement that at 130° it still retains 0.5 H_2O . The last small portion of H_2O is eliminated very slowly but 20-20.5% may be eliminated under the above conditions in 3-4 hrs. These results agree in principle with those of Plessy (*Compt. rend.* 24, 658, 812 (1847)) who found that gypsum loses all its H_2O at $110-5^\circ$ in a current of dry H_2 . There are no facts at hand as yet that det. whether the semihydrate is $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$, $2\text{CaSO}_4 \cdot \text{H}_2\text{O}$ or $\text{Ca}_2\text{S}_2\text{O}_6 \cdot \text{H}_2\text{O}$. G. prefers the latter. He considers that gypsum may be (I)

and that 2 mols. by the loss of $3\text{H}_2\text{O}$ give (II) as in the case of $\text{Cu}_2\text{S}_2\text{O}_6 \cdot \text{H}_2\text{O}$. And perhaps gypsum or cryst. $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ is really $\text{Ca}_2\text{S}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$. *Sodium nitroprusside*. Playfair (*Roy. Soc. London* 74, 328(1850)) stated that $\text{Na}_2[\text{Fe}(\text{NO})(\text{CN})_5] \cdot 2\text{H}_2\text{O}$, (a), loses no H_2O at 100° . Similar salts of Ba, Cu and NH_4 lose their H_2O at 100° . The exptl. work of G. shows that (a) loses no H_2O in a desiccator over H_2SO_4 if left for 18 hrs. When (a) is heated to 108° it loses its water rapidly; at $98-9^\circ$ the H_2O is lost rapidly, the last $\frac{1}{2}$ mol. requiring more time for its elimination than the first $1\frac{1}{2}$ mols. The fact that the last 0.5 mol. H_2O is lost with difficulty suggests that (a) should also have the double formula $[\text{Na}_2\text{Fe}(\text{NO})(\text{CN})_5]_2 \cdot 4\text{H}_2\text{O}$. At $15-17^\circ$ the anhydrous salt absorbs $2\text{H}_2\text{O}$ from the air. *Cupric chloride*. The earlier work is reviewed and references given. G. himself found that $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ lost 18.9% H_2O in 15 hrs. at 10 mm. over H_2SO_4 at $23-4^\circ$; in 30 hrs. more it had lost 20.76% and then lost no more; no HCl was lost. At 15° and 10 mm. it lost 10.21% (1 mol. = 10.55%) in 27 hrs. and the 2nd mol. (total 21.24%) in 87 hrs. more. Heated at $60-1^\circ$ in a current of dry air it lost 6.66% and became coffee-colored. In the 1st 14 hrs. it lost about 1.5 mol. H_2O and the remaining 0.5 mol. in 14 hrs. more. The dry salt is completely hydrated on standing in the air and is not deliquescent. When $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ is left in a desiccator over H_2SO_4 , the 1st H_2O is eliminated in about 540 hrs., the 2nd in 670 hrs. Another specimen heated at 55° lost 11.6% H_2O in 9 hrs. (1 mol.) and the remainder in 46 hrs. more. Some H_2O was also lost at 41° . The temp. of dehydration over H_2SO_4 at 10 mm. may be 24° and even 15° ; in dry air it may be 55° . *Sodium bromide*, $\text{NaBr} \cdot 2\text{H}_2\text{O}$ lost 12.77% H_2O (1 mol. = 12.95%) in 23 hrs. at 30° ; after 28 hrs. more it had lost 26.6% (calcd. for $2\text{H}_2\text{O}$ = 25.9%). *Sodium iodide*, $\text{NaI} \cdot 2\text{H}_2\text{O}$, lost 11.91% H_2O in 72 hrs. over H_2SO_4 and 20.17% in 113 hrs. more. The data in the literature about *cadmium acetate* are discordant. $\text{Cd}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$ lost about 1 H_2O over H_2SO_4 at $12-14^\circ$ for 32 days and 14.08% H_2O in 56 days more (calcd. 13.4% H_2O). At 30° it lost 0.66% H_2O ; at 50° $2\text{H}_2\text{O}$ were lost without any arrest point. In a desiccator over H_2SO_4 it lost 0.6% in 24 hrs. and at 20 mm. in 200 hrs. it lost $2\text{H}_2\text{O}$. At 99° it lost 11.54% H_2O in 3 hrs. or 13.54 ($2\text{H}_2\text{O}$) in 15 hrs. more. This salt probably

has a multiple formula since it loses 1.75 H₂O so quickly. *Potassium ethylidene disulfate* at 30° for 10 hrs. lost 11.21% H₂O and in 5.5 hrs. more had lost 11.92% (calcd. for 2 H₂O 11.91%); the 1st mol. is eliminated relatively easily. Over CaCl₂ it lost the 1st mol. much more easily than the 2nd. This salt may thus be written (MeCH₂(SO₂K)₂.H₂O).H₂O. According to Pape (*Pogg. Ann.* 125, 513) *sodium dithionate* effloresces at 55°. Kept for 12 days at room temp. over H₂SO₄, it lost 7.8% H₂O (1 mol. H₂O = 7.4%), in 35 days more 14.60% H₂O; *i. e.*, the 2nd mol. is eliminated much more slowly. In a current of dry air at 42° it lost 8.3% H₂O in 5.5 hrs.; and in 13.5 hrs. more 14.47% had been lost; *i. e.*, 1 H₂O is lost in 5 hrs. and the other in 14–15 hrs. more. It did not lose wt. at 30° nor 40° but at 50° in 24 to 30 hrs. it lost 2 H₂O. No point of arrest was observed. This salt may be represented thus: (Na₂S₂O₆.H₂O).H₂O. According to Heeren *barium dithionate*, BaS₂O₆.2H₂O, effloresces rapidly and loses 0.5 of its H₂O. In 3 hrs. at 98–9° it lost 2 H₂O. Over H₂SO₄ at 20 mm. it lost 5.01% H₂O in 4 days and 10.64% (calcd. 10.81%) in 12 days more, *i. e.*, the 1st mol. is eliminated much more rapidly. At 30° and 40° no H₂O was lost, after 17 hrs. at 50° 3.88% was lost, after 9 hrs. more 7.0%, after 16 hrs. more 10.30% and after 24 hrs. more 10.77% H₂O was lost. In the air it reabsorbs 2 H₂O in a few days. Over H₂SO₄ at 30° it lost 2 H₂O in 48 hrs. This salt may be represented thus: (BaS₂O₆.H₂O).H₂O, although there was no true point of arrest. Other expts. on salts containing 2 H₂O will be discussed in another paper. Expts. on salts with 3, 4, 5 and 7 H₂O and alums with 12 or 24 H₂O are complete.

E. J. WITZEMANN.

The constitution of nitrogen tetroxide and the products that it forms with limited amounts of water. GIUSEPPE ODDO. Univ. Pavia. *Gazz. chim. ital.* 45, I, 413–43 (1915).—Several facts, some of which need confirmation, have drawn attention to the O compds. of N. The recent work is reviewed and references are given. Hibbert (*C. A.* 9, 150) found a stable and an unstable nitroglycerin and suggests that the stable

form is the ester of (HO)O:N  N(OH)  N:O(OH). O. suggests that KNO₃·

2HNO₃ may be the monopotassic salt of such a trinitric acid, and KNO₃.HNO₃ the

acid salt of (HO)O:N  N:O(OH). O. has studied N₂O₄ experimentally from some

of the new points of view. *Prepn. and properties of pure N₂O₄*. The N₂O₄ used was prepared in part in the lab. by heating Pb(NO₃)₂ and obtained in part from the factory of Schuchardt of Görlitz. When the product still contains some hydrate it is colored dark green-brown, the vapors are rutile-red, and it boiled from about 22° upward. It must be purified in all-glass app. The dehydration is completed with P₂O₅ and is slow. After long treatment the main fraction boils 22–3°, which agrees well with earlier results of others; higher values arise from incomplete dehydration. This product was further purified by crystg. fractionally 3 times by cooling with ice and HCl or NaCl without inoculating, but it was very convenient to induce crystn. with CO₂ snow, and finish in ice-NaCl bath. The pure N₂O₄ is a limpid, rose-red liquid, f. p. –9.04. Lower f. ps. found by others are attributed to impurities. The pure cryst. product appears as a compact, colorless, hyaline mass on the outside and in the center where it freezes last it often shows fractures that give the appearance of crystals. As the temp. rises in melting the upper part of the gel becomes yellow, suggesting that it is a solid soln. of NO₂ in N₂O₄. It is yellow when melted. It may be preserved unchanged indefinitely in sealed tubes or in glass-stoppered vessels in P₂O₅-desiccators. If it becomes hydrated the rose color is replaced by a greenish hue. *Dets. of the mol. wt. of N₂O₄ in various solvents*. O. repeated some expts. of earlier workers on the mol.

wt. purifying his solvents very carefully. Mol. wt. detns. in AcOH by the f.-p. method showed that in this solvent N_2O_4 has a mol. wt. of 77.1 to 87.5. This result differs a little from that of Ramsay (*J. Chem. Soc.* 53, 621(1888)) and coincides with that of Cundal (*Ber.* 29, 492(1892); 29, 265, 831(1896)); it shows that at the f. p. of AcOH some N_2O_4 is dissociated into NO_2 . The fact that this dissociation increases with the concn. although the f. p. is lowered, shows that the dissociation is accompanied by combination with the solvent. The mol. wt. of N_2O_4 is normal or a little higher for N_2O_4 in $PhNO_2$. O. thinks that the aggregation of N_2O_4 in this case just about balances the dissociation into NO_2 . In small concns. the mol. wt. is normal in C_6H_6 soln. but increases with increase in concn. thus showing a definite tendency to polymerize in C_6H_6 . *Constitution of N_2O_4 and the action of small amts. of H_2O on it.* O. discusses historically 3 formulas commonly assigned to N_2O_4 : (1) $ON.O.NO_2$, (2) $O_2N.NO_2$, (3) $O:N.O.O:N:O$. The most commonly accepted is (1). The formulas of Thomlinson (*C. A.* 3, 2418) and Rotarski (*C. A.* 4, 2763) are given. Much light is thrown on the constitution of N_2O_4 by its action with H_2O in excess; the result may be indicated thus: (1) $N_2O_4 + H_2O \longrightarrow HNO_3 + HNO_2$ or (2) $3N_2O_4 + 2H_2O \longrightarrow 4HNO_3 + 2NO$. O., however, has preferred to start off on a new tack. Without discussing the merits of the arguments of Raschig, Lunge and Berl on the relative stability of N_2O_4 or N_2O_3 , etc., O. points out that N_2O_4 is the most stable oxide, since all but N_2O tend to pass over into it spontaneously. Since the cyclic compds. are most stable in org. chemistry, O. proposes 2 formulas, (I) and (II). Either one is capable of explaining the reactions of

N_2O_4 . For the same reason he proposes (III) for NO_2 and suggests that it be called "hypozoside." This formula makes NO_2 a compd. distinct from N_2O_4 . True N_2O_4 is known as solid, liquid and gas, while NO_2 is known only as a gas. There ought to be a liquid and solid state for NO_2 and its physical constants would be intermediate between those of CO_2 and O_3 . NO_2 will be discussed in a later paper. Assuming that (I) or (II) acts with H_2O one gets $N_2O_4 + H_2O \rightleftharpoons H_2N_2O_4$, i. e., (IV) or (VI) are formed. O. does not consider it necessary to exclude the existence of the possible common intermediate mesohydric form (V), and considers if $H_2N_2O_4$ is really formed that the 3 products are in equil. with each other. (VI) may be a true acid formed by the union of $HNO_2 + HNO_2$ and might be called "nitrousic" acid. It is probably unstable and could

give the internal NH_4 salt (VII); but this like all nonquaternary NH_4 compds. would be unstable and by the loss of H_2O would give $\text{N}_2\text{O}_4 + \text{H}_2\text{O}$. O. made expts. to see if free nitrous acid is formed by the action of H_2O on N_2O_4 . In the cryoscopic expts. he found that N_2O_4 does not react appreciably with H_2O at -9° , the m. p.; only a small amt. is dissolved. The results of the detn. of the mol. wt. of H_2O in this solvent will be described. O. studied the effect of H_2O on N_2O_4 dissolved in the solvents used above. If N_2O_4 is (1), (2) or (3) (cf. above) and if H_2O reacts thus, (1) $\text{N}_2\text{O}_4 + \text{H}_2\text{O} = \text{HNO}_3 + \text{HNO}_2$, the cryoscopically active particles of the soln. would be increased in an amt. corresponding to that of the H_2O added, and its mol. wt. would be about 18. If (2), $3\text{N}_2\text{O}_4 + 2\text{H}_2\text{O} = 4\text{HNO}_3 + 2\text{NO}$, there are about 5 active particles on one side and 6 on the other, of which 2 are eliminable as gas, from which O. calcs. that the mol. wt. of H_2O would appear to be from a minimum of 12 to a maximum of 36. If $\text{N}_2\text{O}_4 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{N}_2\text{O}_3$ there will be no change in the f. p. and the mol. wt. would approach infinity with increasing concns. *Solns. in PhNO_2 .* H_2O is little sol. in PhNO_2 . In order to det. its mol. wt. in PhNO_2 , 16.8298 g. PhNO_2 were placed in the cryoscope and the f. p. detd.; then 1 drop of H_2O (0.0272 g.) was added and the mixt. agitated but soln. was incomplete. After adding 0.8883 g. more PhNO_2 , soln. was complete and the mol. wt. was 22.1; on adding more PhNO_2 , the mol. wt. was 19 and with still more 18.5. The mol. wt. of H_2O is simple in high diln., but increases with the concn. These results were confirmed several times. The f. p. of a mixt. containing excess H_2O was detd. and by Raoult's formula, assuming the apparent mol. wt. of water to be 22, the solubility of H_2O in PhNO_2 was calcd. as 0.1260%. The solns. of N_2O_4 in PhNO_2 used in detg. the mol. wt. of N_2O_4 above were treated with small known amts. of H_2O and gave a f. p. lowering corresponding to a mol. wt. of ≈ 53 for H_2O . This might conform to the reactions $\text{N}_2\text{O}_4 + 3\text{H}_2\text{O} \longrightarrow \text{NO}(\text{OH})_2 + \text{N}(\text{OH})_3$ or $\text{N}_2\text{O}_4 + 3\text{H}_2\text{O} \longrightarrow \text{N}(\text{OH})_4 + \text{NOOH}$, but the instability of such products renders the reaction, $3\text{N}_2\text{O}_4 + 3\text{H}_2\text{O} \longrightarrow 2\text{H}_2\text{N}_2\text{O}_3 + \text{HNO}_3 + \text{HNO}_2$, more probable and since $\text{H}_2\text{N}_2\text{O}_3$ was conceived as an addition product of $\text{HNO}_3 + \text{HNO}_2$ this dissociation would diminish with increasing concn. and would cause the apparent mol. wt. of H_2O to rise with increasing concn. as was observed. *Solns. in C_6H_6 .* O. attempted without success, to det. the mol. wt. of H_2O in C_6H_6 . Approx. 0.0137% H_2O is sol. in C_6H_6 . The solns. of N_2O_4 in C_6H_6 used in detg. the mol. wt. of N_2O_4 above were treated with small known amts. of H_2O . The results show that in C_6H_6 soln. too, $\text{H}_2\text{N}_2\text{O}_3$ is formed, which for the most part remains dissolved, and that when a solid soln. between the 2 solvents and the hydrate is formed the greater concn. of the hydrate occurs in the solid phase. *Solns. in AcOH .* The f. p. curve of H_2O in AcOH was detd. The mol. wt. of H_2O in dil. solns. of AcOH is always greater than 18; it increases with increase in concn., but even at 6.52% H_2O , it is 29, i. e., less than dimolecular. O. shows by a series of data in which the H_2O was added a little at a time that in passing from 5.15% H_2O to 6.5% H_2O the f. p. lowering corresponds to a mol. wt. of 39 for this portion of the H_2O present. By detg. the mol. wt. of H_2O in the N_2O_4 solns. in AcOH used above, the same values that are obtained in the absence of N_2O_4 were obtained, thus showing that the N_2O_4 present does not have any effect. In order to confirm the preceding, the behavior of N_2O_4 in solns. of H_2O in AcOH was studied. The results show that the only effect of N_2O_4 obtained may in this case also be ascribed to diln. But O. questions whether the N_2O_4 may not combine with the H_2O . *Action of EtOH on solns. of N_2O_4 .* The mol. wt. of EtOH in C_6H_6 varies from 54 to 89. Using a 3.722% N_2O_4 soln. in PhNO_2 and adding EtOH mol. wts. for the latter, from 46.3 to 98.0 were obtained. At strong diln. the mol. wt. is normal, and at 3% it is 98, thus showing that N_2O_4 is without effect on EtOH in PhNO_2 . The mol. wt. of EtOH in C_6H_6 varies from 63 to 80.1. Solns. containing 0.763% N_2O_4 showed mol. wts. of 74.3 to 102.7 for EtOH , which shows that part of

the N_2O_4 combines with EtOH and may give the monoethyl "nitrousate," $O:N-$

Summary. N_2O_4 in $PhNO_2$ shows nearly all simple mols., but in C_6H_6 it shows a definite tendency to polymerize and in AcOH it dissociates into $2NO_2$. H_2O shows simple mols. in small concns. in $PhNO_2$ but in solns. of N_2O_4 in $PhNO_2$ it shows triple values which shows that the hydrate of N_2O_4 (IV) or (VI) is formed. This acid arises from the addition of 1 mol. of HNO_2 to 1 mol. of HNO_3 . The basic character of the $:NOH$ group tends to cause a rearrangement that was discussed above. The formation of (IV) or (VI) was supported by the behavior of H_2O in solns. of N_2O_4 in C_6H_6 , and possibly in solns. of N_2O_4 in AcOH, as well as with solns. of EtOH in solns. of N_2O_4 in C_6H_6 . Thus the org. compds. derived from N_2O_4 and the complex nitrates

mentioned above are derivs. of binitric acid, $HO(O:)N \begin{array}{c} \diagup \quad \diagdown \\ \diagdown \quad \diagup \end{array} N(:O)OH$ and trinitric

E. J. WITZEMANN.

Chlorous acid and chlorites. G. BRUNI AND G. LEVI. *Atti ist. Veneto sci. let. arti* 74, II, 1711-32.—The following investigation of the properties of chlorites and chlorous acid is preceded by a comprehensive review of the literature of the subject. The authors prepare $KClO_2$ by the following modification of the usual method: a mixt. of 150 parts oxalic acid, 40 pts. $KClO_3$ and 20 pts. H_2O is heated to 60° , the soln. concd. to crystn. *in vacuo* at 50° , cooled and then treated with 3 vols. of abs. EtOH from which the chlorite is obtained by fractional crystn. The residue gives a further yield of chlorite on treatment with 95% EtOH. By treating $AgClO_2$ (prepared from $KClO_3$ and $AgNO_3$) with concd. NH_4OH , the authors obtained $AgClO_2 \cdot NH_3$ as yellow crystals. $AgClO_2$ dissolved in ammoniacal EtOH and pptd. with anhydrous Et_2O , yields white crystals of $AgClO_2 \cdot (NH_3)_2$. This salt is unstable in air, losing NH_3 and becoming yellow. Dry gaseous NH_3 slowly passed over $AgClO_2$ yields a white cryst. mass of $AgClO_2 \cdot (NH_3)_2$, unstable at ordinary temp., rapidly losing NH_3 and becoming yellow. $Ba(ClO_2)_2$ was prepared by passing a stream of ClO_2 (Cl_2 -free) and CO_2 into a suspension of BaO in H_2O , extg. with EtOH, adding an excess of Et_2O to the ext. and rapidly drying the ppt. thus obtained in order to free it from traces of EtOH and Et_2O . With rapid filtration and drying, the ppt. of $Ba(ClO_2)_2$ is very pure and free from chloride. In similar manner, the authors obtained $Ca(ClO_2)_2$, $Sr(ClO_2)_2$ and $LiClO_2$. $NaClO_2$ was obtained by adding Na_2SO_4 to $Ba(ClO_2)_2$ and evapp. the soln. *in vacuo*. Hydroxylamine chlorite was prepared by the action of hydroxylamine sulfate on $Ba(ClO_2)_2$. The salt is unstable at ordinary temp. $Hg(ClO_2)_2$, prepared as a red cryst. ppt. by treating $Hg(NO_3)_2$ with $Ba(ClO_2)_2$ or $KClO_3$, is extremely unstable when dry, exploding spontaneously. $HgClO_2$ prepd. similarly from $HgNO_3$ as a cryst. yellow ppt. exhibits properties similar to the mercuric salt. The mol. conds. of the salts $KClO_2$, $AgClO_2$ and $Ba(ClO_2)_2$ were detd. at 25° and the mobility of the ClO_2^- ion found to be 51.0. Detns. of the mobilities of the ClO_2^- , ClO_4^- , NO_2^- and NO_3^- ions at 25° compared with this are ClO_2^- 51.0, ClO_4^- 63.4, ClO_4^- 73.6, NO_2^- 75.4, NO_3^- 70.6. In the case of the oxygen compds. of Cl, the ion mobility apparently increases with increase in O content, while in those of N it decreases. The degree of dissociation of $KClO_2$ detd. by cryoscopic measurements over a range of 4 dilns. was found to average $\alpha = 0.938$. The chlorites do not manifest apparent hydrolysis. Measurements of the heat of decompn. of $Ba(ClO_2)_2$ give, as a mean value, $Ba(ClO_2)_2 = BaCl_2 + 2O_2 + 48.6 \text{ Cal.}$

Alumina and aluminates. ERNEST MARTIN. *Mon. sci.* [5] 5, 225-32(1915).

—The marked differences in the properties of the hydrate of Al resulting from the auto-decompn. of alkaline aluminates according to Bayer's reaction and those of the hydrate obtained in pptg. the soln. of an Al salt with NH_4OH , suggest a difference in structure. The first, dried in air, maintains a const. compn. corresponding to $\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ and is not hygroscopic. On being heated it begins to lose H_2O at 160° , at 225° has lost one molecule, and at 235° , a second. The last traces, however, are not expelled

below 1000° . Its formula is probably $\text{Al} \begin{array}{l} \diagup \text{OH} \\ \diagdown \text{OH} \\ \diagup \text{OH} \end{array}$. The 2nd hydrate is gelatinous and

its compn. varies according to the conditions of pptn. Dried at 80° its compn. approximates $\text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$, but at higher temps. its loss of H_2O is continuous and at no point does it behave like a well defined hydrate. M. does not assign it a structural formula. In a study of the aluminates of the alkaline earths he obtained the series, $n \text{Al}_2\text{O}_3 \cdot (n + 1)\text{MO}$. Also aluminates richer in the base were formed. $\text{Al}_2\text{O}_3 \cdot 3\text{BaO}$ was formed with the use of the elec. arc at temps. above 1500° only, all mixts. below that point giving the mono-Ba compd. Mixts. of 1 Al_2O_3 to 1, 2, and 3 CaCO_3 gave at about 1500° , $\text{Al}_2\text{O}_3 \cdot \text{CaO}$, $\text{Al}_2\text{O}_3 \cdot 2\text{CaO}$ and $\text{Al}_2\text{O}_3 \cdot 3\text{CaO}$. Higher temps. produced compds. of $2\text{Al}_2\text{O}_3 \cdot 3\text{CaO}$, $5\text{Al}_2\text{O}_3 \cdot 6\text{CaO}$ and $10\text{Al}_2\text{O}_3 \cdot 11\text{CaO}$. Mixts. of Al_2O_3 , BaSO_4 and C in mol. proportions gave on being heated, thioaluminates of the compn. $\text{Al}_2\text{O}_3 \cdot 2\text{BaS}$ and $2\text{Al}_2\text{O}_3 \cdot 3\text{BaS}$ which are sol. in H_2O but which hydrolyze rapidly with evolution of H_2S . Analogous Ca compds. were obtained with the use of CaSO_4 .

Thermal analysis of the alkali polyarsenates. M. AMADORI. *Atti ist. Veneto sci. let. arti* 73, II, 1665-78(1913-4).—A. has investigated the alkali polyarsenates with a view to finding compds. similar in structure to the sodium salts of the acids $\text{H}_2\text{P}_3\text{O}_{10}$, $\text{H}_2\text{P}_4\text{O}_{13}$ and $\text{H}_2\text{P}_5\text{O}_{16}$. For this purpose the salt was fused in a porcelain crucible in a resistance furnace, the temp. being followed by means of a thermoelement and galvanometer. The results of an extended series of expts. show that besides the orthoarsenates, there exist alkali metaarsenates and pyroarsenates. The temp. of solidification (*s*) and transformation (*t*) of the Na and K salts are, resp.: NaAsO_3 *s* = 615° , *t* = —; $\text{Na}_2\text{As}_2\text{O}_7$ *s* = 850° , *t* = 688° ; $\text{Na}_3\text{As}_3\text{O}_{10}$ *s* = 1260° , *t* = 410° ; KAsO_3 *s* = 650° , *t* = 450° ; $\text{K}_2\text{As}_2\text{O}_7$ *s* = 996° , *t* = 400° ; $\text{K}_3\text{As}_3\text{O}_{10}$ *s* = 1310° , *t* = 400° . Besides these derivs., thermal analysis demonstrates the formation of a compound of the type $\text{M}_4\text{As}_4\text{O}_{16}$. This is formed, on solidification by the reaction between the metaarsenate MAsO_3 and the pyroarsenate $\text{M}_2\text{As}_2\text{O}_7$. $\text{Na}_4\text{As}_4\text{O}_{16}$ is formed at 697° and $\text{K}_4\text{As}_4\text{O}_{16}$ at 630° . The formation of salts of this type also occurs at high temps., as in the case of the corresponding phosphates. As in the case of the phosphates, there is no indication of the formation of a compd. of the type $\text{M}_6\text{R}_6\text{O}_{18}$.

L. T. FAIRHALL.

Triamminoquo salts of bivalent platinum. I. CHUGAEV AND I. CHERNIAEV. *Compt. rend.* 161, 792-4(1915); cf. *C. A.* 10, 432.—A current of air passed into a

soln. of the chloride $\left[\begin{array}{ccc} \text{NH}_3 & & \text{NH}_2\text{OH} \\ & \diagdown \quad \diagup & \\ & \text{PT} & \\ & \diagup \quad \diagdown & \\ \text{HONH}_2 & & \text{NH}_3 \end{array} \right] \text{Cl}_2$ with the addition of NH_3 ,

$(\text{NH}_4)_2\text{SO}_4$ or other sol. sulfate, and a small quantity of a Cu salt, oxidizes the hydroxylamine compd., producing a cryst. ppt. sol. in warm dil. H_2SO_4 . This acid soln., filtered and cooled, gives on the addition of a soln. of K_2PtCl_4 a green cryst. ppt. of $[\text{Pt}(\text{NH}_3)_3(\text{H}_2\text{O})]\text{PtCl}_4$, the aquo base of which is $[\text{Pt}(\text{NH}_3)_3(\text{H}_2\text{O})](\text{OH})_2$. The bromo deriv. may be similarly prepared from the bromide. When the *trans*-chloride $[\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{OH})_2]\text{Cl}_2$ is similarly oxidized, an homogeneous cryst. ppt. is obtained, which is per-

factly sol. in dil. H_2SO_4 and behaves in its reactions similarly to the preceding salts.

The hypothetical formula deduced for this is $\left[(\text{NH}_3)_4\text{Pt} \begin{array}{c} \diagup \text{OH} \\ \diagdown \text{OH} \end{array} \text{Pt}(\text{NH}_3)_4 \right] \text{SO}_4$.

L. T. FAIRHALL.

The tellurides of silver and of gold. GIOVANNI PELLINI. Univ. Cagliari. *Gazz. chim. ital.* 45, I, 469-84(1915); cf. P. and Quercigh (*C. A.* 5, 1884, 2042).—The binary systems Te-Au and Te-Ag were previously studied and P. now reports on the ternary system Ag-Au-Te or more accurately the system $\text{Ag}_3\text{Te-AuTe}_2\text{-Te}$ since this has greater interest because of the large number of double tellurides of Ag and Au existing in nature. Besides hessite (Ag_3Te) and silvinit ((Ag, Au)Te₂) the minerals calaverite and krennerite, which have a variable compn. of the AuTe_2 type, a small part of the Au being replaced by Ag, are known. When Ag preponderates, the mineral is muthmannite (Ag, Au)Te (Zambonini, *C. A.* 5, 3783) in which the $\text{M}^{\text{I}}\text{Te}$ type of compd. found by P. and Q. (*l. c.*) occurs. Empressite (M. W. Bradley, *C. A.* 8, 3169) is nearly pure AgTe . Goldschmidtite is (Au, Ag)₂Te₃ (Gastaldi, *C. A.* 6, 1420). Petzite is thought to be hessite (Ag_3Te) in which Ag is replaced in part by Au. Speculite is similar to silvanite but differs in compn. The number of these minerals renders the study of the system Ag-Au-Te of interest especially since the attempts of Lehner (*J. Am. Chem. Soc.* 24, 335(1902)) and Tibbals (*C. A.* 3, 2420) to obtain Au tellurides in the wet way failed. Au salts react differently from the Ag salts: (1) $4\text{AuCl}_3 + 3\text{Te} \rightarrow 4\text{Au} + 3\text{TeCl}_4$; (2) $2\text{AuCl}_3 + \text{H}_2\text{Te} \rightarrow 2\text{Au} + \text{TeCl}_4 + 2\text{HCl}$; (3) $2\text{AuCl}_3 + \text{Na}_2\text{Te} \rightarrow 2\text{NaCl} + \text{TeCl}_4 + 2\text{Au}$; and Au is pptd. instead of a telluride. L. concluded that the more common deposition of double tellurides of Au and Ag depends on the reaction of AuCl_3 and AgCl in solns. of alkali chlorides with solns. of alkali sulfides containing Te. The same method was used in studying this system as was used before; 20 g. of each mixt. were used; oxidation was prevented by a current of N; the temps. were detd. with a Pt + PtRh couple. *The 3 binary systems: Ag-Te, Au-Te, and Ag₃Te-AuTe₂.* The results on the 1st 2 systems have been published. The partial systems $\text{Ag}_3\text{Te-Te}$ and $\text{AuTe}_2\text{-Te}$ are of interest for this problem. Ag_3Te melts without decompn. at 961°. With increasing Te content AgTe is formed by reacting with Ag_3Te primarily deposited. The fused mass in which AgTe is formed has a concn. of 47 atom % Ag; the temp. of formation is about 444°. At 412° AgTe undergoes the transformation: $\beta\text{-AgTe} \rightarrow \alpha\text{-AgTe}$ and the concn. of Ag in the fused mass is now 44 atom %. $\alpha\text{-AgTe}$ gives a eutectic with Te at 351° and a concn. of 33.3 atom % Ag. Pure Te m. 451°. In the partial system AuTe-Te there is only 1 eutectic point at 416° and 16 atom % Au. The telluride m. 464°, without decompn. Results for the system $\text{Ag}_3\text{Te-AuTe}_2$ are tabulated. Starting from the f. p. of AuTe_2 (464°) the primary crystn. curve drops gradually to a eutectic at 373° (at 35 atom % Ag for 100 of the ternary mixt.). From this point the curve rises rapidly to the m. p. of Ag_3Te (961°). All alloys having more than 46.5 atom % of Ag show an arrest at 495° where the compd. Ag_3Te reacts with the fused mass to give a new compd. It is not easy to det. the compn. of the new compd. (1) since at the temp. of formation no sharp arrest is observed, only superfusion taking place, and the point of max. arrest which fixes the compn. cannot be detd.; (2) the reaction between the fused mass and Ag_3Te is incomplete, which is shown by prolongation of the eutectic arrest (373°) nearly up to the concn. of the compd. Ag_3Te . For concns. higher than 55 atom % Ag, the duration of arrest was short. For a concn. of 55 atom %, Ag 5.7 atoms Au and 39.3 atoms Te are required, which corresponds to the compd. $\text{Ag}_{11}\text{Au}_2\text{Te}_{11}$, and agrees closely with the simpler formula (Ag, Au)₃Te₂ (Ag = 53.34 atom %). Such a formula is rendered plausible by the fact that umangite (cf. Klockmann, *Z. Kryst. Min.* 19, 269(1891)) is Cu_3Se_2 and

by the fact that $\text{Na} + \text{Te}$ give Na_2Te_3 (P. and Quercigh, *C. A.* 5, 1567). The numerous analyses of petzite show that the compn. of the mineral is variable not only in the Ag and Au content but also in the ratio of $\text{Au} + \text{Ag}$ to Te. Moreover Au and Ag tellurides have been found to which the formulas $(\text{Ag}, \text{Au})_3\text{Te}_2$ and $(\text{Ag}, \text{Au})_4\text{Te}_3$ may be assigned but which have been regarded as mixts. It is thus probable that by a further study of these minerals they will show their relations to the ternary compd. $(\text{Ag}, \text{Au})_3\text{Te}_2$ found in the system $\text{Ag}_2\text{Te}-\text{AuTe}_2$. The reaction taking place at 495° may be expressed thus: $(\text{Ag}, \text{Au})_3\text{Te}_2 \rightleftharpoons \text{Ag}_2\text{Te} + \text{fused mass}$. The ternary system $\text{Ag}_2\text{Te}-\text{AuTe}_2-\text{Te}$.

A large number of detns. was made on this system since the phenomena that occur during crystn. present many difficulties. The numerical data are given for 113 alloys. The results are represented diagrammatically in Figs. 1 and 2. As is shown in Fig. 2 the compds. AgTe and $(\text{Ag}, \text{Au})_3\text{Te}_2$ melt with decompn. both in the binary system and the ternary system since the compd. AgTe does not crystallize primarily on the transversal $\text{AgTe}-\text{AuTe}_2$ and also since $(\text{Ag}, \text{Au})_3\text{Te}_2$ does not crystallize primarily on the

transversal $(\text{Ag}, \text{Au})_3\text{Te}_2$. This ternary system shows 4 points of invariant equil. a , b , c and e . The point a at about 412° shows an atomic concn. of 52 Te, 44.7 Ag, 3.3 Au and is the point of invariant equil. of 3 solids and 1 liquid, thus: $\beta\text{-AgTe} + \alpha\text{-AgTe} \rightleftharpoons \text{Ag}_2\text{Te} + \text{fused mass } a$. b lies at 385° with 53 Te, 42.7 Ag, 4.3 Au and represents the point of invariant equil. for $\alpha\text{-AgTe} + (\text{Ag}, \text{Au})_3\text{Te}_2 \rightleftharpoons \text{Ag}_2\text{Te} + \text{fused mass } b$. c lies at 340° with 57 Te, 37 Ag, 6Au and the equil. is: $\alpha\text{-AgTe} + \text{AuTe}_2 \rightleftharpoons (\text{Ag}, \text{Au})_3\text{Te}_2 + \text{fused mass } c$. e lies at 335° with 60 Te, 35 Ag, 5Au and is the equil. pt. for the 3 solids $\alpha\text{-AgTe}$, AuTe_2 , Te and the fused mass e . Below 335° all alloys are solid. In this system there are 9 curves of invariant equil. (1) Gb drops from 495 to 385° ; (2) Fa drops from 444 to 412° ; (3) ab from 412 to 385° ; (4) bc from 373 to 340° ; (5) ce from 340 to 335° ; (6) e_2c from 373 to 340° ; (7) e_1e from 416 to 335° ; (8) c_2e from 351 to 335° ; (9) Ha shows no drop in temp. The solids in equil. along the lines named are indicated by the fig. The triangle is divided into 6 zones for the 6 solids and the compd. that 1st seps. from alloys in each zone is indicated in the fig. The zone of primary crystn. of the compd. Ag_2Te presents a difficulty in the interpretation of results. The location of the curve Gb is only suggested. In fact all alloys that in the course of their crystn. cross the line Gb show a lowering of the temp. corresponding to the point of intersection where theoretically the compd. $(\text{Ag}, \text{Au})_3\text{Te}_2$ should be formed by the reaction of Ag_2Te and the fused mass. Instead superfusion occurs to about 495° which is the temp. of formation of the compd. in the binary system $\text{Ag}_2\text{Te}-\text{AuTe}_2$. All alloys that cross Fa , ab or Gb in crystn. show an arrest at b 385° . Thus the superfusion at 495° depends on the irregular reaction of formation of $(\text{Ag}, \text{Au})_3\text{Te}_2$ for otherwise the alloy with a large Au content ought to lack the arrest at b at 385° and show instead a lowering in the crystn. curve corre-

sponding to ϵ_{sc} , which was not found. The curve $H\alpha$ is also only suggested.

E. J. WITZEMANN.

The systems barium oxide, acetic acid, water and magnesium oxide, acetic acid, water. J. IWAKI. *Mem. Coll. Sci. Kyoto Imp. Univ.* 1, 81-8 (1914); *J. Soc. Chem. Ind.* 34, 609.—A study of the equil. of the systems at 25° established the existence of the following acid salts: $3(\text{AcO})_2\text{Ba} \cdot 3\text{AcOH} \cdot 11\text{H}_2\text{O}$, $(\text{AcO})_2\text{Ba} \cdot 2\text{AcOH}$, $2(\text{AcO}) \cdot \text{Mg} \cdot 3\text{AcOH} \cdot 3\text{H}_2\text{O}$ and $5(\text{AcO})_2\text{Mg} \cdot 10\text{AcOH} \cdot 7\text{H}_2\text{O}$.

E. J. C.

The alloy of manganese and bismuth. N. PARRAVANO AND U. PERRI. *Univ. Padoa. Gazz. chim. ital.* 45, 390-4 (1915).—Wedekind and Weit (*C. A.* 6, 42) obtained a compd. MnBi and Hilpert and Dieckmann (*C. A.* 6, 460) by another method found the same compd. Bekier (*C. A.* 9, 779) studied the diagram of state of the alloy Mn-Bi and obtained results differing from those of P. and P. The facts that the 2 metals are partially miscible in the liquid state and form a compd. that arises through a "peritectic" reaction at about 450° were confirmed. But the results on the concn. of the 2 liquid layers in equil. at high temp., and on the compn. of the compd. differed. P. and P. analyzed the 2 layers of the alloys used in detg. the f. p. curve. They were cooled slowly and found to contain from 26.7 to 28.8% Mn in the layer poor in Mn and 81.4 to 88.8% Mn in the Mn-rich layer. In order to det. the effect of the rate of cooling, several alloys were quickly cooled with H_2O and showed 28.66 to 29.40% Mn in the one and 89.6 to 92.8% Mn in the other layer. It is thus impossible to attribute the difference observed in the Mn content of the 2 layers to a defect in the sepn. of the 2 liquids. H. and D. found that the Si in the Mn-rich layer increased from 1.53% in the original to 7.55%. P. and P. used magnesia crucibles and found an increase from 0.99% in the original to 1.25 to 1.45% in the alloy. In the diagram the invariant temp. of equil. between the 2 liquids was fixed at 1238° and the 2 liquids contain 30 and 93% Mn, resp. B. could not assign a definite formula to the compd. between Mn and Bi. P. and P. prepd. mixts. corresponding to BiMn , Bi_2Mn , and BiMn_2 and found that although the reaction of formation is always incomplete the cooling curve indicates with some security the formulas of compds. The max. thermal effect occurs at 450° and a thermal arrest of about 100 min. occurs with an alloy of 20% Mn while with alloys containing more or less Mn, the thermal arrest did not seem so great. This speaks in favor of the compd. MnBi (20.90% Mn). The presence of 2 liquid layers does not weaken this result.

E. J. WITZEMANN.

Complex salts of iron. IV. G. SPACU. *Ann. sci. univ. Jassy* 9, 117-38 (1915); *Chem. Zentr.* 1915, II, 349-50; cf. *C. A.* 9, 180; 8, 3158.—By heating 5 g. of very finely pulverized $\text{FeSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ for $\frac{1}{2}$ hr. with 30 g. of pyridine using a reflux condenser the compound $[\text{FePy}_6][\text{SO}_4\text{NH}_4]_2$ is formed as a canary yellow cryst. powder, which loses pyridine on exposure to air. It is insol. in pyridine and CHCl_3 , sol. in AcOH , dil. HCl and H_2SO_4 , sol. in oxalic acid, from which soln. the compd. later seps. In H_2O it decomposes with the formation of $\text{Fe}(\text{OH})_3$. The compound $[\text{Fe}(\text{Py}_2)(\text{H}_2\text{O})][\text{NaSO}_4]_2$ is prepared by heating 5 g. of very finely pulverized $\text{FeSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ with 30 g. of pyridine for 45 min., using a reflux condenser. It forms as a canary yellow cryst. powder similar to the foregoing compd. The compound $[\text{FePy}_6][\text{SO}_4]_2 \cdot [\text{NH}_4]_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ is prepared by the action of 50 g. of pyridine on 10 g. of ferric alum at room temp. for 7-8 days and subsequent drying of the product over P_2O_5 . A brick-red powder is formed which is insol. in EtOH , Et_2O , CHCl_3 , acetone and toluene, partly sol. in MeOH (with decompn.), sol. in oxalic acid, HCl and H_2SO_4 . It is decomposed by H_2O with the formation of $\text{Fe}(\text{OH})_3$. The compound $[\text{Fe}(\text{NH}_4)_4][\text{NH}_4\text{SO}_4]_2$ is prepared by passing dry, air-free NH_3 gas over very finely pulverized $[\text{FePy}_6][\text{NH}_4\text{SO}_4]_2$ for 5 hrs. This is a light yellow powder unstable in air and insol. in the usual solvents. It decomposes in H_2O with the formation of $\text{Fe}(\text{OH})_3$. The compound

$[\text{Fe}(\text{NH}_4)_2(\text{H}_2\text{O})][\text{NH}_4\text{SO}_4]_2$ is prepared as a white cryst. powder by passing dry, air-free NH_3 over finely pulverized $\text{FeSO}_4 \cdot \text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ for 3 hrs. It rapidly colors brown on exposure to air with the simultaneous loss of NH_3 and is insol. in most solvents with the exception of dil. HCl and H_2SO_4 . It decomposes in contact with H_2O forming $\text{Fe}(\text{OH})_2$. The compound $[(\text{FeCl}_2)_2\text{H}_5(\text{C}_6\text{H}_5.\text{NH}.\text{NH}_2)_2]\text{H}_2\text{O}$ is prepared by the action of 5 g. of phenylhydrazine added in small portions to 15 g. $\text{FeCl}_2 \cdot 6\text{H}_2\text{O}$ in 40 cc. of Et_2O . It crystallizes as colorless needles or plates, unstable on exposure to air, sol. in H_2O and EtOH , insol. in Et_2O and CHCl_3 . It is sol. with subsequent decompn. in acetone and gives off HCl on treatment with concd. H_2SO_4 . It dissolves in hot, concd. H_2SO_4 with the formation of a dark blue color and is decomposed by H_2O_2 and Caro's acid. In aq. soln. it gives the reactions of Fe^{++} and Cl^- . The compound $[\text{Co}(\text{Py})_2(\text{H}_2\text{O})_2](\text{KSO}_4)_2$ is formed as a violet cryst. powder by treating 5 g. of finely pulverized $\text{CoSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ with 50 g. of pyridine using a reflux condenser. The product becomes red on standing exposed to air or in an atm. of moist pyridine and is stable only over P_2O_5 . It is sol. in H_2O , insol. in EtOH , Et_2O , CHCl_3 , acetone, toluene and pyridine, sol. in AcOH , dil. HCl and H_2SO_4 , and also in oxalic acid from which the crystals later separate. By the action of air or moist pyridine vapor for 12 hrs. on the foregoing compd., the compound $[\text{Co}(\text{Py})_2(\text{H}_2\text{O})_2](\text{KSO}_4)_2$ is formed as a red colored cryst. powder which is stable on exposure to air and similar in its solubilities to $[\text{Co}(\text{Py})_2(\text{H}_2\text{O})_2](\text{KSO}_4)_2$. It is transformed into the latter by boiling. When $\text{NiSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ (5 g.) is heated for 1.5 hrs. with 60 g. of pyridine in a refluxing app., the compound $[\text{Ni}(\text{Py})_2(\text{H}_2\text{O})_2](\text{NH}_4\text{SO}_4)_2$ is formed as a greenish blue powder, somewhat stable in air, sol. in H_2O , insol. in Et_2O , CHCl_3 , pyridine, acetone, toluene, boiling EtOH , MeOH and amyl alc. It is sol. in AcOH , tartaric and oxalic acids, dil. HCl and H_2SO_4 . The compound $[\text{Cu}(\text{Py})_2(\text{Cl})_2]\text{K}$ is prepd. by treating 5 g. of $\text{CuCl}_2 \cdot 2\text{KCl} \cdot 2\text{H}_2\text{O}$ with 30 g. of pyridine at room temp. for 12 hrs. A greenish blue powder is formed which is stable on exposure to air, sol. in cold H_2O , hydrolyzed by hot H_2O , sol. in hot EtOH from which the compd. crystallizes in blue-green needles, insol. in Et_2O , toluene and xylene, sol. in AcOH and tartaric acid, dil. HCl and H_2SO_4 , sol. in oxalic acid from which soln. the compd. later crystallizes. In aq. soln. the above double salts with pyridine never form amines of similar structure. L. T. FAIRHALL.

Chromium hypophosphite. FR. MAWROW AND J. ZONEW. *Sophia. Z. anorg. allgem. Chem.* 93, 311-2 (1915).— $\text{Cr}(\text{H}_2\text{PO}_2)_2 \cdot 2\text{H}_2\text{O}$ was prepd. as a dark green mass by satg. a soln. of H_2PO_2 with $\text{Cr}(\text{OH})_3$, filtering and evapg. over H_2SO_4 . G. W. M.

The ammonium salts of boric acid. B. L. VANZETTI. *Atti ist. Veneto sci. let. arti* 74, II, 465-71.—V. has investigated the equilibria established between solns. of H_3BO_3 and NH_3 . There is some question as to the compn. of ammonium borate in soln. Lundén's investigations indicate that the compd. $\text{NH}_4\text{H}_2\text{BO}_3$ exists in soln. partially ionized into NH_4^+ and H_2BO_3^- ions. V. prepd. the ammonium salt by treating a soln. of NH_3 (218 g. NH_3 per l. soln.) with an equiv. quantity of pure H_3BO_3 . A white cryst. mass sep'd. (fraction I) and further yields of crystals were obtained from the mother liquor. Analyses showed that NH_3 varied from 7.02% in fraction I to 6.20% in fraction V, while B_2O_3 varied from 60.10% in fraction I to 66.05% in fraction V. The analytical data show a continual diminution in % NH_3 and a corresponding increase in % B_2O_3 due to the volatility of the base formed by hydrolysis. If evapn. is continued for some time, there seps. a cryst. conglomerate which has a compn. approaching that of the pentaborate octahydrate and is stable through all processes of concn. The various solid fractions obtained show somewhat confused cryst. habits. Sodium borate dissolves readily in cold H_2O in the presence of NH_4Cl and deposits crystals corresponding to the compd. $(\text{NH}_4)_{2.0.5}\text{B}_2\text{O}_3 \cdot 8\text{H}_2\text{O}$.

L. T. FAIRHALL.

An explosive mixture of phosphorus and liquid air. A. PIUTTI. *Rend. accad. Lincei* 24, 252-3(1915); through *Ann. chim. applicata* 4, 290.—P. observed that yellow P, immersed in liquid air, did not combine with O at that low temp., but acquired the property of exploding with violence when taken out of the liquid and struck or even touched with a piece of warm Fe, or subjected to the action of an elec. spark. Red P, under the same conditions, does not explode, but burns with a bright flame. Ordinary S behaves similarly. S. LEVY.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Deceptive color changes of indicators. F. LIEBERT. *Chem. Weekblad* 12, 1088-91 (1915).—L. calls attention to the fact that some indicators in the presence of strong alkali and strong H_2SO_4 show a color other than that expected. Phenolphthalein, *e. g.*, in presence of 1:1 KOH is colorless; partial neutralization with acid causes the normal color to return, which proves that the phenolphthalein was not decompd. Rosolic acid and $PhNMe_2$ act in a similar way. Methyl orange, notwithstanding its close relation to $PhNMe_2$, retains its normal color with strong alkali, even when heated. Not only concd. alkali, but also concd. H_2SO_4 is able to produce an abnormal color with phenolphthalein, $PhNMe_2$ and methyl orange. Diln. of the strong H_2SO_4 soln. of these indicators changes the apparent alkaline colors to their normal acid colors. It was furthermore shown that a large number of organic dyes behave in a similar way and L. tabulates the acid, alkaline and strong H_2SO_4 colors of 16 quinone-imide, di- and triphenylmethane and azo dyes. In nearly every case, it was found that the color of the strong H_2SO_4 soln. of these dyes is different from the normal acid color. Only in a few cases, however, the alkaline color was the same as the color of the strong H_2SO_4 soln. of the dye. F. therefore concludes that the apparent alkaline reaction of some indicators with concd. H_2SO_4 is merely accidental and adds that shades of the color in similar cases may differ considerably, as may be seen in the case of phenolphthalein, the alkaline color being red and the strong H_2SO_4 soln. pink. J. T. FLOHL.

Micro balances and their application in chemical analysis. F. EMICH. *Graz. Naturwissenschaften* 3, 693-8(1915); cf. *C. A.* 10, 319.—E. describes the underlying principles and advantages of these balances and then proceeds to discuss the various types in historical order, starting with the Nernst balance (1902). Numerous literature references are appended. C. G. F.

A method for the titration of calcium oxide or hydroxide in the presence of some aluminates or silicates. WARREN E. EMLEY. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 720-6(1915).—By the method here given CaO or $Ca(OH)_2$ can be detd. without difficulty in the presence of $CaOSiO_3$, $2CaOSiO_3$, $CaOAl_2O_3$, $5CaO_3Al_2O_3$, $CaCO_3$ or $CaSO_4$. If $3CaOSiO_3$ is present the method is still applicable but the end point is a little harder to recognize; to a less extent the same is true if MgO is present. With $3CaOAl_2O_3$ special precautions must be taken to insure the absence of H_2O . The alc. should be redistd. from quick-lime immediately before using. The method follows: "In a 250 cc. flask, put 2 cc. of glycerol and 10 cc. of alc. Add the finely powdered sample in sufficient quantity to give about 0.1 g. of free CaO. Add 5 drops of phenolphthalein soln. Bring to a boil, and keep near the boiling point throughout the titration. Titrate with 0.2 N alc. soln. of $NH_4C_2H_3O_2$. The end point is reached when the pink color is discharged and does not return after boiling for 1 min." Many check analyses were run with good results. C. H. KERR.

Electroanalysis of copper without platinum electrodes. J. GUZMAN CARRANCIO AND J. SANZ ULZURRUM. *Anales soc. espñ. fis. quim.* 13, 289-93(1915).—A steel

wire 2 mm. in diam., carefully cleaned with emery and immersed in HNO_3 (1.4 sp. gr.) for 1 or 2 min. was used as an anode in the electrolytic detn. of Cu in CuSO_4 ; a Cu cathode was employed. The electrolyte contained 0.2–0.3 g. Cu and to this were added 5 g. $(\text{NH}_4)_2\text{SO}_4$ and 5 cc. concd. NH_4OH ; successive const. potential differences of 3, 2.5 and 2 volts were maintained during the course of the electrolysis. The same mean % of Cu was obtained under the above conditions as was found when Pt electrodes were employed and HNO_3 was added to the electrolyte. When ammeter, voltmeter and adjustable resistance were eliminated from the circuit (the terminals of the battery being attached directly to the electrodes) and 1 instead of 5 storage cells was used the time required for deposition of Cu was 1 hr. instead of 15 mins. (under the 1st conditions); the other conditions, including stirring, were the same as at first. The amt. of Cu recovered was slightly decreased under these conditions. When stirring was dispensed with (the other conditions being those described immediately above) the amt. of Cu recovered was further decreased to a slight extent and the time required for the deposition of 0.2 g. Cu was increased to 2.5–3 hrs. In order to prevent deposition of Zn, when this metal is present as an impurity in CuSO_4 , it is necessary that the difference of potential shall not exceed 2 volts. Fe and Mg, when present as impurities in small amts., do not interfere with the electrolytic detn. of Cu in CuSO_4 . Mg may be present in considerable amt. without causing inconvenience; Fe in corresponding amt. would, however, be pptd. in the prepn. of the electrolyte. Data showing the results of the analysis of com. CuSO_4 by the 2nd and 3rd procedures described above are given.

H. S. PAINE.

A new method of determining nickel volumetrically. GINO ZUCCARI. Univ. Padoa. *Atti reale ist. Veneto sci. lettere ed arti* 74, 579–82(1915); see C. A. 9, 2200.

E. J. WITZEMANN.

The qualitative separation of silver from univalent mercury. N. VON ZWEIF-BERGK. Upsala. *Z. anorg. allgem. Chem.* 93, 320–6(1915).—The ordinary method in qual. analysis for the sepn. of Ag and Hg, i. e., dissolving the AgCl from the mixed chlorides with NH_4OH , and repptg. by acidifying, is not applicable to mixts. in which Hg is preponderant, and in any case the relative amt. of the 2 cannot be estd. from the bulk of the ppt. When NH_4OH soln. is poured over the mixed chlorides, a variable portion of the Ag is reduced or otherwise retained by the ppt., the amt. being controlled by unknown factors, but the longer the soln. remains in contact with the Hg ppt. the less Ag remains in the NH_4OH soln., and Böttger's procedure of pouring the same liquid over the ppt. repeatedly makes matters worse. For the estn. of Ag, all the HgCl should be oxidized to sol. HgCl_2 , preferably with NaOCl and HNO_3 . G. W. M.

The estimation of small amounts of arsenic, with special reference to the Smith method. K. BECK AND MERREO. *Arch. kais. Gesundheitsamte* 50, 38–49(1915).—A brief summary of the principles upon which the methods of Marsh and others are based is followed by a report of experiences with the procedure as outlined by Smith (cf. C. A. 6, 3381). The authors have found the colorimetric method applicable to amts. not greater than 0.04 mg. and that it is easy to distinguish between 0.002, 0.005, 0.01, 0.02, 0.03 and 0.04 mg., as shown by the colored chart published as an illustration. If for any reason greater accuracy is desired, use the colorimetric method only as a preliminary and employing a larger quantity of material weigh the HgCl formed, or titrate the As_2O_3 . The method has been applied successfully to meat exts., gelatin, hardened oils, etc. The only alteration noted in app. and technic is the substitution of a bulb absorption vessel for the Smith-Erlenmeyer. H. M. LANCASTER.

The determination of antimony in the products obtained by roasting stibnite. W. T. HALL AND J. BLATCHFORD. *Bull. Am. Inst. Mining Eng.* 1916, 99–101.—*Total Sb.* Dissolve by boiling 0.25 g. with 40 cc. concd. HCl , 2 g. KI and 4 g. tartaric

acid. The large end of a CaCl_2 tube is loosely inserted in the throat of the flask to act as a trap. Boil gently for a few minutes, cool under the tap, remove free I by cautious addition of $\text{Na}_2\text{S}_2\text{O}_3$, nearly neutralize with NH_4OH , then pour the slightly acid soln. into 200 cc. of NaHCO_3 soln. and titrate with 0.1 N I and starch. Det. S as in mfd. irons (Blair, *Chem. Analysis of Iron*, 7th Ed., p. 60) by boiling with strong HCl and passing evolved H_2S into Cd soln. etc. To the Sb soln. from this operation, add 4 g. tartaric acid, dil., nearly neutralize with NH_4OH , pour into soln. of NaHCO_3 and titrate with 0.1 N I. The difference between Sb thus found, and total Sb, represents Sb present in pentad form. From these data calc. Sb_2S_3 , Sb_2O_3 , and Sb_2O_5 , assuming that $\text{Sb}_2\text{O}_3 + \text{Sb}_2\text{O}_5 = 2\text{Sb}_2\text{O}_4$.

E. WALLER.

Dissolved gold in slime residue. L. R. BENJAMIN. *J. Chamber Mines W. Australia* Sept., 1914; *J. Chem. Met. Soc. S. Africa* 15, 337-42; *J. Soc. Chem. Ind.* 34, 965.—The proportion of dissolved and undissolved Au in slime residues is best ascertained by filtering and assaying the soln., and calcg. the dissolved Au from the proportion of soln. to dry slime. The undissolved Au is found by difference, after detg. the total Au content in the dried material. In the latter assay, the usual practice of drying the pulp over a fast fire leads to low results, ascribed chiefly to the imperfect removal from the sides of the iron dish of incrustations contg. the Au from the more concd. soln. formed during the later stages of the drying. The error is largely overcome by pptg. the dissolved Au prior to drying, by adding 10 cc. of 5% CuCl_2 soln. per kg. of pulp. After thorough stirring, the mixt. is evapd. as usual. The direct detn. of undissolved Au is untrustworthy, as the slime cake cannot be washed abs. free from sol. Au.

E. J. C.

Two analytical methods involving the use of hydrazoic acid. FRIEZ SOMMER AND HEINRICH PINCAS. *Ber.* 48, 1963-9(1915).—(1) *Detn. of HN_3* : Raschig's method which depends upon its oxidation with an excess of I_2 soln. through the catalytic action of $\text{Na}_2\text{S}_2\text{O}_4$ formed on adding a crystal of $\text{Na}_2\text{S}_2\text{O}_4$, fails with dil. solns. of HN_3 . The authors propose the use of salts of tetravalent Ce which in neutral or acid soln. react according to the equation $2\text{HN}_3 + 2\text{CeO}_2 = 3\text{N}_2 + \text{H}_2\text{O} + \text{Ce}_2\text{O}_3$. Use a 200 cc. flask with a long neck as the generator, immerse it in water of the temp. of the azotometer, insert a 30 cc. stoppered tube containing the Ce salt (2-3 g. to 0.1 g. HN_3) and after temp. equil. has been established, mix the reagent and sample by shaking. In general $(\text{NH}_4)_2\text{Ce}(\text{NO}_3)_6$ is employed but in the presence of free HCl, to avoid evolution of Cl_2 , use $\text{Ce}(\text{SO}_4)_2$ with an excess of AcONa . The authors weighed 0.06340 g. NaN_3 ; found 0.06342. (2) *Detn. of HNO_2* : With HNO_2 , HN_3 reacts according to the equation $\text{HN}_3 + \text{HNO}_2 = \text{N}_2 + \text{N}_2\text{O} + \text{H}_2\text{O}$. Add a known excess of HN_3 soln. to the nitrite, acidify it with 0.5 N acid and shake for 2 min. Make alk. with clear $\text{Ba}(\text{OH})_2$ soln., boil off N_2O and det. the amt. of HN_3 remaining by method (1). To detect HNO_2 in the presence of HNO_3 add HN_3 soln. to decompose the latter, drive off the excess, boiling until the soln. is odorless and gives no red color with FeCl_3 . Identify HNO_2 by the diphenylamine color reaction.

H. L. OLIN.

A new method for the estimation of methyl alcohol in the presence of ethyl alcohol. G. RIGF. *Arb. kais. Gesundheitsamte* 50, 50-6(1915).—The equation $\text{MeI} + \text{Me}_2\text{S} = \text{Me}_2\text{SI}$ represents a reaction taking place readily at room temp. or lower. The other alkyl halides require a much higher temp. for a similar reaction and upon this is based a quant. method. In examg. a mixt. of MeOH and EtOH the first step is to make the alkyl iodides. Place 10 cc. sample in small distn. flask kept cool by standing in ice-water. Add red P (1 cc. EtOH requires 0.18 g. P, 1 cc. MeOH 0.26 g. P). Connect with an upright condenser using a ground-glass joint and return the flask to the ice-water during the next 20 min. Add I gradually in about 3 g. portions (1 cc. EtOH requires 2.2 g. I, 1 cc. MeOH 3.18 g. I). Control the reaction by cooling the flask in

the bath. When I is all added place the flask on an unheated water bath and connect the upper end of the condenser with a bulb tube dipping into KOH. If the reaction does not start within a few minutes, heat the bath cautiously with a small flame. Keep the liquid in the flask in steady ebullition by cooling in ice-water or heating as required. When the HI is all off (1-1.5 hrs.) allow the flask to cool and disconnect the condenser. Place the condenser in an inclined position and distil off the MeI and EtI, using as a receiver an 80-cc. sepg. funnel containing 10 cc. cold H₂O. In the distn. raise the temp. gradually and distil off the first portions slowly. To drive over the last traces raise the temp. of the upper part of flask by wrapping it in a towel. This distn. usually requires about one hr. To the iodides in the sepg. funnel add 15 g. KOH (10%) soln. well cooled. Shake about 50 times and allow to stand about 15 min. Remove the supernatant liquid with a pipet. Wash twice more using 40 cc. cold H₂O. Allow the clear colorless iodides to stand with the last wash water overnight or for 4 hrs. at least, in an ice bath. Then pour into a weighed measuring cylinder with ground-glass stopper. From the wt. and vol. of the iodides it is possible to judge approx. the Me content. If MeI content is less than 5% add 0.5 cc. dry Et₂O as this assists in preventing formation of Et₃SI. If larger amts. of MeI are present it is not necessary to add Et₂O. To an aliquot of the iodides (2 cc.) in a 20 cc. flask add 2 cc. Me₂S, if the MeI is over 5%. If not, add 1.5 cc. Me₂S and 0.5 cc. Et₂O. Close with a cork stopper and allow to stand in a closed desiccator for 20-24 hrs. at 19-20°, or the mixt. may be sealed in a glass tube and left in an incubator at 19° for 20 hrs. Rinse out the Me₂SI with Et₂O previously dried and distd. from metallic Na. Transfer ppt. quantitatively to a stoppered flask, dissolve in H₂O and titrate with N/1 or 0.1 N AgNO₃ according to amt. present. Add the AgNO₃ gradually with shaking to slight excess (shown by greenish coloration), titrate back with NH₄CNS and Fe alum. One mol. AgNO₃ = 1 mol. Me₂SI = 1 mol. MeOH. The Me₂S should be kept in sealed tubes in a cool, dark place because of its unpleasant odor. Filtration and washing is best conducted in the open air. Residues should not be thrown out but should be destroyed with fuming HNO₃. In 10% mixts. contg. 2, 0.5, 0.20, 0.20, 0.10% MeOH, the remainder of the 10% being EtOH, the following respective amts. were found: 1.87, 0.56, 0.27, 0.20, 0.21, 0.13. Detailed procedures are also given for the estn. of MeOH in brandy. H. M. L.

The determination of reducing sugars. A volumetric method for determining cuprous oxide without removal from Fehling solution. F. M. SCALES. U. S. Dept. Agr., Bur. Plant Ind. *J. Biol. Chem.* 23, 81-7 (1915).—In this method the Cu₂O is converted into Cu₂Cl₂; a definite vol. is pipetted into I soln. and the excess of I is titrated with Na₂S₂O₃ soln. Mix 25 cc. each of the Cu portion (34.639 g. of CuSO₄·5H₂O in 500 cc. of H₂O) and the alk. portion (173 g. of Rochelle salts and 50 g. of NaOH in 500 cc. of H₂O) of Fehling soln. in a 400 cc. Jena beaker, add the sugar soln. and make up to 100 cc. Cover with a watch glass and heat on an asbestos mat with a flame regulated so that boiling begins in 4 min. Boil for 2 min. As soon as the Fehling soln. is placed over the flame, measure approx. 250 cc. of distd. H₂O into each of two 500 cc. Erlenmeyer flasks and add 25 cc. of 0.05 N I soln. (6.5 g. of resublimed I and 9 g. of KI per l.) from a pipet with a mark on the tip at a point where the soln. stops, so that exactly the same vol. may be measured each time. Seal the flasks with rubber stoppers. Place a 75 mm. funnel with a long stem in a 200 cc. volumetric flask which should be marked to contain and should be cut off about 20 mm. above the mark; the edge is polished and flared so that a rubber stopper may be pressed down to within 12-14 mm. of the mark. Add 15 cc. of concd. HCl and 15 cc. of H₂O at 80-95° just before the boiling of the Fehling soln. is completed. The tip of the funnel must be below the surface of this soln. After the Fehling soln. has boiled for 2 min., bring the ppt. into suspension by agitating the soln. and pour it rapidly onto the funnel.

Wash the beaker, watch glass and funnel with hot H_2O and fill the flask to the mark. Insert the rubber stopper and distribute the contents evenly by tilting the flask back and forth 5-6 times. Pipet 50 cc. of the mixed soln. into each of the flasks containing the I soln. A one-holed rubber stopper with a vent in the side should be slipped onto the 50 cc. pipet in such a way that the tip of the pipet will be about 1 cm. below the surface of the 275 cc. of soln. when the stopper is in the 500 cc. Erlenmeyer flask. Agitate the Erlenmeyer flask to prevent the formation of a ppt. by an excess of acid accumulating in one place. As the soln. drains down, draw out the stopper and tilt the pipet so that the contents run out slowly. Withdraw the pipet as soon as the soln. reaches the mark on the tip. Seal the flask with a rubber stopper. Titrate the excess of I with 0.05 $N Na_2S_2O_3$ soln. (standardized against 0.05 $N K_2Cr_2O_7$ soln.), adding 2 cc. of starch soln. when the end point is nearly reached. Multiply the difference between the number of cc. of 0.05 $N Na_2S_2O_3$ soln. oxidized by 25 cc. of I soln., as detd. by the standardization, and the number of cc. acted upon by the I remaining after the addition of the Cu_2Cl_2 soln. by 14.315 to obtain the mg. of Cu_2O in the whole soln. Amts. of dextrose from 4 to 150 mg. may be detd. by these 0.05 N solns. and amts. up to the limit of the Fehling method can be detd. by taking a smaller quantity of the Cu_2Cl_2 soln. or by changing the strength of the reagents. A single detn. can be made in 20 min. The method yields results fully as accurate as those of the standard gravimetric method. The method may be used for the quant. detn. of Cu by reducing the Cu in an alk. soln. with dextrose. Dextrose, maltose, lactose and invert sugar may be estd. by the method.

A. P. LOTROP.

Estimation of thiophene in benzene. PAOLINI AND SILBERMAN. *Rend. accad. Lincei* 24, 209-11(1915); through *Ann. chim. applicata* 4, 289.—Thiophene in C_6H_6 is detd. in the form of the tetra-Hg acetate. A little more than the calcd. quantity of HgO is dissolved in twice its wt. of glacial $AcOH$, and the Hg acetate allowed to settle. Then the C_6H_6 contg. the thiophene is added, and the liquid heated on the salt bath with reflux condenser for 15 min. After cooling, the ppt. of thiophene tetra-Hg acetate is collected. This compd. is insol. in all solvents, except warm glacial $AcOH$, in which it dissolves in the proportion of 1:5.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Microscopic tests on opaque minerals. EVEREND L. BRUCE. *School Mines Quart.* 35, No. 3; *Chem. News* 111, 121-2(1915).—B. discusses the prepn. of the sample, the instruments used, and the methods employed for examn. The latter consist in first noting color and appearance, and then etching with cold HCl ; if unattacked, cold HNO_3 is used; finally, if the substances resist both single acids, aqua regia is used. The chief reactions employed are given, and also an outline of a determinative scheme.

J. H. BOWER.

The problem of the diamond. E. BAUR, K. SICHLING AND E. SCHENKER. *Zürich Z. anorg. allgem. Chem.* 92, 313-28(1915).—Calcs. based on Roth's value of the heat of transformation of diamond to graphite indicate that the pressure on the curve in the P - T projection representing the "the 2 forms increases with increasing temp. at such a rate that there may be a stable form in the earth's crust. Since diamonds are not found, it is probable that the ex-

ever be a stable form in the
 ons after the diamond are
 ich the diamond is stable,

and hence the P - T curve probably does not have the above form. By making appropriate assumptions, the equation for a curve with a max. at 2300° abs. and 35000 atms. is calcd. for the above equil. By making the necessary assumptions in regard to the rise in temp. with increasing depth, it is calcd. that the conditions necessary for the formation of diamonds would be found at 3000° and 100 kilometers depth; the mechanism by which the diamonds thus formed were brought to the surface is probably the geologic process by which the South African "pipes" were formed. A number of attempts to prepare diamonds at ordinary pressure with thermite charges containing C and a silicate mixt. with FeO and CaC_2 in an atm. of CO, and with $\text{Na}_2\text{B}_4\text{O}_7$ melts containing CaC_2 or SiC in an atm. of CO, and at high pressures (8000 atm.) with various melts containing FeO, CaC_2 and SiC all gave negative results.

GEORGE W. MORREY.

The hardness and microstructure of fusions of tellurium and sulfur compounds.

P. SALDAU. *Ann. inst. mines Petrograd* 4, 228-37(1913); *Neues Jahrb. Min. Geol.* 1915, II, Ref. 21.—The hardness of altaite (PbTe), 31.85 kg. per mm^2 , exceeds that of the components, Pb 3.92 and Te 18.43 kg. per mm^2 . A max. in the hardness curve occurs at 49.8 atomic % Te. Solid solns. of Pb in PbTe occur up to 5 atomic % Pb; they are absent in PbTe + Te. PbS forms solid solns. in FeS, Ag_2S and Cu_2S up to 2% by wt. PbS and PbTe do not form a continuous isomorphous mixture series.

E. T. W.

Ilmenite from Val Devero (Ossola). ANGELO BIANCHI. *Rend. accad. Lincei* 23, 722-7(1914); *Neues Jahrb. Min. Geol.* 1915, II, Ref. 22-3.—The mineral, which occurs in chlorite schist and wehrlite, is described crystallographically. E. T. W.

Studies in the magnesian silicates. The group of zillerite, zermattite and palygorskite. A. FERSMANN. *Mem. acad. sci. Petrograd* 32, No. 2, 430 pp.(1913); *Neues Jahrb. Min. Geol.* 1915, I, Ref. 312-29.—A report of an investigation which has extended over several years, in which many samples of "mountain-leather" and similar substances from all possible sources have been carefully purified by hand picking, and analyzed. The problem was to characterize the mineral species represented from the physico-chem. standpoint, to throw light on their genetic relations with other species, to improve their nomenclature and to establish their correct classification. The question of natural decomposition products is discussed at length. Two new structural terms are defined: pilolitic, referring to irregularly matted fibers, and neurotic, to parallel fibers. The minerals are classified into: Zillerite group: tremolite-zillerite and actinolite-zillerite; serpentine-mountain cork group: zermattite and schweizerite (the latter with Fe replacing some Mg); Al-palygorskite group: paramontmorillonite, $\text{H}_{10}\text{Al}_2(\text{SiO}_4)_4$, lassalite = α -palygorskite, $\text{H}_{10}\text{Mg}_2\text{Al}_4(\text{SiO}_4)_{11}$, β -palygorskite $\text{H}_{18}\text{Mg}_3\text{Al}_3(\text{SiO}_4)_7$ (the most stable mineral; has a Ca-analog); α -pilolite, $\text{H}_{20}\text{Mg}_4\text{Al}_2(\text{SiO}_4)_{10}$, β -pilolite, $\text{H}_{24}\text{Mg}_6\text{Al}_3(\text{SiO}_4)_{11}$, parasepiolite, $\text{H}_2\text{Mg}_2(\text{SiO}_4)_3$ and the Fe-palygorskite-xylolite group, with formulas corresponding to some of the above, with Fe replacing Al. An exhaustive review of the literature and a historical discussion is then given. The methods of investigation are also described. The deposits of these minerals in Russia are discussed in detail. They occur mostly in connection with magnesian limestones and marls, and are believed to have been formed by atmospheric decompn. of clays, and reactions between liberated Al_2O_3 and SiO_2 gels and the carbonates. Deposits in western Europe are then taken up, then those in Austria and adjoining countries, and those of other continents; the U. S. occurrences belong almost entirely to the palygorskite group, parasepiolite being especially widely distributed. The compns. and origins of each of the species recognized are then discussed. The first 2 groups (cf. list at forms of well known minerals. The palygorskite group is very important role in the zone of weathering and being especially

stable. A table is given showing the theoretical formulas and compns. of the members of this and the xylotile group, and compared with the results of 41 old and 22 new analyses, good agreement being found, except as to H_2O content in a few cases. The constitution of the palygorskites can only be explained by assuming the existence of aluminosilicic acids, the nucleus being $H_3Mg_2(SiO_4)_3$ with an aluminosilicate, $H_{10}Al_2(SiO_4)_4$, as addition product; the ratios between this and side chains are found to be small integers, frequently 1. Some isomorphous mixture occurs between different members. H_2O is present in 3 different forms: constitutional, zeolitic, and absorbed. With increase of Al content the decomposibility of these minerals by acids and bases decreases. For β -palygorskite $n = 1.55$; and with increasing MgO -content this increases. The double refraction is $0.015-0.020$, this also increases with the Mg. An elaborate table of the properties, genesis, etc., of the minerals is given. The Fe-palygorskite or xylotile group is discussed in like manner. The n 's and double refractions are higher than in the corresponding Mg minerals. Chapters are also added on the general characters and classification of pilolitic asbestos, and on the identification of the various minerals. Staining expts. with acid-fuchsin, methylene-blue, methylene-green, and methyl orange were found to be of use in the latter connection. Some of F.'s analyses have been previously published (cf. *C. A.* 8, 647; Doelter's *Handbuch Min. Chem.* 2, 378, 434, and 609); 37 additional ones are here given. R. T. W.

Potassium salts. An economic geological study. E. MACKAY HERIOT. *Eng. Mining J.* 100, 660-72, 712-4 (1915).—H. describes the known K deposits, shows that the only considerable source is marine depositions, in the form of beds of Tertiary or earlier age, and points out that the chance of finding new deposits is good. W. B. H.

The potash deposits of the Sand Hills region of northwestern Nebraska. VICTOR ZIEGLER. *Colo. School Mines Quart.* 10, No. 3, 6-26 (1915).—The history, topography, climate and general geology of the region are described, and a detailed account of the numerous lakes given. The larger lakes are fresh, the smaller ones in part highly saline, as shown by detns. of the salts listed; and the K_2O of content of the salts is high, often exceeding 10 and in one case 35%. Complete analyses given for several lakes show the salts to be largely carbonates and sulfates of Na and K. The source of these salts is believed to be chiefly the ashes of forest and prairie fires, carried by surface waters into lakes without outlet and concd. by gradual evapn. In analyses of the ashes of grasses K is higher than Na, whereas in the lakes the reverse is true, but it is thought that the excess Na has been contributed by the surrounding sediments, through leaching by rain water. An account is given of the method of commercial exploitation of the deposits of Jesse Lake; the process consists in submitting the water to solar evapn., and concg. the brines with steam heat. The K and Na salts are not sep'd. at present, the mixt. of the two being used as fertilizer. This lake probably contains over 100,000 tons of salts, and although no large accumulations of salines can be expected in the district, it is thought that other plants could be made profitable if located so as to draw water from groups of the smaller lakes. E. T. W.

The origin of petroleum and asphalt. CLIFFORD RICHARDSON. *J. Ind. Eng. Chem.* 8, 4 (1916).—The theory is suggested that petroleum and asphalt form by surface action between natural gas and colloidal "sands." The character of the petroleum will depend on the nature of the gas and on that of the "sand." If the gas contains S, a S petroleum will result; if the "sands" contain S, a different type of S petroleum may result, the difference between Trinidad and Mexican petroleum being thus explained. Colloidal sand, being more active, would produce asphaltic petroleum whereas a true sand with less surface action would produce a paraffin petroleum.

F. M. ROGERS

The correlation of potassium and magnesium, sodium and iron, in igneous rocks. HENRY S. WASHINGTON. *Proc. Nat. Acad. Sci.* 1, 574-8(1915).—W. claims that the view that in igneous magmas K and Mg on the one hand, and Na and Fe on the other, tend to vary together, is greatly strengthened if not quite established by cumulative evidence of two kinds: mineralogical and petrographical. A number of examples are given, and the relation is further brought out by plotting $\text{Na}_2\text{O}-\text{K}_2\text{O}$ against $\text{FeO}-\text{MgO}$. J. H. BOWER.

The loess of the Argentine pampas formation. W. MEIGEN AND P. WERLING. *Ber. naturf. Ges. Freiburg* 21, 1-26; *Chem. Zentr.* 1915, II, 433-4.—The authors give the varied mechanical and chem. analyses of the Lehman-Nitsche loess tests. For detn. of solubility in acids the sample was digested in 5% HCl and the residue from the soln. of sepd. SiO_2 treated with NaOH and finally with HCl. Since the alkalies in the different samples were always detd., the 3 filtrates from the analysis could be combined. For the detn. of the solubility in alkalies the sample was heated for 1½ hrs. on the water-bath with 100 cc. of 5% NaOH. The analyses (which are reported in the original) show that all samples of loess from Córdoba were considerably coarser grained than the German loess. It shows traces of carbonates whereas the German loess contains 25-30%. This may have its basis in the original material. The Argentine loess has a larger content of alumina and a greater solubility in HCl than the German which points to an irregular original material and to a greater, more lateritic decompn. On the whole, the analyses confirm Doering's supposition that the Argentine loess owes its origin essentially to great volcanic ash showers. J. H. BOWER.

Basal Kalevien formations of Mölönjärvi. W. W. WILKMAN. *Bull. Comm. Geol. Finland* 1915, No. 43, 32 pp., with 4 p. summary in French.—Chiefly geological. A talc-magnesite is described composed of the minerals in nearly equal proportions, with small amts. of calcite, chlorite, magnetite and chromite. The serpentines are produced by decompn. of peridotite, the metabasites are metamorphic derivatives of gabbro, while the talc-magnesites constitute the final product of the disintegration of serpentine rocks. The various formations are regarded as products of dynamic metamorphism. R. L. SIBLEY.

Chemistry of sandstone weathering on the Cologne dome. R. E. LIRSEGANG. *Der Steinbruch* No. 13-4, 1-7; *Chem. Zentr.* 1915, II, 443.—L. rejects the explanation that the origin of the scaly crusts on the Cologne dome is due to the presence of layers of Ca and Mg sulfates. The "rhythmic crystn." is only possible by intermediate soln. through the presence of bicarbonates. L. W. RIGGS.

Tellurides of silver and gold (PELLINI) 6. Studies of the imperfect crystals formed in a colloidal medium (MARY) 2.

Flotation test tank for mill or laboratory. ANON. *Met. Chem. Eng.* 14, 112 (1916).—The app. is practically a small Parral tank, with a central cylinder acting as a filler to reduce the capacity. A baffle is so placed as to deflect the froth from the surface into a receiving box at one side, making use of the circular motion of the pulp

produced by the Parral system of agitation. Drawings are given of an app. to take 100 lbs. of ore. Patent rights to the system are waived when used for testing purposes.

W. L. BADGER.

Influence of heat in cyaniding gold ores. E. A. WRAIGHT. *Inst. Mining and Metallurgy, Bull.* 135, 1-18(1915).—From parallel expts. in extg. 60-mesh, 4-oz. Au ore with 0.40% KCN solns. W. concludes that heating is of doubtful value. Extn. may be increased for a short period but the rise in solubility of other minerals results in loss of KCN with a consequent decrease in soln. of Au. While the addition of O_2 in a more active form, either as H_2O_2 or in heated air, raises the solvent activity of cyanide solns., other oxidizing agents, e. g., $CaCl_2O$, $K_2Cr_2O_7$, etc., are either inert or positively deleterious.

H. L. OLIN.

Clay: its relation to ore dressing and cyaniding operation. A. W. ALLEN. *Inst. Mining and Metallurgy, Bull.* 135, 1-19(1915).—A. presents an extensive review of the literature of colloids and discusses the properties of clays in suspension. Ores with which clay is associated are difficult to treat and complete extn. of Au from even the finest slime is impracticable because of the absorptive effects of the colloidal particles. Clay slime therefore should not be weathered and it should be allowed an extended time of contact with wash soln.

H. L. OLIN.

The behavior of stibnite in an oxidizing roast. H. O. HOFMAN AND J. BLATCHFORD. *Bull. Am. Inst. Min. Eng.* 1916, 91-7.—Expts. were conducted in an elec. furnace with regulated temp. with ore ground to 20 mesh. Conclusions: At about 200° S begins to burn; there is sharp visible formation of Sb_2O_3 at 336°—white fumes. The formation of Sb_2O_3 proceeds slowly. All S can be eliminated at 400° without a large loss of Sb. The formation of Sb_2O_3 begins only when all S is gone. Loss of Sb increases with the temp.

E. WALLER.

Cyanide plant of the Baker Mines Co., Cornucopia, Ore. R. M. KRENEY. *Met. Chem. Eng.* 13, 947-53(1915).—K. describes the mill buildings, equipment, power, and operation. Operating data and costs are given. The total cost per ton of ore is \$2.103.

C. A. NOWAK.

Coke for the iron blast furnace. TAIZO KURODA. *J. Chem. Ind. (Japan)* 18, 668-72(1915).—K.'s experiences during a period of several years in the Imperial Steel Works have shown that good blast furnace coke should contain less than 1.0% S, 0.018% P, 9.0% ash and 4% moisture; its porosity should generally be 40-50% and the crushing strength 80 kg. per sq. cm. The importance of using coke of the right qualities in smelting iron in the blast furnace is emphasized.

E. J. C.

Utilization of blast furnace slags. E. C. BROWN. *Iron Age* 96, 1476-7(1915).—Mainly a review.

F. W. SMITHER.

Washing blast furnace gas at South Chicago. ANON. *Iron Age* 97, 53-7(1916).—High efficiencies in the blast furnace gas consumption are due to thorough washing of the gas by the Brassert 2-stage method. This system employs a single vertical tower designed to handle the entire output from one furnace. Into the lower half a heavy rain of water is introduced, and redistributed by screens, perforated trays and grids. The first rough washing takes place here. The upper section contains inclined baffles arranged to intercept the flow of the gas by means of a strong impinging action which insures a positive contact of the gas with the baffle surfaces. In the Brassert drier the gas impinges against vertical baffles which permit the intercepted water to escape promptly.

H. L. OLIN.

Metallurgy at the plant of Sons of Gwalia, Australia. A. WAUCHOPE AND THOMAS B. STEVENS. *Met. Chem. Eng.* 13, 925(1915); 14, 106-7(1916).—A description of a

plant working \$7.50 Au ore by all sliming treatment, with flow sheets and cost and efficiency data.

H. L. OLIN.

High and low sulfur in basic steel. J. S. UNGER. *Iron Age* 97, 146-50 (1916).

—The purpose of the investigation was to prepare steels of different degrees of hardness, each containing varying amts. of S, then work these steels into finished products and exam. them carefully during the manuf. and after completion for differences in quality. The expts. are reported in detail with numerous illustrations and tables. In practically every case finished articles in common everyday use were made; the work was carried out by the ordinary methods practiced, and in such sizes as are manufd. in the mills or shops. The author does not advocate paying no attention whatever to S content of steel, but believes that a steel containing less than 0.100% is not necessarily bad, and that it will show little, if any, difference in quality when compared with the same steel of much lower S, other conditions being the same. F. W. SMITHER.

The microchemistry of corrosion. IV. Gun metal. C. H. DESCH AND H. HYMAN.

Univ. of Glasgow. *J. Inst. Metals* (advance copy) 12, 11 pp. (1915); cf. *C. A.* 7, 3956; 9, 432, 1294.—Alloys of (1) 88 Cu, 10 Sn, 2 Zn and (2) 84 Cu, 14 Sn, 2 Zn were electrolytically corroded in NaCl soln. at various voltages between the sample as anode and Pt as cathode. Polished samples gave inconsistent results and it was found that to eliminate errors due to the flow of the surface in polishing, it was necessary to remove the flowed layer by etching in acid soln. of FeCl₃. Alloy 1, moderately slow-cooled, contained α - and very slowly cooled $\alpha + \delta$ -metal; alloy 2, slow-cooled, $\alpha + \delta$ -metal and quenched from 800°, $\alpha + \beta$ -metal. The sample showing pure α -metal was slightly more corroded than the others, which differed but little. The total corrosion is less than in brasses as a coating of basic tin salts is formed which protects the surface. H. W. GILFILL.

Physico-chemical studies of the roasting process (REINDERS) 2. Alloy of manganese and bismuth (PARRAVANO) 6. Determination of antimony in the products obtained by roasting stibnite (HALL) 7.

Treating ores. GRAF B. SCHWERIN. *Brit.*, 19,313, Sept. 1, 1914. Prior to the magnetic concn. of ores, an acid or alk. electrolyte is added to a slime in order to loosen the close adhesion to each other of the constituents of the suspended composite particles and facilitate the settling of the ore particles.

Working ores and furnace products. GEBR. BORSCHERS. *Ger.*, 285,791, Aug. 9, 1911. The process is suitable for ores and materials containing Co, Ni, and Ag, together with Fe and As, as well as speiss and Ni-Co oxides. These materials are roasted with alkali bisulfate. See *Brit.*, 18,276, 1912 (*C. A.* 8, 317).

Concentrating ores. L. BRADFORD. *Brit.*, 19,844, Sept. 18, 1913. In the sepn. of metallic sulfides by selective flotation processes, such as are described in 21,104, 1913, (*C. A.* 9, 593) a soln. of one or more substances such as sulfites or thiosulfates of alkali metals or SO₂ is added to the medium before the flotation is effected, with the object of retarding the flotation and avoiding the tendency of the particles of one sulfide to agglomerate and include particles of another sulfide.

Concentrating ores. MINERALS SEPARATION and DE BAVAY'S PROCESSES AUSTRALIA PROPRIETARY, LTD. *Brit.*, 19,373, Sept. 2, 1914. Mixed PbS and ZnS ores, particularly slimes, are sepd. by subjecting them to a froth-flotation process in the presence of or after preliminary treatment with an amt. of H₂SO₄ less than that required to float both the Pb and the Zn and with or without a frothing or emulsifying agent, sepg. the resulting froth containing the PbS, and thereafter, if necessary,

submitting the tailings to a froth-flotation process for the flotation of the Zn. Cf. C. A. 9, 2220.

Concentrating ores. MINERALS SEPARATION and DE BAVAY'S PROCESSES AUSTRALIA PROPRIETARY, LTD. Brit., 19,374, Sept. 2, 1914. Mixed PbS and ZnS ores, particularly slimes, are sepd. by subjecting them to a froth-flotation process in the presence of an amt. of a frothing agent not more than that required for the flotation of the PbS only, and thereafter, if necessary, submitting the tailings to a further froth-flotation process with an increased quantity of frothing agent for the flotation of the ZnS. The process may be applied in the presence of the salts mentioned in 11,939, 1913 (C. A. 8, 3552).

Concentrating ores. A. H. HIGGINS and MINERALS SEPARATION, LTD. Brit., 19,855, Sept. 16, 1914. Products obtained by treating organic substances such as fats, oils, alcs., phenols, or their homologs with H_2SO_4 are employed as frothing agents in froth-flotation processes of ore concn. The use of a product obtained by adding 5 g. of β -naphthol to 10 g. of concd. H_2SO_4 while stirring in a water-cooled vessel is described.

Concentrating ores. MINERALS SEPARATION, LTD. Brit., 19,856, Sept. 16, 1914. Products obtained by treating hydrocarbons, particularly unsatd. hydrocarbons, with H_2SO_4 are employed as frothing agents in froth-flotation processes of ore concn. Acid sludge obtained in refining hydrocarbons may be used. The products may be allowed to stand for some time before use or may have been mixed with H_2O for some time. Cf. C. A. 10, 169.

Ore-roasting furnace. K. J. BRSKOW and A. RAMEN. U. S., 1,166,654, Jan. 4.

Apparatus for calcining, desulfurizing and agglomerating ores. F. MEYER. U. S., 1,166,142, Dec. 28.

Furnace for smelting iron ore. C. K. DAVIS. U. S., 1,165,393, Dec. 28.

Extracting metals; furnaces. G. GRÖNDAL and H. NILSSON. Brit., 20,361, Sept. 30, 1914. Fine Fe or other ore to be agglomerated, with or without reduction, is packed into receptacles open at both ends which are arranged one against the other so as to form a long chamber through which hot gases from a burner are passed, the ore masses being formed with passages to allow this. When the receptacle next to the burner chamber has been sufficiently heated, it is transferred to the other side of such chamber and is then traversed by the air or gas for combustion, which is thus heated, a fresh receptacle being added at the other or chimney end. Where the ore is to be oxidized, air is supplied at a suitable point and gas enters the burner chamber directly, but where the ore is to be reduced, the gas and air supplies are exchanged. Instead of a gas, powdered fuel may be used. The burner chambers are similar in shape to the ore receptacles and have openings which are closed when the chamber is not in the "burner" position.

Sintering flue dust. S. W. OSGOOD. U. S., 1,166,927, Jan. 4. Flue dust from blast furnaces is mixed with CaO and H_2O and the mixt. is formed into pellets or globules, dried and sintered in a reducing flame.

Agglomerating ores. P. O. HARDING. U. S., 1,166,903-4, Jan. 4. The ore, *e. g.*, fine Fe ore or flue dust is passed downward through a combustion zone and as it falls below the combustion zone, broken and treated with a current of air to carry back the friable unchanged portions to the combustion zone where they are ignited and agglomerated.

Briquetting ores before smelting. O. BALTIN. U. S., 1,166,171, Dec. 28. The ore is mixed with gypsum and pitch and the mixt. is compressed into briquets for

smelting. By using gypsum as binder, less pitch is required and the amt. of noxious fumes from smelting decreased.

Smelting complex sulfide ores. F. W. HIGHFIELD. U. S., 1,167,176, Jan. 4. Sulfide ores of Zn, Pb, Fe, Cu and Ag are roasted to remove S, mixed with reducing material and heated in an elec. furnace in a reducing atm. to about 950° to volatilize the Zn without volatilizing the Pb. The molten Pb is sepd. from the residual mat and the latter is heated electrically to 1350° to form silicious slags; the liquid mat of Cu and Fe sulfides is treated with a d. c. to decompose Cu and Fe sulfides and promote sepn. of Cu and Fe. Cf. C. A. 9, 2353.

Reducing iron ores. E. B. PRATT. U. S., 1,167,016, Jan. 4. Ore is heated to a reducing temp. with H, in the absence of any oxidizing gases and with just sufficient C to give the desired C content in the metal produced and the temp. of all parts of the charge is so regulated as to effect reduction of Si in the ore or added flux such as to give the desired proportion of Si in combination with the Fe.

Puddling iron. G. A. JARVIS. Brit., 20,163, Sept. 25, 1914. Non-phosphoric Fe is puddled in an acid-lined furnace with additions of an acid silicate of Fe to obtain a malleable and fibrous product. Dephosphorized metal from the basic open-hearth may be used, such metal being recarburized, if necessary, and after starting the process, the silicate of Fe employed may be the slag resulting from the process, with the addition of hammer or mill scale.

Retorting impure zinc ore. C. A. H. DE SAULLES. U. S., 1,166,447, Jan. 4. The front portion of a retort or muffle is filled with a briquetted charge of ore which is low in Fe and Pb, mixed with coal or coke which serves to filter out Fe and Pb from the main portion of the charge which is placed in the rear of the retort or muffle.

Extracting zinc from ores. O. BALTIM. U. S., 1,166,170, Dec. 28. Zn ore is reduced after forming into rounded briquets with reducing material, the briquets being placed in a reducing chamber so that they contact with each other at only a single point and have almost their entire surface exposed to the direct action of the heat.

Pure zinc oxide; pure zinc. H. WILLIAM BARON DE STUCKLÉ. Ger., 285,617, Dec. 8, 1912. Pure ZnO or metallic Zn may be obtained by treating purified solns. of Zn salts with $(\text{NH}_4)_2\text{SO}_4$, with regeneration of the sulfite and ignition of the resulting ZnSO_4 . See Fr., 465,816 (C. A. 8, 3415).

Recovery of zinc. E. GELLBACH and M. MATT. Ger., 285,866, May 11, 1913. Zn or other volatile metals are recovered from briquetted poor pulverulent materials in the blast furnace, by mixing the material directly with the required amt. of coke or coal powder, introduced preferably with the blast, whereby no binder is required for the briquetting process.

Separating cobalt from speiss. P. M. McKENNA. U. S., 1,166,067, Dec. 28. Speiss containing Co and Ni is fused with B_2O_3 about equal in wt. to the Co in the speiss and a gravity sepn. is effected between the speiss and the boric Co slag formed. The latter is then heated to about 1000° in an oxidizing atm. to expel As and Sb. The Fe present may be removed, if desired, by melting with SiO_2 as a preliminary operation.

Purifying metallic bismuth. W. C. SMITH. U. S., 1,166,721, Jan. 4. Metallic Bi carrying impurities such as Cu, Pb, Te, Ag, Au, As and Sb is treated, while molten, with S to eliminate As, Sb and Cu, which are removed by skimming. The molten residue is treated with NaOH and skimmed to remove Te together with As, Sb and S remaining from the previous treatment. Then Zn is dissolved in the molten residue and Cu, Ag and Au are removed by cooling and skimming. Zn is removed by treatment with NaOH and skimming and the Bi is freed from Pb by crystn.

Castiron molds. A. S. REEDER. U. S., 1,166,934, Jan. 4. Cast-Fe molds, *e. g.*, for use in molding glass, are freed from strain after casting by gradually heating to 760° or higher and the mold is finished after gradual cooling.

Pouring a series of molds. F. DAHL. Ger., 285,469, Dec. 24, 1912. The construction and operation of a traveling sepg. device for the liquid metal.

Galvanizing iron. E. BROEMME. Ger., 285,923, Oct. 30, 1913. The etching preliminary to the coating with Zn is effected by treating the Fe articles with a soln. mixt. of alkali hydrogen sulfate and alkali chloride, especially NaCl. By employing these substances to remove the rust, FeSO₄ and Na₂SO₄ are obtained as by-products and may be sepd. by fractional crystn. However, the mixt. may be evapd. and ignited, and after cooling the Na₂SO₄ may be washed out, leaving the Fe₂O₃ as a crude powder suitable as a pigment. *E. g.*, NaHSO₄ 120 kg. and NaCl 60 kg. are dissolved in warm H₂O, and the Fe to be treated is passed through the soln. slowly. A violent reaction results, with a marked rise in temp., the resulting HCl, in the nascent state, being much more active than ordinary HCl. Further, the H liberated exerts a strong reducing action, so that a clean metallic surface is obtained in a much shorter time than by acid treatment. After drying in the air the surfaces are ready for coating.

Alloy for electric contact points. P. R. HEVL. U. S., 1,166,129, Dec. 28. An alloy of Ag with Pd containing 40-80% of Pd is used for elec. contacts which have great resistance to spark erosion.

Alloy for making rolls. H. E. FIELD and F. C. T. DANIELS. U. S., 1,166,342, Dec. 28. A hard, tough alloy for making cast rolls for shaping metals is formed of Si 0.25-1.5%, S 0.025-0.20%, P 0.01-1.0%, Mn 1.5-3.5%, C 1.5-3.5% and Fe to make 100%.

Alkali-resistant metal vessel. B. STRAUSS. U. S., 1,166,866, Jan. 4. Vessels for boiling alkali solns. are formed of Ni steel alloy containing about 25% Ni and 0.5-2% Cr, with an oxidized surface.

Coating iron with aluminium. S. UYENO. U. S., 1,165,920, Dec. 28. Fe articles, *e. g.*, plates, are first coated with Sn and then swept with a metal brush while immersed in molten Al to remove the Sn entirely and replace it with Al. A smooth coating is produced if the sheets are passed between rollers.

Gold alloy. K. G. P. RICHTER. U. S., 1,165,448, Dec. 28. A malleable white alloy is formed of Au 57, Pd 35 and Ni 7.5 "atoms per cent."

10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

Some homologs of menthol. EYVIND BOEDTKER. Univ. Christiania. *Bull. soc. chim.* 17, 360-7(1915).—Alkylmenthones described by Haller (*Compt. rend.* 138 1139), when treated with Na in Et₂O satd. with H₂O, gave rise to the corresponding alkylated menthols. *Methylmenthol*, C₈H₁₈.CHMe.CHOH, *b_m* 129-30°, *d₄¹⁸* 0.9124

n_D²⁰ 1.4692, [*α*]_{D²¹} (C₆H₆) -2° 26', possessing a camphoraceous odor; *acetate*, *b₁₇* 125°, *d₄¹⁸* 0.9313, *n_D²⁰* 1.4578, [*α*]_{D²²} (C₆H₆) -18° 7', possessing a sharp odor; *ethylmenthol*, *b₁₈* 124°, *d₄¹⁸* 0.9246, *n_D²⁰* 1.4769, [*α*]_{D²²} (C₆H₆) 4° 55', possessing a camphor-like odor; *acetate*, *b₁₄* 131-2°, *d₄¹⁸* 0.9366, *n_D²⁰* 1.4636, [*α*]_{D²¹} (C₆H₆) -6° 6'; *propylmenthol*, *b₁* 141-5°, *d₄¹⁸* 0.9075, *n_D²⁰* 1.4675, [*α*]_{D²²} (C₆H₆) 29° 7'; *acetate*, incompletely purified *b₁₀* 152°, *d₄¹⁸* 0.9515, *n_D¹⁹* 1.4741, [*α*]_{D²²} -8° 58'; *isoomylmenthol*, *b_m* 150°, *d₄¹⁸* 0.8985, *n_D²⁰* 1.4661, [*α*]_{D²²} (C₆H₆) 33° 44'. *Benzylmenthol* [cf. Wallach, *Ann.* 305, 263; Semmler, *Ber.* 1904, 236], *b_m* 203-5°, *d₄²⁰* 0.9819, *n_D²⁰* 1.5257, [*α*]_{D²⁰} (C₆H₆) -43° 19', *w_m*

formed by reducing benzylidenementhone in Et_2O , satd. with H_2O , with Na. *Benzylmenthone*, b_p 177°, d_4^{18} 0.9979, n_D^{19} 1.5232, $[\alpha]_D^{23}$ (C_6H_6) 28° 4', was prepd. by treating menthone in Et_2O with NaNH_2 , heating to remove the NH_3 , and subsequently adding PhCH_2Cl .

LOUIS E. WISE.

Benzylidenementhones. EYVIND BORDTKER. *Bull. soc. chim.* 17, 374-80(1915).

—Benzylidenementhone hydrochloride (A) whose constitution has hitherto been uncertain (cf. Wallach, *Ann.* 305, 261; Martine, Thesis, "Study of the Menthones," Paris, 1904), when treated with PhH in the presence of AlCl_3 , yielded a menthodiphenylmethane, m. 159° (identical with the compd. previously reported, m. 160.5-1.5°; cf. C. A. 6, 1133). (A) therefore has the constitutional formula $\text{CO.C}_6\text{H}_{16}\text{CH-}$

CHPhCl . A by-product of the above reaction was a stereoisomeric menthodiphenylmethane, m. 135-6° (previously formed by the action of PhMgBr upon benzylidenementhone (B)). Martine's work on the condensation of menthone with BzH and HCl was repeated and his results were confirmed. B. thus obtained a 75% yield of (B) and 25% of a Cl-containing oil (C), which could not be crystd. When (C) was heated under reflux with alc. KOH, the alc. removed by distn., the residue poured into H_2O and extd. with Et_2O , the ext. dried, and the Et_2O removed, B. obtained α -benzylidenementhone (D), d_4^{19} 1.0105, n_D^{20} 1.5403, $[\alpha]_D^{21}$ (in C_6H_6) -82° 23', not solidifying -18° and stereoisomeric with (B) (which according to M. is itself a mixt. of 2 isomers). Apparently (C) is a mixt. of isomeric benzylidenementhone hydrochlorides. When treated with KCN in alc. (A) and (C) both yielded the same series of nitriles (type formula: $\text{CO.C}_6\text{H}_{16}\text{CHCHPhCN}$, but not further characterized). The interaction of

(D) and H_2NOH led to the formation of $\text{CO.C}_6\text{H}_{16}\text{CHCHPhNHOH}$, m. 160°, pre-

viously prepd. by Wallach, M., *et al.* (D) adds HCl to form a non-crystallizable oil. When oxidized with KMnO_4 , (D) in acetone yielded largely BzOH, besides α, α' -methylisopropyladipic acid, m. 105-6°, and α -isopropylglutaric acid, m. 95-6°. Heated with alc. KOH, (D) forms menthone, BzOH, and PhCH_2OH . (D) when treated with PhMgBr and subsequently with BzCl gave rise to a new menthodiphenylmethane, m. 156-7°, isomeric with those derived from (A).

LOUIS E. WISE.

Oxidizing effect of sunlight. EYVIND BORDTKER. *Bull. soc. chim.* 17, 369-74 (1915).—A flask filled with $(\text{Me}_2\text{CHCH}_2)_2$ (A), but poorly stoppered, at the end of 15 yrs. contained, besides pure (A), about 1 g. of the compound (B), $\text{C}_6\text{H}_{22}\text{O}_6$, m. 106°, without action upon $\text{NH}_3\text{-AgNO}_3$ or Fehling soln., but giving a red color with Schiff's fuchsine reagent and giving rise to a terpene-like odor when treated with hot HCl. (B) on drying *in vacuo* loses H_2O and yields a substance with a powerful odor. (B) was not obtained by the action of H_2O_2 upon (A). The formation of (B) was somewhat accelerated (1 g. being formed in 3 years) by exposing (A) in a loosely stoppered flask to the action of direct sunlight as much as possible. (B) appears to be the ketone of a polyvalent alc., but owing to poor yields its identity was not established. Pure $\text{Me}_2\text{CH}(\text{CH}_2)_2\text{NO}_2$ when exposed to sunlight in well-stoppered bottles was gradually and partially converted into methanetetra-carboxylic acid, $\text{C}(\text{CO}_2\text{H})_4 \cdot 5\text{H}_2\text{O}$ (C), plates in the form of parallelograms, m. 132°, with the loss of H_2O ; barium salt, cryst. ppt. (C) does not reduce Fehling soln. or $\text{NH}_3\text{-AgNO}_3$. When heated on the steam bath (C) is converted into $(\text{CO}_2\text{H})_4$, and if the heating is carried further to 190°, a compd., probably tartrellic acid, $\text{C}_4\text{H}_4\text{O}_6$ (prepd. by Fremy, ref. not given), is formed, together with substances which reduce Fehling soln.

LOUIS E. WISE.

Some color reactions of triphenylmethane derivatives. E. NOELTING AND A. KNOFF. *Bull. soc. chim.* 17, 385-9(1915).—The yellow color formed when Ph_3COH

is dissolved in concd. H_2SO_4 is intensified when OH or MeO groups are introduced into the ring, and the basic properties of the mol. are accentuated. Rosolic acid, which does not ordinarily dye cotton, is fixed by tannin-treated cotton. Its hexa-MeO deriv., eupittonic acid, behaves similarly. Trianisylcarbinol (A), which is itself colorless, dyes tannin-treated cotton a deep orange. In neutral soln. (A) is fixed by silk, which remains colorless, however, until further treated with acid. An orange-yellow color then develops. Trianisylmethane dissolves in concd. H_2SO_4 with an orange color, disappearing on diln. with the pptn. of the colorless hydrocarbon. Similarly phenylanisylmethane (B), [3,4-Me(MeO) C_6H_3] CHPh (C), and [3,6-Me(MeO) C_6H_3] CHPh (D) give resp. orange, orange, and violet colors with concd. H_2SO_4 (cf. Feuerstein and Lipp, *Ber.* 35, 3252). None of these hydrocarbons dyes tannin-treated cotton. v. Baeyer and Villiger's theory that the color of hydrocarbons of this type in concd. H_2SO_4 might be due to oxidation to the corresponding carbinols is rendered untenable by N. and K.'s recovery of the unchanged hydrocarbons from their acid solns. When (B), (C) and (D) in AcOH were treated with PbO_2 , the corresponding carbinols were obtained. The deriv. of (B) dyes tannin-treated cotton a reddish orange. The (C) deriv. dissolved in H_2SO_4 with a red color and dyed tannin-treated cotton an intense red, and the (D) deriv. gave a claret-red color with H_2SO_4 but failed to dye treated cotton. (Ref. to v. B. and V.'s work, which is mentioned throughout the article, is not given.) Carbinols formed by the introduction of $p\text{-NH}_2$ and -NR_2 substituents in the Ph_3COH mol. (e. g., malachite green) react with 1 mol. of acid to form green, red, or purple salts, all of which give orange colors with concd. H_2SO_4 very similar to the color produced by Ph_3COH itself. In these cases apparently the characteristic influence of the auxochrome group is lost by the combination of the NH_2 with H_2SO_4 . Compds. formed by the introduction of simple or substituted NH_2 groups into the Ph_3CH mol. dissolve in H_2SO_4 without color. Triphenylcarbinols containing OH and simple or substituted NH_2 groups (the hydroxymalachite greens) dissolve in H_2SO_4 with a yellowish orange color. The leuco bases of these complex carbinols, provided they contain but 1 OH group, give no color with H_2SO_4 . The cumulative effect of several OH substituents was noted in the case of 3,4-(HO) $_2\text{C}_6\text{H}_3\text{CH}[\text{C}_6\text{H}_4\text{NMe}_2]_2$, which gives a faint color with H_2SO_4 . The isomeric 2,3-(HO) $_2$ deriv. gave a somewhat deeper color, whereas 2,3,4-(HO) $_3\text{C}_6\text{H}_2(\text{Me}_2\text{NC}_6\text{H}_4)_2\text{CH}$ in H_2SO_4 gave a rather distinct yellow color.

LOUIS E. WISE.

Attempted preparation of cyclic compounds analogous to the indazoles. E. NOELTING AND F. STEINLE. *Bull. soc. chim.* 17, 389-99(1915).—The article deals with a series of unsuccessful attempts to form compds. of the type $\text{R.O.CH}_2\text{N:N}$ or

R.O.CH.N.NH (where R = a phenylene radical containing 1 or more NO_2 or Br substituents) from substituted *o*-anisidines. The addition of 40 g. Br in 50 cc. AcOH to 20 g. of 2,4- $\text{H}_2\text{N}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{OMe}$ (A) in 100 cc. AcOH led to the formation, in nearly quant. yield, of 3,5-dibromo-4-dinitro-*o*-anisidine (B), 2,3,5,4- $\text{H}_2\text{NBr}_2(\text{O}_2\text{N})\text{C}_6\text{HOMe}$.

orange leaflets, m. 102°; acetyl derivative, yellow needles, m. 182°. Bromination of 5-nitro-*o*-anisidine (C) in AcOH, with subsequent treatment with aq. NaHSO_4 to decomp. the hydrobromide and to remove the excess of Br, yielded 3-bromo-5-nitro-*o*-anisidine (D), yellow, m. 140-1; acetyl derivative, needles, m. 204-5°, which in the presence of small amts. of KOH gives an intense yellow color. Ten g. of (A) in 15 cc. concd. H_2SO_4 and 100 cc. H_2O , when treated at 0° with 43 g. NaNO_2 in 20 cc. H_2O , the excess of HNO_2 being destroyed by urea, yielded a mixt. which showed typical diazo reactions and from which, on standing, was deposited a reddish brown

cryst. compd. (E), exploding 118°. (E) is apparently 4- $\text{O}_2\text{NC}_6\text{H}_3\text{O.N:N}$ or

$4\text{-O}_2\text{NC}_6\text{H}_4\text{O.N:N}$, previously obtained by Griess (ref. not given) from diazonitrophenol. The conversion of (E) into $2,4\text{-Cl(O}_2\text{N)C}_6\text{H}_3\text{OH}$, m. 110° , was effected by means of Cu_2Cl_2 in HCl . (E) coupled with $\beta\text{-6-C}_{10}\text{H}_6(\text{OH})\text{SO}_3\text{H}$ gives a reddish brown dyestuff, which is converted into a brownish black compd. on treatment with $\text{K}_2\text{Cr}_2\text{O}_7$. Attempted diazotization of (A) in glacial AcOH led only to the formation of *diazonitroanisolenitroanisidide* (F), $\text{R}'\text{N:N.NHR}'$ ($\text{R}' = 2,4\text{-MeO(O}_2\text{N)C}_6\text{H}_3$), microscopic yellow prisms, m. 205° (decompn.), forming readily hydrolyzed salts with alc. alkali. The weak basic properties of (B) rendered the diazotization difficult. The reaction was carried out in cold concd. H_2SO_4 or in glacial AcOH . In the latter case, the formation of a diazoamino compd. was not observed. The diazo solns. deposited the compound (I), orange needles, m. 189° , and exploding a few degrees above the m. p. The

diazotization of (C) proceeds smoothly in both H_2SO_4 and AcOH . The deriv of (C) in H_2SO_4 when treated with AcONa and 1 mol. PhNH_2 in aq. AcOH yielded *diazonitroanisoleanilide* (G), $2,5\text{-MeO(O}_2\text{N)C}_6\text{H}_3\text{N:N.NHPh}$, orange needles, m. 123° , forming readily hydrolyzed reddish brown salts with alc. alkali. When heated with a large excess of Ac_2O , (F) and (G) are decompd. with the quant. liberation of N. (D) formed a diazo deriv., stable in cold H_2SO_4 and AcOH . 4,5-Dinitro-*o*-anisidine, when diazotized in AcOH , readily yielded the compd. (II), previously prepd. by Meldola and Eyre (ref. not given), which when treated with Cu_2Cl_2 in HCl gave rise to $3,4,6\text{-O}_2\text{N-(HO)(MeO)C}_6\text{H}_2\text{Cl}$.

LOUIS E. WISE.

Aspirin. III. Anomalies of the decomposition of aspirin by water. D. E. TSAKALOTOS AND S. HORSCH. Univ. Athens. *Bull. soc. chim.* 17, 401-6(1915); cf. C. A. 9, 787, 2228.—Studies of the rate of decompn. of aspirin detd. by titrametric methods and by cond. measurements indicate that the reaction is exceedingly complex. The speed of reaction measured at 20° , 50° and 60° showed 2 minimum values. A similar anomaly was noted by Wijs (*Z. physik. Chem.* 12, 514 (1893)), in the rate of hydrolysis of AcOMe by H_2O . The anomalies of T. and H.'s reaction are probably due in part to the catalytic action of H and OH ions. Tabulated data are given.

LOUIS E. WISE.

***m*-Phenetidine and some of its derivatives. I.** FRÉDÉRIC REVERDIN AND J. LOKIETEK. Univ. Geneva. *Bull. soc. chim.* 17, 406-9(1915).—*m*-Phenetidine (A) was obtained in excellent yield by the following method: 150 g. of $3\text{-AcHNC}_6\text{H}_4\text{OH}$ with 48 g. NaOH in 400 cc. alc. were gradually treated under reflux with 150 g. of EtBr . The resulting product was hydrolyzed with HCl and (A) freed by means of aq. NaOH . The following derivs. of (A) were prepd.: *hydrochloride*, thin leaflets; *picrate*, yellow needles, m. 158° ; *formyl derivative*, grayish blue, m. 52° ; *benzoyl derivative*, needles, m. 103° ; *toluene-p-sulfonyl derivative*, pale yellow leaflets, m. 157° ; *toluene-o-nitro-p-sulfonyl derivative*, brilliant needles, m. 88° ; *1-ethoxy-2',4'-dinitro-3-diphenylamine*, $2,4\text{-(O}_2\text{N)}_2\text{-C}_6\text{H}_3\text{NHC}_6\text{H}_4\text{OEt}$, yellowish orange, m. 151° . The following azo dyestuffs were prepd. from the diazo deriv. of (A): *β -naphthol derivative*, red needles, m. 107° ; *sodium salt*, insol. in H_2O ; *salicylic acid derivative*, dyeing wool yellow; *resorcinol derivative*, dyeing wool brownish red; *naphthionic acid derivative*, dyeing wool reddish orange; and *naphthol-4-sulfonic acid derivative*, dyeing wool red.

LOUIS E. WISE.

Synthesis of mixed cycloglycylglycines formed by the action of glycerol on α -amino acid mixtures. L. C. MAILLARD. *Ann. chim.* 3, 225-52(1915).—A continuation of

M.'s previous work (cf. *C. A.* 9, 1911). The following cyclic dipeptides were prepd. by the usual methods: cyclo-*dl*-alanylglycine, $\text{CO.NH.CHMe.CO.NH.CH}_3$ (*A*) (purified by extn. of the crude product with abs. alc. to remove the less sol. cycloglycylglycine, evapn. of the ext. and re-extn. of the residue), fine needles, m. 229° (decompn.) (cor.). Fischer and Otto (*Ber.* 36, 2106 (1903)) give $244-5^\circ$, with partial preliminary decompn. Results of a detailed study of the m. p. of (*A*) seem to indicate that the crude product begins to turn brown at 230° , and m. about 260° . F. and O.'s samples were therefore probably impure. Cyclo-*dl*-leucylglycine, $\text{CO.NH.CH(C}_6\text{H}_5\text{).CO.NH.CH}_3$, bitter needles from alc., m. 227° (F. gives $244-5^\circ$). A mixt. of valine and leucine obtained by the HCl hydrolysis of horn, when treated in the usual manner, gave rise to cyclo-*dl*-leucylvaline, $\text{Me}_3\text{CHCH.CO.NH.CH(CH}_3\text{CHMe}_2\text{).CO.NH}$, silky needles, from alc., m. 260° . Literature relating to researches on the mixed dipeptides is critically reviewed.

LOUIS E. WISE.

Aromatic-aliphatic diazoamino compounds: Arylazodicyanodiamides. R. von WALTHER and W. GRIESHAMMER. Dresden. *J. prakt. Chem.* 92, 209-55 (1915).—*1-Phenyltriazeno-2-cyanoaminoiminomethane* (*a*), NCNHC(:NH)NHN:NPh , was prepd. by adding 44 g. NCNHC(:NH)NH_2 in H_2O to a cold diazotized soln. of $\text{PhNH}_2\cdot\text{HCl}$, then adding an excess of NaOH (the color changes from yellow to red), allowing to stand 0.5-1.0 min. and then acidifying with dil. HCl. By making the filtrate alk. and again acidifying and repeating the process 5-6 times, 70 g. of (*a*) was obtained, prisms from alc., decomp. 123° , easily sol. in alkalis and forms a yellow salt with $\text{C}_6\text{H}_5\text{N}$. With boiling H_2O it gives N, dicyanodiamide (*b*) and PhOH, stable toward NH_3 , H_2S and CS_2 . With HCHO, Ac_2O and BzCl it forms resinous products; *sodium salt*, yellow needles from alc.; *ammonium salt*, prisms from alc., partially dissociates in H_2O ; *silver salt*, yellow powder, explodes on heating; *lead salt*, yellow powder; *cobalt salt*, bluish red powder; *ferric and ferrous salts*. *2-Phenyl-2-methyltriazeno-1-cyanoaminoiminomethane*, $\text{NCNHC(:NH)N:NNMePh}$, prepd. by warming for 2 hrs. 2 g. of the above Na salt with 2 g. MeI in 100 cc. alc., and pptg. with H_2O , or better, by treating the Na salt with Me_2SO_4 , yellow needles from alc., decomp. $167-8^\circ$. *2-Phenyl-2-benzyl derivative*, $\text{NCNHC(:NH)N:NN(CH}_2\text{Ph)Ph}$, from the Na salt and ClCH_2Ph in $\text{C}_6\text{H}_5\text{N}$, fibrous needles from alc., decomp. $165-6^\circ$. *2-Phenyl-2-p-nitrobenzyl derivative*, similarly prepd. from *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Cl}$, needles from AcOEt, decomp. 162° . *1-p-Tolyltriazeno-2-cyanoaminoiminomethane*, $\text{NCNHC(:NH)NHN:NCC}_6\text{H}_4\text{Me}$, prepd. like (*a*) from $\text{H}_2\text{NC}_6\text{H}_4\text{Me}$, yellow rhombic crystals from alc., begin to decomp. 133° (darkening); *sodium salt*, yellow needles from alc. *2-p-Tolyl-2-methyl derivative*, $\text{NCNHC(:NH)N:NN(C}_6\text{H}_4\text{Me)Me}$, from the Na salt and Me_2SO_4 , yellow needles from alc. or 90% AcOH, decomp. $155-8^\circ$. On heating for 3 hrs. with 3% H_2SO_4 (until evolution of N ceased) it gave (*b*), $\text{H}_2\text{NC}_6\text{H}_4\text{Me}$ and a small amt. of $\text{HOC}_6\text{H}_4\text{Me}$, showing that in the methylation of the phenylazo compd., the Me group goes chiefly to the N atom of the aromatic amine, while at the same time a small amt. of the isomeric compd. is formed. *2-p-Tolyl-2-benzyl derivative*, from the Na salt and ClCH_2Ph , fibrous needles from alc., decomp. 163° ; *2-p-tolyl-2-p-nitrobenzyl derivative*, from *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{Cl}$, pale yellow needles, decomp. 158° ; warmed with BzH it decomps. into its components, giving (*b*), N and PhOH, stable toward SnCl_4 in acid, and toward H_2S and Zn in alkalis, and on warming with *p*- $\text{H}_2\text{NC}_6\text{H}_4\text{Me} + \text{H}_2\text{NPh.HCl}$, the usual rearrangement characteristic of diazonium salts into aminoazo deriva. does not take place, but a cleavage into its components. *1-o-Tolyl derivative*, $\text{NCNHC(:NH)NHN:NCC}_6\text{H}_4\text{Me}$, was prepd. similarly to the corresponding *p*-deriv. but purified by dissolving in dil. NaOH and pptg. with HCl, yellow needles from alc., decomp. 114° ; *sodium*

salt, yellow needles; *2-o-tolyl-2-methyl derivative*, $\text{NCNHC}(:\text{NH})\text{N}:\text{NNMeC}_6\text{H}_4\text{Me}$, from the Na salt and Me_2SO_4 , pale yellow leaves from C_6H_6 , decomp. 152° , more stable toward heat than the corresponding *p*-deriv.; *2-o-tolyl-2-benzyl derivative*, pale yellow needles, decomp. 160° ; *1-m-tolyl derivative*, yellow needles from alc., decomp. 115° ; *2-m-tolyl-2-methyl derivative*, yellow needles from alc., sinters 130° , decomp. 148° ; yield poor; *2-m-tolyl-2-benzyl derivative*, yellow lustrous needles and prisms from alc., decomp. 153° ; *1-p-chlorophenyl derivative* (c), from $\text{H}_2\text{NC}_6\text{H}_4\text{Cl}$, HCl , NaNO_2 and $\text{NCNHC}(:\text{NH})\text{NH}_2$, yellow rhombic crystals from alc., decomp. 140° (slow heating); it forms a salt with $\text{C}_6\text{H}_5\text{N}$, and is decompd. by H_2O , giving (b) and resinous products; *2-p-chlorophenyl-2-methyl derivative*, yellow needles, decomp. $160\text{--}70^\circ$; *2-p-chlorophenyl-2-benzyl derivative*, needles, decomp. $170\text{--}5^\circ$. Several attempts to obtain aminodicyanodiamide by reduction of (c) gave negative results as in the case of (a). *1-p-Bromophenyl derivative*, obtained similarly to (c), yellow rhombic crystals from alc., decomp. 160° ; it forms a yellow salt with $\text{C}_6\text{H}_5\text{N}$; *2-p-bromo-2-methyl derivative*, yellow needles, decomp. 185° ; *2-p-bromo-2-benzyl derivative*, fibrous needles, decomp. 186° . By diazotizing *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and treating with (b) *phenylazodicyanodiamide-o-carboxylic acid* (d), $\text{NCNHC}(:\text{NH})\text{NHN}:\text{NC}_6\text{H}_4\text{CO}_2\text{H}$, was obtained, yellow crystals from MeOH , decomp. 98° ; it is decompd. by boiling H_2O , yielding $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ and (b); *sodium salt*, from (d) and NaOEt , $\text{C}_{18}\text{H}_{13}\text{O}_4\text{N}_{12}\text{Na}_3$; *silver salt*, same compn. as the Na salt. An attempt to esterify the CN group in (c) with abs. alc. + HCl gave, instead of the ester, *p-chlorophenylguanyllurea hydrochloride*, $\text{ClC}_6\text{H}_4\text{NHC}(:\text{NH})\text{NHCO-NH}_2\cdot\text{HCl}$, prisms from alc., m. $172\text{--}3^\circ$. It can also be obtained by warming (c) with 14% HCl ; *chloroplatinate*, yellow crystals. The free base (e) was obtained by decompg. the HCl deriv. with NaOH , rhombic crystals from H_2O , m. 125° ; *silver salt*; *picrate*, m. 195° ; with Ac_2O it forms the *acetyl derivative*, prisms from AcOEt , m. $150\text{--}1^\circ$. The following analogous derivs. were similarly prepd.: *phenylguanyllurea*, prisms from H_2O , m. $62\text{--}3^\circ$; *picrate*, m. $181\text{--}2^\circ$; *hydrochloride*, prisms from H_2O , m. $174\text{--}5^\circ$; *p-tolyl derivative*, stellar leaves from H_2O , m. 143° ; *hydrochloride*, prisms from H_2O , m. $167\text{--}8^\circ$; *o-tolyl derivative*, octahedrons from H_2O , m. 136° ; *hydrochloride*, needles from H_2O , m. $73\text{--}4^\circ$; *m-tolyl derivative*, hexagonal leaves from H_2O , m. $97\text{--}8^\circ$; *hydrochloride*, prisms, m. $183\text{--}4^\circ$; *p-bromophenyl derivative*, prisms from 80% alc., m. 152° ; *hydrochloride*, leaves, sinter 165° , m. 170° . *Phenylguanyllurea-o-carboxylic acid*, $\text{HO}_2\text{CC}_6\text{H}_4\text{NHC}(:\text{NH})\text{NHCONH}_2$, prepd. by warming 10 g. of (d) in 50 cc. alc. with concd. HCl (yield, 3 g.), prisms and needles from AcOEt , sinter 250° ; decomp. $275\text{--}80^\circ$; *silver salt*. The constitution of the arylguanyllureas described was detd. by synthesizing, for comparison, phenylguanyllurea by evapg. a soln. of phenylcyanoguanidine in dil. HCl . The product formed was identical with that obtained by decompg. (a) with alc. + HCl . By suspending (a) in cold Et_2O and passing in HCl , the *hydrochloride* of the syn-form of (a) was obtained, m. 100° (decompn.). When warmed with H_2O it decompd., giving N , HCl and $\text{PhNHC}(:\text{NH})\text{NHCN}$. In the same way the following analogs were prepd.: *p-tolylcyanoguanidine*, leaves, m. $207\text{--}8^\circ$; *m-tolyl derivative*, leaves, m. $193\text{--}4^\circ$; *p-chlorophenyl derivative*, leaves, m. $197\text{--}8^\circ$; *p-bromophenyl derivative*, leaves, m. $196\text{--}7^\circ$. The labile HCl deriv. was obtained only in very small amts. *Phenylazodicyanodiamidine*, $\text{PhN}:\text{NNHC}(:\text{NH})\text{NHCONH}_2$, was obtained by diazotizing 22 g. dicyanodiamidine sulfate, 9.3 g. PhNH_2 , 7.2 g. NaNO_2 and 20 cc. concd. HCl , and making strongly alk., yellow needles from alc. + $\text{C}_6\text{H}_5\text{N}$, decomp. $176\text{--}7^\circ$. It has both acid and basic properties, and is decompd. by warm dil. acids, giving N ; *hydrochloride*, yellow prisms, decomp. 92° ; *picrate*, needles, begin to decomp. 70° . *Phenylazocycanoamide*, $\text{PhN}:\text{NNHCN}$, prepd. by adding 25 g. NCNHNa in H_2O , neutralized with HCl , to a mixt. of 31 g. PhNH_2 , 80 cc. concd. HCl and 24 g. NaNO_2 , decomp. 70° .

D. BREESE JONES.

Derivatives of *o*-aminophenol and α -amino- β -naphthol. F. VON MEYER. *J. prakt. Chem.* **92**, 255-71 (1915).—The main reactions described involve the formation of heterocyclic compds. which are derivs. of benzoxazole, $\text{C}_6\text{H}_4\text{N}:\text{C}(\text{OH})\text{O}$, and benz-

oxazolone, $\text{C}_6\text{H}_4\text{NH.CO.O}$. These formulas also represent the tautomeric forms of

carbonyl-*o*-aminophenol (*a*). Schmitt and Hentschel (cf. *J. prakt. Chem.* **37**, 28 (1888)) obtained (*a*) in 50% yield by shaking *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{OH}$ in C_6H_6 with COCl_2 in CHCl_3 , but by dissolving the former in $\text{C}_6\text{H}_5\text{N}$ and then adding COCl_2 and allowing the soln. to become warm, M. has obtained a better product in 82% yield, reddish needles, m. 137° . By interrupting the reaction and keeping the mixt. cool, a compd. was obtained whose properties and analysis agree with those of *o*-hydroxyphenylcarbamic acid, $\text{HO-C}_6\text{H}_4\text{-NHCO}_2\text{H}$, m. 95° ; on fusion or long standing it changes, with loss of H_2O , into (*a*). The following derivs. of (*a*) were prepd.: benzoyl derivative, $\text{C}_6\text{H}_4\text{.NBz.CO.O}$, from BzCl

in $\text{C}_6\text{H}_5\text{N}$ and (*a*), crystals, m. 165° ; ethoxy derivative, from (*a*) in NaOH and $\text{CO}(\text{OEt})_2$, leaves from alc., m. 78° ; phenylcarbamino derivative, by heating equimol. amts. of (*a*) and carbanil in C_6H_6 , short needles, m. 125° , nitro derivative, yellow needles from alc., m. 242° . Carbonyl- α -amino- β -naphthol (*b*) was prepd. similarly to (*a*) from $\alpha,\beta\text{-C}_{10}\text{H}_6(\text{NH}_2)\text{OH}$ in $\text{C}_6\text{H}_5\text{N}$ and COCl_2 , small, stout needles, by pptg. from alc. with H_2O , m. 206° ; with concd. H_2SO_4 at 150° it decomps. into CO_2 and $\text{H}_2\text{NC}_{10}\text{H}_6\text{OH}$. The following derivs. of (*b*) were prepd.: methyl derivative, from (*b*) in KOH and an excess of MeI , reddish needles from alc., m. 184° ; ethyl derivative, from EtI , fine needles, m. 141° ; acetyl derivative, by boiling (*b*) in Ac_2O containing a little AcONa , reddish needles, m. 121° ; benzoyl derivative, from BzCl in $\text{C}_6\text{H}_5\text{N}$, white needles by pptg. from alc. with H_2O , m. 256° ; phenylcarbamino- α -amino- β -naphthol, $1,2\text{-C}_{10}\text{H}_6(\text{OH})\text{NHCONHPh}$, obtained by heating (*b*) with PhNH_2 at 250° , needles from alc., m. 229° , easily sol. in alkalis, showing the presence of an OH group; by the action of Cl on (*b*) in cold AcOH , α -chlorocarbonylaminonaphthol was obtained, bluish crystals from alc., does not m. below 310° ; if the above reaction be conducted in CHCl_3 instead of AcOH , an isomeric β -chloro derivative is obtained, yellow crystals having a very high m. p.; prolonged action of Cl on (*b*) in hot AcOH yields dichloro- β -naphthoquinone, $\text{C}_{10}\text{H}_4\text{O}_2\text{Cl}_2$; dichloro derivative, by heating (*b*) with PCl_5 , reddish compd. with a very high m. p.; tetrachloroacetyl derivative, from Cl and (*b*) in AcOH , yellow cryst. powder, m. 75° , difficultly sol. in all org. solvents, and by heating with dil. NaOH loses 75% of its Cl ; monobromo derivative, from Br and (*b*) in AcOH at room temp., small yellow needles from alc., decomp. 250° ; dibromo derivative, by heating the components in AcOH , yellow needles m. above 300° ; mononitro derivative, from HNO_3 and (*b*) in AcOH , small yellow needles from alc., decomp. 270° ; NaNO_2 reacts with (*b*), forming a nitroso derivative, yellow crystals, decomp. 170° and m. 194° , gives a violet color with PhOH and H_2SO_4 , and on reduction with Zn dust and NH_4OH yields (*b*). In describing the following reactions M. uses the term " α -orthoform" for $2,3\text{-HO}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{Et}$ (*c*) and " β -orthoform" for $2,3\text{-H}_2\text{N}(\text{HO})\text{C}_6\text{H}_3\text{CO}_2\text{Et}$ (*d*). Derivs. of (*d*) possess stronger basic properties than those of (*c*). A mixt. of HCO_2H and (*c*) forms a thick liquid which on standing *in vacuo* over H_2SO_4 yields crystals of the α -orthoform formyl derivative, $2,3\text{-HO}(\text{HCONH})\text{C}_6\text{H}_3\text{CO}_2\text{Me}$, leaves from alc., m. 225° ; on heating to 240° it loses 1 H_2O , forming 4-carbomethoxybenzoxazole, $\text{MeO}_2\text{CC}_6\text{H}_3\text{N}:\text{CH.O}$, yellow needles

from C_6H_6 , m. 99° , b. $260\text{--}70^\circ$; (*d*) and HCO_2H react, forming a salt, m. $110\text{--}12^\circ$, which is decompd. by H_2O , giving (*d*), and on drying *in vacuo* over H_2SO_4 loses 1 H_2O , yielding the β -orthoform formyl derivative, also easily obtained by heating the components, lustrous needles from alc., m. 222° ; on distn. it forms 5-carbomethoxybenzoxazole

small needles from C_6H_6 , m. 107° ; with hot alc., the formyl deriv. is regenerated; AcOH readily forms a salt with (d), needles, m. 127° ; α -orthoform acetyl derivative, 1,2,4-AcNH-(HO) $C_6H_3CO_2Me$, prepd. from (c) and AcCl in C_6H_6 , white needles from MeOH, m. 188° ; heated with $ZnCl_2$ at 160° it yields 4-carbomethoxymethylbenzoxazole, fine needles, m. $103-4^\circ$; β -orthoform acetyl derivative, from (d) and AcCl in C_6H_5N , m. 204° ; heated with Ac_2O at $140-50^\circ$ it forms 5-carbomethoxymethylbenzoxazole, lustrous needles, m. 66° ; with boiling H_2O the Ac deriv. is regenerated. All of these acyl derivs. give with $FeCl_3$ deep colors, which are not formed with the benzoxazole derivs. A salt is formed from (c) and $(CO_2Et)_2$ (2 mols. (c) : 1 mol. $(CO_2Et)_2$), small needles, m. 112° ; heated for several hrs. with an excess of $(CO_2Et)_2$ it loses 2 mols. alc., giving oxalyl-bis- α -orthoform (I), short yellow prisms from C_6H_5N , m. $298-300^\circ$; ammonium

(I)

(II)

salt, $C_{18}H_{16}O_8N_2(NH_3)_2$, yellow powder; diacetyl derivative, from (I) and Ac_2O , stellar clusters of prisms from $C_6H_6 + AcOH$, m. 171° ; dibenzoyl derivative, from $BzCl$ in C_6H_5N , needles from C_6H_5N , m. 231° ; (d) and $(CO_2H)_2$ form a salt which on boiling with H_2O yields oxalyl-bis- β -orthoform, needles from C_6H_5N , m. $312-13^\circ$; phthalyl-bis- α -orthoform, prepd. from (c) and $(C_6H_4CO)_2O$, short prisms, m. 229° ; it does not give a color with $FeCl_3$, and is sol. in alkalis, and accordingly M. suggests for it the structure (II). 5-Carbomethoxythiolbenzoxazole, prepd. from $SO_2 + (d)$ in alc., needles, m. 228° . $COCl_2$ in PhMe reacts vigorously with (d) in dil. NaOH, forming 4-carbomethoxybenzoxazolone, leaves from alc., m. 228° ; with Me_2SO_4 it gives a methyl derivative, m. 168° , and with Ac_2O an acetyl derivative, leaves, m. 170° . Both (c) and (d) react with $NaNO_2$, forming the α - and β -diazooanhydrides, decomp., resp., 70° and 117° .

D. BRESE JONES.

Preparation of aliphatic aminohydrazines. A. DARAPSKY AND H. SPANNAGEL. Heidelberg. *J. prakt. Chem.* **92**, 272-96(1915).—Compds. having the character of both amines and hydrazines are known only in the aromatic series. This paper describes various attempts to prep. the analogous aliphatic compds. $HON:CMcAc$ (a) reacts with N_2H_4 in 2 ways: (1) with N_2H_4 salts in H_2O , giving the ketazine, $(HON:-CMcMe:N-)_2$ (b), and (2) with free N_2H_4 in alc., forming the oximehydrazone, $HON:-CMcMe:NNH_2$ (c). (b) was obtained in 83.3% yield from (a) in H_2O at 50° and $N_2H_4 \cdot H_2SO_4$, yellow powder, m. 229° (decompn.) (Forster and Dey give 230° ; *C. A.* **7**, 970); benzoyl derivative, from (b) in 6% KOH + $BzCl$, orange clusters from xylene, m. 215° . (c) (also described by F. and D.) was obtained in 67.8% yield, crystals, m. 138° , stable toward boiling alc. and concd. NaOH, but decompd. by mineral acids into (b) and N_2H_4 salts. o-Hydroxybenzaldiacetyloxime hydrazone, $HON:CMcMe:NN:-CHC_6H_4OH$, prepd. by boiling (c) with $HOCC_6H_4OH$ in alc., m. 168° , yellow needles from alc. $BzCl$ with (c) in 6% KOH gave a mixt. of the mono- and di-Bz derivs., while with PhNCS was obtained the thiosemicarbazone derivative, flesh-colored needles from alc., m. 201° ; yield, quant. Diacetyldihydrazone (d) was obtained by boiling (a) with $N_2H_4 \cdot H_2O$ for 8 hrs., short needles, m. 157° (previously prepd. and named "dimethylbishydrazinemethylene" by Curtius and Thun, *J. prakt. Chem.* **44**, 174(1891)), easily oxidized by HgO , evolving N and a gas having the odor of $MeC:CMc$. With dil. mineral acids (d) loses a mol. of N_2H_4 , forming dimethylazethane, yellow powder, m. above 260° , identical with that obtained by C. and T. With aldehydes (d) forms well-characterized condensation products; dibenzaldiacetyldihydrazone, from (d) and

BzH, fine, yellow needles from alc., m. 120° ; *di-o-hydroxybenzal derivative*, yellow fibrous needles from alc., m. 245° . Attempts to form an aminohydrazine by reduction of (c) were unsuccessful on account of the instability of the latter. In an analogous way its prepn. was tried from β -benzylmonooxime (e). Benzylloximehydrazone, prepd. by evapg. 2.3 g. (e) in 20 cc. alc. with 0.5 g. $N_2H_4 \cdot H_2O$, m. $167-8^{\circ}$, stout prisms from xylene; yield, 2 g. On reduction with Na-Hg in alc. it yields $(CHPhNH_2)_2$. Neither did $BzCH_2NH_2$ (f) lend itself to the formation of an aminohydrazine. The action of N_2H_4 on (f) leads to 3 different compds. according to the conditions of the expt.: (1) with HCl + $N_2H_4 \cdot H_2O$ in H_2O , (f) yields diphenyldihydropyrazine (cf. Gabriel, *Ber.* 41, 1133(1908)), red crystals, m. $167-8^{\circ}$; (2) N_2H_4Cl + (f) in dil. HCl, after neutralizing with NaOH, give $H_2NCBz : CPhCH_2NH_2$, yellow prisms, m. 130° ; (3) by boiling (f)-HCl with an excess of $N_2H_4 \cdot H_2O$ for 1 hr., *aminoacetophenoneazine*, $(H_2NCH_2CPh : N-)_2$, is formed, needles from alc., m. 157° . $MeCHBrCH_2NH_2$ with N_2H_4 + HBr did not give the expected hydrazinoamine, but lost 1 mol. HBr, forming a thick, basic oil which gave no cryst. deriv. for its identification. Diphenylhydroxyethylamine (cf. Polonowska, *Ber.* 20, 492(1887)) gives directly with PCl_5 $(PhCHCl)_2$, but by shaking a suspension of the former in freshly distd. $AcCl$ + an excess of PCl_5 , *diphenylchloroethylamine hydrochloride* (g), $PhCHClCHPhNH_2 \cdot HCl$, is obtained, cryst. powder, m. 233° (decompn.); free base, oil; *chloroplatinate*, deep yellow needles, m. 204° ; *nitrate*, large tablets from H_2O , m. 185° ; *benzoyl derivative*, m. 195° . By boiling 2.7 g. of (g) with 3 mols. anhydrous N_2H_4 , 1.9 g. of an oil was obtained which crystd. on cooling,

and was identified as *diphenylethyleneimine*, $PhCH.NH.CHPh$, long needles, m. 83° ; *chloroplatinate*, long needles, m. 204° . $BzNHN : CHPh$ was obtained by shaking with BzH the oily product formed by boiling $BzNH(CH_2)_2Cl$ with dry N_2H_4 , needles, m. 204° .
D. BRESEE JONES.

Action of hydrazoic acid on quinone. E. OLIVERI-MANDALÀ AND E. CALDERARO. *Gazz. chim. ital.* 45, I, 307-13(1915).—In the following expts. the study of the condensation and addition reactions that O.-M. has been making with HN_3 on unsatd. compds. is continued. From benzoquinone + HN_3 a compd. composed of 1 mol. of each, which behaves like an azide, was obtained. This result shows that HN_3 does not combine simultaneously through 2 N atoms but that it is united through 1 N atom, which is in harmony with the results previously obtained with the ketenes and with the esters of iso- and thiocyanic acids. The action of HN_3 on *p*-quinone in C_6H_6 gives, according to the conditions of the expt., quinhydrone and an azide (probably (I)).

The mechanism of this addition may be explained either by the theory of partial valences or by the addition at the ethylene bond. The results do not agree with those of Escales (*Chem. Ztg.* 29, 31(1905)) who, having obtained a dark violet compd. free from N, concluded that HN_3 does not react on quinone like HCl. O.-M. and C. found that the compd. free from N is quinhydrone and that the azide was not found by E. because his solns. were too dil. If HN_3 in C_6H_6 is added to quinone in C_6H_6 , the mixt. becomes orange-yellow and then dark red and finally deposits quinhydrone in gray-green crystals with a metallic reflex, m. $167-90^{\circ}$. The quinhydrone may be formed thus: (1) 1 quinone + 2 $HN_3 \longrightarrow$ 1 quinol + 3 N_2 ; (2) 1 quinol + 1 quinone $\rightleftharpoons$

quinhydrone. The fact that on further addition of HN_3 the quinhydrone dissolves and ppts. (I) slowly, makes it possible that the addition of HN_3 to quinone proceeds in the same way as for HCl . Thus HCl acting on quinone first gives quinhydrone, which then dissolves and gives chloroquinol. Of the numerous explanations of this reaction O.-M. and C. prefer that of Schmidlin (*C. A.* 5, 3252), according to which the chloroquinol that is formed through direct addition of the HCl to the quinone gives finally chloroquinone and quinol. The equil. arising between quinone, chloroquinone, quinol and chloroquinol is destroyed by the formation of insol. quinhydrone. The HCl reacts further on the quinhydrone to give chloroquinol and quinol, and the quinol finally is oxidized to quinone and reduces the chloroquinone to chloroquinol. This explanation may be applied to the action of quinone on HN_3 as follows: (1) quinone + $\text{HN}_3 \rightleftharpoons$ (I); (2) (I) + quinone $\rightleftharpoons$ $\text{O}:\text{C}_6\text{H}_4\text{N}_3:\text{O}$ (corresponding to (I)) + quinol; (3) quinone + quinol $\rightleftharpoons$ quinhydrone; (4) quinhydrone + $\text{HN}_3 \rightleftharpoons$ quinol + (I); (5) quinol + $\text{O}:\text{C}_6\text{H}_4\text{N}_3:\text{O} \rightleftharpoons$ quinone + (I). In all these reactions is assumed the temporary formation of the azide (II), which is reduced to (I). But owing to the facility with which the N_3 isomerizes itself the existence of (II) is possible only when the velocity of transformation into the triazole compd. (III) is small with respect to the velocity of reaction (5). 50 g. NaN_3 in a fractional distg. flask in a boiling H_2O bath treated dropwise with dil. H_2SO_4 (1:1) evolved HN_3 which was passed through a good condenser, the inner tube of which contained CaCl_2 , and collected in 50 cc. C_6H_6 . This soln., dried with Na_2SO_4 , was poured into a concd. soln. of 5 g. quinone in C_6H_6 . The gray-green compd. first pptd. decomps. $\approx 100^\circ$, with slow heating 130° . The N content is low, which indicates that the compd. is mixed with quinone or quinhydrone or a mol. compd., $\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\text{O}_2\cdot\text{HN}_3$, of C_6H_6 , HN_3 and quinone. The last seems more probable since in solvents it seps. into quinone and HN_3 , while (I) decomps. to give N_2 . That this addition compd. ($\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\text{O}_2\cdot\text{HN}_3$) is formed is rendered probable by the work of Meyer (*C. A.* 2, 3078), who found that quinone forms colored unstable addition compds. with acids and metallic chlorides containing C_6H_5 of crystn. Using more concd. solns. of HN_3 quinhydrone seps. as was stated above and redissolves in C_6H_6 with the evolution of heat and ppts. *triazosquinol* (I) as pearl-white leaves, quite sensitive to light, sol. in dil. alkalis; its properties exclude the other possible or quinonic formula. (I) is highly explosive. It is sol. in NH_4OH with a green color that changes to red, evolving N_2 . With acids and alkalis it undergoes this decompn. in the cold. Shaken with quinone in C_6H_6 it gives quinhydrone without the evolution of N_2 .

E. J. WITZEMANN.

The isomerism of erucic, brassidinic and isoerucic acids. II. L. MASCARELLI AND B. TOSCHI. Univ. Bologna. *Gazz. chim. ital.* 45, I, 313-9(1915); cf. *C. A.* 9, 1761.—The cryoscopic behavior of the above 3 acids when dissolved in the corresponding satd. acid, behenic acid, is discussed in this paper. Of the 3 acids only 1 (erucic acid) is cryoscopically normal in behenic acid; the other 2 show higher mol. wts. Thus 2 of the acids may have a similar configuration (if the double bond is in the same position in all 3 of the acids) and the other a different one. If Bruni is correct that the unsatd. compds. form a solid soln. with a relatively satd. compd., i. e., of the *trans* type, erucic acid belongs to the *cis* and the other 2 compds. to the *trans* type. These conclusions with regard to the configuration of erucic acid and brassidinic acid are in accord with the physical properties of the 2 acids and with what was pointed out by Bruni, according to whom the unsatd. acid (brassidinic) when dissolved in the solid state in the corresponding satd. acid (behenic acid) has a higher m. p., is less sol., and is more stable than the isomeric erucic acid which does not give mixed crystals, all of which is in accordance with Michael's (*J. prakt. Chem.* [2] 52, 345(1895)) stability rule which says that the malenoid form of ethylenic compds. m. lower, are more sol. and

more volatile than the fumaroid form. The f. p. const. for behenic acid, which had not been previously used for mol. wt. detns., was detd. The com. erucic acid contains arachic acid which was removed by dissolving 100 g. in 400 cc. warm glacial AcOH, when crystals of arachic acid sepd. in 2 or 3 days and were filtered off *in vacuo* and the erucic acid recrystd. from EtOH in a CO₂ atm.; pearly scales, m. 33-4°. The brassidinic acid was obtained by Reimer and Will's method (*Ber.* 19, 3321 (1886)) and crystd. from EtOH in a CO₂ atm. as white scales, m. 59-60°. Erucic acid treated with PI₃ was transformed into iodobehenic acid (Ponzio, *Gazz. chim. ital.* 1904, II, 52) and this boiled with KOH-EtOH to remove HI; the isoerucic acid m. 52-3°. The behenic acid was obtained by reducing erucic acid in EtOH (Skita, *C. A.* 7, 2558) with colloidal Pt and 2 atm. pressure of H₂. The muddy brown liquid was poured into H₂O and sepd. white behenic acid, shining scales, m. 82-3°, b₁₅ 262-5°; the last trace of Pt was removed by distg. and that of erucic acid by washing with EtOH. The f. p. const. of behenic acid, detd. in C₁₀H₈, (PhCH₂)₂, BzOH, *p*-Br₂C₆H₄, oleic acid and elaidinic acid, gave an av. value of 44.4. The value calcd. according to Raoult's rule is 210.8. The heat of fusion of behenic acid according to van't Hoff's formula is 19.0 cal. per g. mol. The cryoscopic behavior of erucic in behenic acid was next detd. The mol. wt. was found to be normal. Thus one cannot speak of the soly. in the solid state of erucic acid in the corresponding satd. acid and according to what was stated in the previous paper the *cis* form is the probable constitution of erucic acid. The mol. wt. of brassidinic acid in behenic acid is slightly above normal so that there is a certain soly. in the solid state of brassidinic and behenic acids which makes the *trans* configuration probable for brassidinic acid. The mol. wt. of isoerucic acid in behenic acid gives high values that indicate the formation of a solid soln. and speaks for the *trans* configuration for isoerucic acid.

E. J. WITZEMANN.

Aromatic nitro derivatives. III. Dinitromethoxybenzoic and dinitroaminobenzoic acids. MICHELE GIUA. Milan. *Gazz. chim. ital.* 45, I, 352-8 (1915).—In order to complete exptl. results on 2,3,4- (a) and 3,4,6-(O₂N)₂C₆H₂CO₂H (b) (*C. A.* 9, 1479, 2089) the behavior of these compds. with KOMe and EtOH-NH₃ was studied. KOH (2 mols.) reacts in MeOH to give 3,2,4- (c) and 3,4,6-MeO(O₂N)₂-C₆H₂CO₂H (d) and EtOH-NH₃ at room temp. gives 3,2,4- (e) and 3,4,6-H₂N(O₂N)₂-CH₂CO₂H (f) exactly as β- and γ-C₆H₂(NO₂)₃Me give H₂NC₆H₂(NO₂)₂Me with NH₃ in Me₂CO. The behavior of these acids is in accord with the rule on the reactivity of the NO₂ group in the C₆H₄ ring developed by Körner and Laubenheimer. This facility of reaction is explained by the adjacency of the 2 NO₂ groups ("loosening" action of 1 group on the other) and not by the influence of the CO₂H, as is indicated by the case of 3,4,5-(O₂N)₃C₆H₂CO₂H, which replaces NO₂ with OH in boiling H₂O (Körner and Contardi, *C. A.* 9, 1478). The weakening influence of the NO₂ is exercised on other groups also; thus Körner (*Gazz. chim. ital.* 1874, 305) converted Cl(O₂N)₂C₆H₃OMe into Cl(O₂N)₂C₆H₃NH₂ with NH₃. Laubenheimer (*Ber.* 9, 760, 766, 1826 (1876); 11, 1155, 1448 (1878)) found that KOH, EtOH-NH₃ and PhNH₂, resp., give with (O₂N)₂C₆H₃Cl Cl(O₂N)₂C₆H₃OH, Cl(O₂N)₂C₆H₃NH₂ and Cl(O₂N)₂C₆H₃NHPh. Such cases of substitution are too numerous to require further comment. Both (a) and (b) heated a little above their m. p. evolve CO₂. Of the 2 (b) is more stable. Attempts to eliminate CO₂ from about 1 g. (a) fused in a distg. flask under 15 mm. gave a violent explosion after 5 or 6 mins. Attempts were made to eliminate CO₂ by long boiling with H₂O acidulated with HCl (this gave good results with *sym*-C₆H₂(NO₂)₂CO₂H); on cooling much unchanged (a) sepd. and a small quantity of an oily compd. that solidifies at once and m. 105-6° was obtained: since 1,2,3-C₆H₃(NO₂)₃ made by Körner and Contardi (*C. A.* 9, 1478), m. 127°, was the only compd. sought. β-Trinitrotoluene or (a) heated with concd. HNO₃ for 3 or 4 days gave (a).

but it was decompd. 0.4 g. (b) mixed with 0.6 g. MgO and kept at 200° 10 mins. was extd. with EtOH after cooling and sepd. reddish lamellas of *asym*-C₆H₅(NO₂)₂, m. 61–2°. Prolonged boiling of (b) with HCl-H₂O failed to give appreciable amts. of this compd. 5 g. (a) in 30 cc. MeOH treated with 10 cc. of 20% KOH seps. in about 15 mins. yellowish needles of the salt of 2,4-dinitro-3-methoxybenzoic acid (c). Thrown into dil. HCl, white needles of the free acid, browns 235°, m. 240–1°, seps.; it gives no color with cold alkali, and a bright yellow color when heated; 10% AgNO₃ ppts. the silver salt in small white cubes from the aq. soln. of (c). (b) treated as above gives the K salt of 4,6-dinitromethoxybenzoic acid, yellow shining lamellas; the free acid seps. as white needles, m. 186–7°, gives a yellow color with hot alkali. 10 g. (b) in 40 cc. EtOH satd. with dry NH₃ sepd. quant. a yellow NH₄ salt of 3,6-dinitro-3-aminobenzoic acid, which, treated in H₂O with HCl, sepd. the free acid, yellow needles, m. 270° (decompn.); with alkali it gives an intense wine red color; the silver salt, obtained as usual, crystd. in golden yellow needles with 1 H₂O; the anhydrous salt seps. from concd. solns.; the MeOH soln. of (d) ppts. the potassium salt on the addition of 22% KOH as a bright yellow powder. 5 g. (a) in 25 cc. EtOH satd. with dry NH₃ pptd. the yellow NH₄ salt of 2,4-dinitro-3-aminobenzoic acid, m. 240° (decompn.). Further results will be described later.

E. J. WITZEMANN.

Spontaneous oxidation in the presence of aldehydes. The transformation of benzalphenylisoxazolone into diphenylisoxazolecarboxylic acid. MARIO BETTI. *Gazz. chim. ital.* 45, I, 362–71 (1915).—It was shown (C. A. 1, 857; 2, 3343) previously that benzalmethylphenylpyrazolone in NH₃ in the presence of atm. O₂ gives rubazonic acid by spontaneous oxidation. This oxidation is favored by the BzH which is detached from the pyrazolone and acts as a catalyzer. The analogy of the above to the oxazolone compds. induced B. to try this reaction with benzalphenylisoxazolone (a), PhC:N.O.CO.C:CHPh. The reaction in this case proceeds quite differently from the

preceding and it is necessary to add BzH if a good yield is desired. The product is colorless and has a neutral reaction and its compn. corresponds to (I) which contains the

rubazonic acid group. But this formula does not conform to the chem. properties, which conform with (II). (II) may be formed by oxidation of an amide derivable from (a) thus: HO.N:CPh.C(CONH₂):CHPh + O → (II). The correctness of (II) was confirmed by transforming the compd. into the free acid *diphenylisoxazolecarboxylic acid* (b), which by the elimination of CO₂ gave diphenylisoxazole, previously prepd. by Goldschmidt (*Ber.* 28, 2540 (1895)) by the action of α,β-dichlorobenzalacetophenone. Not wishing to base the structure of (b) on a pyrogenic reaction a synthesis analogous to that used by Claisen (*Ann.* 277, 173 (1893)) in the prepn. of dimethylisoxazolecarboxylic acid was carried out. Thus NH₂OH treated with Bz₂CHCO₂Et and sapond. gave a product identical with (b). This new synthesis of a deriv. of isoxazole is a fine example of the formation of a heterocyclic nucleus as the result of spontaneous oxidation in the presence of BzH and NH₃. 20 g. phenylisoxazolone prepd. by the action of NH₂OH.HCl on Bz₂CHCO₂Et in 200 cc. hot EtOH treated with a small excess of BzH soln. gave a citron-yellow soln. which was boiled a few mins. On cooling (a) sepd. as bright yellow pearly crystals, m. 190–1°. It was dissolved in a little cold NH₃-EtOH, and treated with a little BzH and boiled on the H₂O bath 1 hr. The orange-red liquid was concd. to a small vol., cooled with H₂O and again made slightly alk. with NH₃, when it deposited *diphenylisoxazole*-

carboxylic amide (II), nearly rose-colored shining leaves or massive rose prisms, m. 229–30° (browns), insol. in cold alkalis, but on heating dissolves with the evolution of NH_3 . The EtOH mother liquors give on concg. rose crystals that at 160–180° undergo a change and finally m. 229–30°, dissolves with the loss of NH_3 in alkalis. The compd. was not identified owing to the lack of material. 4 g. of (II) heated with rather concd. NaOH dissolved and evolved NH_3 . The filtered liquid sepd. the sodium salt of (b) as pearly scales. The aq. soln. acidified with HCl ppts. the free acid (b) as cryst. flocks, which sep. as white cubes or rhombohedra from boiling H_2O -EtOH, m. 233°. A small amt. of a 2nd product, rose needles, m. 153°, was sepd. from the mother liquors. The above Na salt purified by recrystn. and treated with AgNO_3 gave a white flocculent ppt., nearly insol. in boiling H_2O but sol. in NH_3 ; with BaCl_2 it gave a white powdery ppt. sol. in hot H_2O and repptg. on cooling; CuSO_4 gave a S-yellow ppt. that dissolves on boiling and apparently undergoes some change; HgCl_2 causes a faint whitening; $\text{Pb}(\text{OAc})_2$ gives a flocculent ppt., sol. in hot H_2O and sepg. on cooling; FeCl_3 gives a silver-colored ppt. even in dil. soln. which is not changed by boiling. Although the CO_2H acids of other N-rings are decompd. by superheating quite neatly into CO_2 and decarboxylated deriv. (b) when treated in this way undergoes a profound decompn. and gives only a little diphenylisoxazole. 0.5 g. (b) heated slowly in a small distg. flask began to lose CO_2 above 233° (the m. p.) and formed yellow vapors which recondensed to an oily liquid and solidified as a brown mass. Dissolved in EtOH, some brown crystals, m. 140–1°, were sepd. In the synthesis of (b) from $\text{Bz}_2\text{CHCO}_2\text{Et}$ the latter was prepd. at first by the method found in the literature (Ber. 16, 2133(1883)). Later it was prepd. thus: $\text{BzCH}_2\text{CO}_2\text{Et}$ was emulsified in dil. NaOH and treated gradually with BzCl with energetic shaking. When the soln. becomes only slightly alk. or neutral the whole solid mass is filtered, washed with H_2O , pressed and the $\text{Bz}_2\text{CHCO}_2\text{Et}$ crystd. from EtOH as white rosetts, m. 110°. 12 g. $\text{Bz}_2\text{CHCO}_2\text{Et}$ warmed until dissolved with 110 g. AcOH were treated with the mol. amt. of $\text{NH}_2\text{OH}\cdot\text{HCl}$ and NaOAc in 5 cc. hot H_2O . The mixt. was agitated and heated at 60° for a few hrs. and poured after 12 hrs. into H_2O containing ice which pptd. a yellow semi-cryst. mixt. of diphenylisoxazolecarboxylic ester (c) and phenylisoxazolone. Grinding the mixt. with hot. dil. aq. alc. gave brilliant prisms of (c), m. 51–2°. 4.50 g. (c) boiled 0.5 hr. under a condenser with dil. NaOH gave a yellow soln. from which the salt sepd. on cooling. The soln. of the Na salt gave with dil. HCl a pale rose ppt. identical with (b), m. 233°. The Na salt was similar and gave all of the reactions described above. Derivatives of benzalmethylisoxazolone. MARIO BETTI AND LUIGI ALESSANDRI. *Ibid* 462–9.—Benzalmethylisoxazolone (III) in NH_2EtOH containing BzH undergoes an oxidation analogous to that above, giving the α -phenyl- γ -methylisoxazolecarboxylic amide (IV) which was then converted into the

free acid (V) and α -phenyl- γ -methylisoxazole (VI) successively. (VI) has been obtained by Goldschmidt (Ber. 28, 1532(1895)) by means of chlorobenzalacetoxime and by Moureu and Brachin (Compt. rend. 137, 795(1903)) by the action of NH_2OH on $\text{AcC}::\text{CPh}$. B. and A. also attempted to prep. (V) by the action of NH_2OH on $\text{BzCHAcCO}_2\text{Et}$ but obtained an isomer (m. 189°) which is probably α -methyl- γ -phenylisoxazolecarboxylic acid (VII), since by loss of CO_2 it gives (VI). The relationship of (V) and (VII) will be further discussed in subsequent papers. To (III) in a little NH_2EtOH BzH was added and the mixt. heated 0.5 hr. under a condenser on the H_2O bath; the cool mixt. was again made strongly alk. with NH_3 and after 24 hrs. minute rose-colored

leaves of (IV) were filtered off, m. 250° (decompn.). By evapg. the filtrate additional crops were obtained. (IV) is sol. in hot H_2O or hot $EtOH$ from which it seps. as rose needles, m. $256-7^{\circ}$ (brown liquid). 4 g. (IV) boiled with dil. $NaOH$ evolves NH_3 , becomes yellow, and on acidifying with dil. HCl gives rose or straw-yellow coarse crystals of (V); it crysts. from H_2O as nearly colorless rhombohedra, m. 157° , decomp. 220° ; *calcium salt*, $C_{11}H_8O_2N_2Ca \cdot 3H_2O$, brilliant prisms. 3 g. (V) heated carefully with a direct flame in a distg. flask decomp. with the formation of tar and a viscous brown oil. that solidifies on cooling. This, ground up with H_2O , made alk. with $NaOH$ and distd. with steam, gave a colorless oil which forms pearly crystals of (VI) having an aromatic odor, m. $67-8^{\circ}$, b. $265-70^{\circ}$. A better result is obtained by boiling (V) for 2 hrs. under a condenser with concd. HCl ; the cold liquid filtered, treated with $NaOH$, etc., gives (VI). $BzCHAcCO_2Et$ (Claisen, *Ann.* 291, 68(1896)) in glacial $AcOH$ was treated with the mol. amt. of $NH_4OH \cdot HCl$ and $NaOAc$ in the minimum amt. of H_2O ; the mixt. was agitated and heated for $\frac{1}{4}$ hr. on the H_2O bath, cooled and poured into much ice H_2O , which sepd. a yellow ppt. of *ethyl phenylmethylisoxazole-carboxylate* (d), $C_{12}H_{14}O_2N$, recrystd. from $EtOH$, m. $52-3^{\circ}$; 5 g. (d) heated with dil. $NaOH$ gave on adding dil. HCl a ppt. of *phenylmethylisoxazolecarboxylic acid*, prisms from $EtOH$, m. 189° , which, heated in the distg. flask, gave finally *phenylmethylisoxazole* in pearly crystals, m. $67-8^{\circ}$, identical with (VI). E. J. WITZEMANN.

The esters of silicic acid. GIOVANNI PELLINI. Univ. Palermo. *Gazz. chim. ital.* 45, I, 380-5(1915).—The chem. individuality of a number of hydrates derivable from SiO_2 has not been established with certainty. Knowledge of the constitution of silicic acids has been gained by a study of their organic esters; thus silicon halides react with alcs. and phenols to give tetra-alkyl silicates: $4ROH + SiX_4 \longrightarrow Si(OR)_4 + 4HX$. The hexa-Me and hexa-Et esters of $H_6Si_2O_7$ are known. The di-Et deriv. of H_2SiO_2 was obtained by Ebelman (*Ann.* 57, 331(1846)) but could not be obtained by Friedel and Crafts (*Ann.* 136, 210(1865)); a polymer $(Et_2SiO_2)_n$ was obtained by Troost and Hautefeuille (*Ann. chim.* [5] 7, 472). Thus our knowledge of the esters of the polysilicic acids is very limited. The purpose of these expts. was to prep. some organic polysilicates in order to contribute to the constitution of polysilicic acids and natural silicates. P. prepd. the chlorosilicic acid esters by the action of $SiCl_4$ on the normal esters and these react in abs. Et_2O with Ag_2O thus: (1) $2Si(OR)_2Cl + Ag_2O \longrightarrow Si_2O(OR)_4 + 2AgCl$; (2) $Si(OR)_2Cl_2 + Ag_2O \longrightarrow SiO(OR)_2 + 2AgCl$; (3) $2Si(OR)_3Cl + 3Ag_2O \longrightarrow Si_2O_3(OR)_6 + 6AgCl$. The esters of $H_6Si_2O_7$, H_2SiO_2 and $H_4Si_2O_5$ were obtained. Treating Et_2SiO_2 with $SiCl_4$ in known amts. at high temps. in the sealed tube gave a mixt. of 3 chlorohydrins which on fractional distn. gave no const. boiling fractions; the b. p. rose gradually while distg. Fractions collected at the b. ps. given by Friedel and Craft (*Ann. chim.* [4] 9, 5(1866)) and heated in abs. Et_2O on the H_2O bath with excess of Ag_2O containing only a trace of H_2O (cf. Madsen, *C. A.* 7, 3120) gave, after removing $AgCl$ and evapn., liquid products. $(EtO)_2SiCl_2$ treated in this way gave the *ethyl diorthosilicate*; no other product of const. compn. was isolated from the treatment of the other Cl derivs. Better success was had with the derivs. of *l*-borneol. This treated with the proper mol. amt. of $SiCl_4$ gives rise to 4 compds., $(C_{10}H_{17}O)_2Si$ (a), $(C_{10}H_{17}O)_3SiCl$ (b), $(C_{10}H_{17}O)_2SiCl_2$ (c), and $(C_{10}H_{17}O)SiCl_3$ (d). All are quite stable; the 1st is difficultly sapond. by boiling $EtOH \cdot KOH$; the last is sapond., by H_2O ; *l*-borneol is recovered from the products of sapon. The $(C_{10}H_{17}O)SiCl_3$ treated with Ag_2O gave $(C_{10}H_{17})_2Si_2O_5$ corresponding to $H_2Si_2O_5$. Recently Morey (cf. *C. A.* 8, 1248) prepd. $K_2Si_2O_5$, $KHSi_2O_5$ and $Na_2Si_2O_5$. The mineral rivaite, $(Ca, Na_2)_2Si_2O_5$ (Zambonini, *C. A.* 9, 774), is a salt of $H_2Si_2O_5$. Okenite, apofillite, petalite and milarite are less certainly derived from it. 1 mol. of $SiCl_4$ in petr. ether treated gradually with 4 mols. *l*-borneol and heated on the H_2O bath as long as HCl is evolved, then evapd.,

redissolved in petr. ether + an equal vol. of EtOH sepd. on spontaneous evapn. *tetra-l-bornyl silicate* (a), crystals, m. 291–2°, sol. in ligroin, C₆H₆ and PhMe. 1 mol. SiCl₄ similarly treated with 3 mols. *l*-borneol gives on distg. in *vacuo* *tri-l-bornyl monochlorosilicate* (b), b_{7–8} 260–90°, crystals, m. 215–8°. *Di-l-bornyl dichlorosilicate* (c) was obtained similarly as a dense colorless liquid. b₁₀ 203–5°, gives white crystals below 20°. *Mono-l-bornyl trichlorosilicate* (d) is a liquid which b₇₀₀ 140–2°. The optical rotations (the 1st 2 in PhMe) are as follows: (a) $[\alpha]_D^{24.9^\circ} -20.09^\circ$, (d) $[\alpha]_D^{20^\circ} -42.88^\circ$; liquid (c) $[\alpha]_D^{25.4^\circ} -36.72^\circ$; liquid (b) $[\alpha]_D^{24.9^\circ} -20.09^\circ$. (b) in Et₂O heated for a long time with excess of Ag₂O gives glassy scales of *l-bornyl dimetasilicates*, (C₁₀H₁₇O)₂Si₂O₃, softens about 92°, liquefies $\pm 135-40^\circ$, sol. in org. solvents. The expts. are to be continued.

E. J. WITZEMANN.

Derivatives of diaminoguanidine. AUGUSTO GAITER. Univ. Genoa. *Gass. chim. ital.* 45, I, 450–61 (1915).—By the action of BrCN on NH₂NH₂, Pellizzari and Cantone (*Idem* 35, I, 291) obtained HN:C(NHNH₂)₂.HBr and P. and Gaiter (*C. A.* 9, 450) improved the method. The unsym. or hydrazone formula H₂NN:C(NH₂)NHNH₂ for diaminoguanidine (a) is also possible. If the >NNH₂ group can exist in triaminoguanidine (cf. *C. A.* 9, 450) it may also exist in (a). Thiele gave it the imide formula while Ponzio and Gastaldi (*C. A.* 8, 80) admitted that in the formation of diaminotetrazine it reacts in the hydrazone form. G. found that BzCl reacting with (a) gives a di-Bz deriv. and tetrabenzoyldiaminoguanidine which on hydrolysis gives 2 mols. of *sym*-dibenzoylhydrazide thus: HN:C(NHNH₂)₂ → HN:C(NBzNHBz)₂ which with 2H₂O → 2(NHBz)₂ + CO₂ + NH₃. Moreover there is a strict analogy between (a) and aminoguanidine since both give addition products with aliphatic and aromatic aldehydes, HN:C(NHNH₂)₂ + 2RCHO → 2H₂O + HN:C(NHN:CHR)₂, which are described below. Although free (a) cannot be obtained on account of its great soly. and instability these condensation products are easily sepd. as well as crystd. compds. The product obtained with glyoxal is the result of the action of 1 mol. with (a) and is probably a heptagonal ring depending on whether it reacts in the usual or in the desmotropic form. The action of the fatty acids on (a) was also studied; in this the components react in monomol. quantities, probably giving HN:C(NHNH₂)NHNHCHO (in the case of HCO₂H) which then loses H₂O to give HN:C.NH.N:CH.NH.NH (b) or HN:C.NH.N:CH.NNH₂ (c). Since this deriv.

gives a condensation product with BzH which contains an NH₂ group and since with HNO₂ it gives a NO deriv. identical with aminotriazole (Thiele and Manchot, *Ann.* 303, 45 (1898)), G. considers its formula to be (c). But (c) may exist as the tautomer H₂N.N:CH:N.N:CNH₂ (d). Although T. and M. prefer formula (c) G. prefers (d),

since it does not react with 2 mols. of BzH as (c) should be able to do. This base (c) or (d), which is called *N-aminoiminodihydrotriazole*, is intermediate between HC:N.N:CH.NNH₂ (*Ber.* 39, 2619, 3372, 4106), and HN:C.NH.NH.C:(NH.NNH₂)

(*Gass. chim. ital.* 37, II, 317). One mol. diaminoguanidine-HBr (e) + 2 mols. *o*-HO-C₆H₄CHO in H₂O reacting in the presence of a few drops of HBr gave a cheesy ppt. of *salicylidenediaminoguanidine hydrobromide*, HN:C(NHN:CHC₆H₄OH)₂.HBr, m. 240°; treated in H₂O with Na₂CO₃ the *salicylidenediaminoguanidine*, C₁₄H₁₁O₂N₄, seps. in shining yellow scales from EtOH, m. 201–3°. 1 mol. (e) treated in EtOH with the calcd. amt. of *m*-O₂NC₆H₄CHO gave a yellow powdery ppt., which gradually reddens in the light, of *m-nitrobenzylidenediaminoguanidine hydrobromide* (f), HN:C(NHN:CHC₆H₄NO₂)₂.HBr, little sol. in EtOH, insol. in other common solvents, m. 292° (decompn.). (f) boiled in NH₄OH gave minute yellow crystals of *m-nitrobenzylidenediaminoguanidine*, C₁₄H₁₁H₇O₄, m. 240–2°. 2 g. (e) in 20 cc. H₂O + 1.7 g. BzCl +

1.97 g. KOH sepd. *dibenzoyldiaminoguanidine* (g), HN:C(NH.NHBz)_2 , pearly crystals from EtOH, m. $210-1^\circ$. If to the alk. liquid from which (g) was sepd. is added HCl until faintly acid a white cheesy substance, *sym-tetrazobenzoyldiaminoguanidine* (h), seps., white shining cryst. powder, m. 169° , sol. in H_2O and other solvents but if heated in liquids slightly acid or alk. it is hydrolyzed. On boiling (h) with $\text{H}_2\text{O.NH}_3$ is evolved and on concg. the soln. (NHBz)₂ seps. 1 mol. $\text{HCO}_2\text{H} + 1$ mol. (e) boiled 3 hrs. on the H_2O bath gave white needles of *N-aminoimidohydrotriazole hydrobromide* (i) (salt of (c) or (d)), m. $216-8^\circ$. (i) treated with the calcd. amt. of wet Ag_2O for 48 hrs., filtered and dried gave *N-aminoiminodihydrotriazole* (j), $\text{C}_2\text{H}_4\text{N}_4$, yellowish crystals, m. 208° ; its aq. soln. gives with AgNO_3 a white ppt. sol. in cold NH_3 or in HNO_3 . A soln. of (i) treated with picric acid ppts. the *picrate*, $\text{C}_2\text{H}_4\text{N}_4.\text{C}_6\text{H}_3\text{N}_3\text{O}_7$, minute shining crystals, m. 192° . 10 g. (e) treated with 9.19 g. $\text{Pb(NO}_3)_2$ in H_2O with warming sepd. PbBr_2 on cooling; the filtrate when concd. and recrystd. gave finally the *nitrate* of (e), $\text{C}_2\text{H}_4\text{N}_4.\text{HNO}_3$, as shining white needles, m. 194° . (i) treated with BzH and some drops of HBr seps. nothing but on making alk. with KOH the *benzylidene derivative* of (i), $\text{HN:C.NH.N:CH.N:CHPh}$, seps. as shining yellow laminas, m. $235-6^\circ$; treated with

AgNO_3 it gives a yellow ppt. sol. in HNO_3 and repptd. by NH_3 but sol. in excess. 10 g. (i) in 100 cc. cold H_2O treated with 4.4 g. KNO_3 at room temp. became orange-yellow, evolved much gas and pptd. a *nitroso derivative* (k), $\text{C}_2\text{N}_4\text{H}_2\text{NO}$, as yellow crystals that give Liebermann's reaction; it decomposes very easily from 170 to 220° , depending on the rate of heating. (k) treated with AgNO_3 gives a yellow ppt. insol. in NH_3 or HNO_3 . 6 g. diaminoguanidine nitrate (l), 7.5 cc. H_2O , 3.5 cc. glacial AcOH and 2 drops concd. HNO_3 heated 6 hrs. under a condenser on a H_2O bath gave a citron-yellow syrup which, evapd. several times after adding EtOH, gave *N-aminoiminomethylidihydrotriazole nitrate* (m), $\text{HN:C.NH.N:CMe.N.NH}_3.\text{HNO}_3$, white crystals, m. 184° . Equimol.

amts. of (m) + BaCO_3 in H_2O sepd. $\text{Ba(NO}_3)_2$; the mother liquor evapd. on the H_2O bath, extd. with EtOH, etc., gave *N-aminoiminomethylidihydrotriazole*, $\text{C}_2\text{H}_4\text{N}_4$, needles, m. 193° , with properties similar to those of (j). (l) treated in H_2O with satd. picric acid seps. *N-aminoiminomethylidihydrotriazole picrate*, $\text{C}_2\text{H}_4\text{N}_4.\text{C}_6\text{H}_3\text{N}_3(\text{NO}_2)_3\text{OH}$, minute yellow crystals, m. 189° (decompn.). (l) in H_2O and concd. H_2PtCl_6 sep. *N-aminoiminomethylidihydrotriazole chloroplatinate*, $(\text{C}_2\text{H}_4\text{N}_4\text{HCl})_2\text{PtCl}_4$, orange-yellow prismatic crystals, m. 226° .

E. J. WITZEMANN.

The detection of iodine in organic iodo derivatives and in mixtures with bromo and chloro derivatives by means of ammonium bromide. III. ICILIO GUARESCHI. *Atti accad. sci. Torino* 50, 803-8(1915).—In a preceding paper (C. A. 9, 2358-9) G. showed that by heating iodides with NH_4Br (as well as iodides mixed with much bromide or chloride) a trace of iodide could be detected. The results with organic I derivs. are now reported. There are many organic I derivs. in which no special reaction is needed for the detection of I since they readily decomp. on heating and evolve violet I vapors. Many others, however, fail to decomp. G. found that dry NH_4Br and sometimes NH_4Cl not only liberate the I from its organic compds. but also when these are iodonitro derivs. or are mixed Cl or Br derivs. or chloro- or bromonitro derivs. The more stable I derivs. heated with NH_4Br in a long straight glass tube develop I vapors which may be tested with starch soln. after cooling. MeI mixed in small quantities with NH_4Br (or NH_4Cl) gives I vapors with the starch test. A mixt. of little MeI with much PhBr boils $156-8^\circ$ but with NH_4Br gives a strong test for I. Much EtBr mixed with a little MeI gives a strong test for I when heated with NH_4Br . EtI or EtBr containing EtI give good tests for I with NH_4Br or NH_4Cl . A trace of EtI in CHCl_3 gave a strong test for I with NH_4Cl . EtI mixed with much $\text{C}_2\text{H}_4\text{Cl}_2$ (b. $41-2^\circ$) gave the test with NH_4Br . Similarly for mixts. of EtI with CH_2Cl_2 . CHBr_3 heated

with NH_4Br gave red-brown vapors and other products. The reaction is being studied further. CHBr_3 with NH_4Cl gives Br vapors. A mixt. of little EtI (1-2%) with CHBr_3 heated with NH_4Br gave violet vapors and a violet soln. in CHCl_3 . CHCl_3 with NH_4Br evolves Br vapors and leaves a metallic residue, but CHCl_3 mixed with EtI (1-2%) gives the I test as well as Br vapors. EtI mixed with CHCl_3Br_2 gives a good test for I. A trace of iso-AmI heated with NH_4Br gives an intense reaction for I; a trace of the preceding is easily detd. in *tert*-AmBr. PrI was easily detected in the bromide. PhI boiled with an equal amt. of NH_4Br (or NH_4Cl) gives a fine test for I; the reaction is probably $\text{PhI} + \text{NH}_4\text{Br} \rightarrow \text{PhBr} + \text{NH}_4\text{I}$ and $\text{NH}_4\text{I} \rightarrow \text{NH}_3 + \text{H} + \text{I}$ (H was not tested for). PhBr or PhCl containing a trace of PhI gave good tests for I. Likewise 1 drop of a mixt. (0.50 g. PhBr + 0.50 g. PhCl + 0.001 g. PhI) gave the test for I with 4 parts of NH_4Br . A trace of PhI mixed with $\alpha\text{-C}_{10}\text{H}_7\text{Br}$ with NH_4Br gave the test; heated without NH_4Br , the result was negative. A positive result was obtained with PhI in $\text{C}_2\text{H}_4\text{Cl}_2$. $p\text{-O}_2\text{NC}_6\text{H}_4\text{I}$ (0.001 g.) gave a sharp test with NH_4Br but a weak test without NH_4Br . Heating a mixt. of the above with the Br deriv. gave no test for I, but 1 part of the I deriv. with 100 parts of the Br deriv. in the presence of NH_4Br gave a strong test for I. PhI with $p\text{-BrC}_6\text{H}_4\text{Me} + \text{NH}_4\text{Br}$ (not so well with NH_4Cl) gave the I test. Positive results with mixts. of PhI with $\text{C}_6\text{H}_4(\text{NO}_2)_2$ or PhOH were obtained. Compds. such as PhNH_2 , $\text{IC}_6\text{H}_4\text{CO}_2\text{H}$, etc., which evolve I on heating, were not tested.

E. J. WITZEMANN.

Salts of some aminoazo compounds. L. CASALE AND MARIA CASALE-SACCHI. Univ. Turin. *Atti accad. sci. Torino* 50, 903-18 (1915); *Gazz. chim. ital.* 45, I, 490-501 (1915).—The study of aminoazo compds. derived from $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$ (cf. C. A. 9, 795) led to the observation that the sulfates of these have a chem. compn. different from the sulfates of analogous compds. studied by Weselsky and Benedikt (*Ber.* 12, 228). This has led C. and C.-S. to exam. the salts of the aminoazo compds. derived from $\alpha\text{-C}_{10}\text{H}_7\text{NH}_2$. The results reported are limited to the salts of H_2SO_4 , HCl and HNO_3 . All of the above aminoazo compds. form salts with H_2SO_4 in the ratio 1 mol. base : 1 mol. acid, but some also form neutral salts, *i. e.*, 2 mols. base : 1 mol. acid. With HCl both series are formed but the former are stable and the latter are unstable and are rapidly transformed into the former in air, with the exception of α -naphthaleneazo- α -naphthylamine, of which both are stable. With HNO_3 the former series is also stable and the 2nd unstable. The latter also undergo a characteristic scission on fusion which will be described in another paper. The same exception is found with HNO_3 derivs. The stable sulfates, hydrochlorides and nitrates all cryst. in green prisms with a reflex changing from red to violet, are sol. in common organic solvents containing OH, are insol. in Et_2O and in hydrocarbons. The analysis of the double nitrates by combustion gave unreliable values for N. The HNO_3 was detd. volumetrically, using Me red as indicator. Treating 4-phenylazo-1-naphthylamine (a) in dry Et_2O with H_2SO_4 in Et_2O or boiling the base with dil. H_2SO_4 (various concns.) always gave $\text{C}_{16}\text{H}_{13}\text{N}_3\cdot\text{H}_2\text{SO}_4$, recrystd. from EtOH or glacial AcOH , m. $214\text{-}5^\circ$. HCl gas in Et_2O added to (a) in Et_2O ppts. $\text{C}_{16}\text{H}_{13}\text{N}_3\cdot 2\text{HCl}$ as a greenish violet ppt., which, washed with dry Et_2O and dried rapidly over H_2SO_4 in the presence of HCl , is very unstable. The preceding loses HCl to give stable $\text{C}_{16}\text{H}_{13}\text{N}_3\cdot\text{HCl}$, m. 205° , either when left in the air or on crystg. from AcOH or EtOH . It is also obtained on boiling (a) with aq. HCl . 2 g. of (a) in 200 cc. dry Et_2O treated at 0° with 150 cc. of an 8.6% Et_2O soln. of HNO_3 seps. $\text{C}_{16}\text{H}_{13}\text{N}_3\cdot 2\text{HNO}_3$ as blood-red crystals which may be washed repeatedly with Et_2O without decompn. Left in the air or on crystg. from EtOH it loses HNO_3 to give $\text{C}_{16}\text{H}_{13}\text{N}_3\cdot\text{HNO}_3$. 4-o-Tolylazo-1-naphthylamine (b) in Et_2O with a satd. Et_2O soln. of H_2SO_4 or with an aq. soln. of H_2SO_4 of not less than 10% gives $\text{C}_{17}\text{H}_{15}\text{N}_3\cdot\text{H}_2\text{SO}_4$ (c), long green prismatic needles from AcOH , m. $195\text{-}6^\circ$, which in warm EtOH or AcOH

with 1 equiv. of (b) seps. $(C_{17}H_{15}N_3)_2 \cdot H_2SO_4$ (d), m. 163° (decompn.), on cooling, also obtained by boiling (c) with 2.5% H_2SO_4 . If H_2SO_4 containing 5% excess acid is added to (c) whether (c) or (d) is obtained on filtration will depend on the temp. of the soln. at the time of filtering. (b) treated like (a) with HCl gives $C_{17}H_{15}N_3 \cdot 2HCl$, dark green; crystg. the preceding from AcOH or boiling (b) with aq. HCl gives $C_{17}H_{15}N_3 \cdot HCl$. Likewise (b) treated with HNO_3 like (a) gives $C_{17}H_{15}N_3 \cdot 2HNO_3$ as a dark coffee-colored mass, decomp. on standing or on fusion; heated on the H_2O bath it explodes at $\approx 80^\circ$. The former compound still wet with Et_2O dissolved in hot EtOH seps. $C_{17}H_{15}N_3 \cdot HNO_3$, emerald-green prisms, m. 170° . *4-m-Tolylazo-1-naphthylamine* (e) treated with H_2SO_4 like (b) gave $C_{17}H_{15}N_3 \cdot H_2SO_4$, bronze-green rectangular laminas, m. 189° . (e) in dry Et_2O treated with a satd. Et_2O soln. of HCl gave only $C_{17}H_{15}N_3 \cdot HCl$, bright green prisms with a blue reflex which cryst. unchanged from EtOH or AcOH. (e) in Et_2O treated with a 8.6% HNO_3 soln. in Et_2O gave only $C_{17}H_{15}N_3 \cdot HNO_3$, green-violet, m. 172° . 17.2% HNO_3 solns. sep. a different nitrate, probably $C_{17}H_{15}N_3 \cdot 2HNO_3$, but too unstable for analysis. *4-p-Tolylazo-1-naphthylamine* (f) gave $C_{17}H_{15}N_3 \cdot H_2SO_4$ in either aq. or Et_2O solns.; green prismatic needles with a red reflex, m. 211° . (f) treated with HCl as with (b) gave $C_{17}H_{15}N_3 \cdot 2HCl$, violet cryst. ppt. with deep green reflex. (f) with aq. HCl or the preceding recrystd. from AcOH gave $C_{17}H_{15}N_3 \cdot HCl$, short grass-green prisms, m. 211° (decompn.). Et_2O solns. of (f) treated with $Et_2O \cdot HNO_3$ ppt. $C_{17}H_{15}N_3 \cdot 2HNO_3$, dark greenish coffee-colored, unstable. On standing or when crystd. the preceding gives $C_{17}H_{15}N_3 \cdot HNO_3$, violet prismatic needles, m. 163° ; it is also obtained from a soln. of (f) with aq. HNO_3 . 2 g. *4-o-anisylazo-1-naphthylamine* (g) in 200 cc. hot 5% H_2SO_4 on cooling seps. $C_{17}H_{15}N_3 \cdot H_2SO_4$, short olive-green needles m. 173° , more sol. in AcOH, EtOH and Me_2CO than the preceding sulfates, may also be obtained by treating (g) in $CHCl_3$ with a satd. $Et_2O \cdot H_2SO_4$ soln. (g) with HCl as above gives $C_{17}H_{15}N_3 \cdot O \cdot 2HCl$, coffee-colored crystals; $C_{17}H_{15}N_3 \cdot O \cdot HCl$, dark green metallic color, m. $194-5^\circ$. With HNO_3 as before (g) gives $C_{17}H_{15}N_3 \cdot O \cdot 2HNO_3$, dark green cryst. powder, unstable; gives $C_{17}H_{15}N_3 \cdot O \cdot HNO_3$ from EtOH as large emerald-green aggregates of prisms, m. 173° . 2 g. *4-o-phenethylazo-1-naphthylamine* (h), boiled in 200 cc. of 5% H_2SO_4 , seps. $C_{18}H_{17}N_3 \cdot O \cdot H_2SO_4$, grass-green prismatic crystals from EtOH, loses its luster at 155° , browns and m. 182° ; the same salt was obtained from the Et_2O solns. $C_{18}H_{17}N_3 \cdot O \cdot 2HCl$ was obtained as with the others; on decompn. it gives $C_{18}H_{17}N_3 \cdot O \cdot HCl$ but this salt is obtained by dissolving (h) in hot dil. HCl and seps. on cooling as bright green prismatic needles, m. 195° . $C_{18}H_{17}N_3 \cdot O \cdot 2HNO_3$ from (h) was similar to this deriv. of (g) and recrystd. from EtOH gave $C_{18}H_{17}N_3 \cdot O \cdot HNO_3$ (or from aq. HNO_3 + (h)), m. $158-9^\circ$. Powdered *4-naphthaleneazo-1-naphthylamine* (i), boiled with dil. H_2SO_4 or by mixing the Et_2O solns., gave $C_{20}H_{15}N_3 \cdot H_2SO_4$, green prismatic needles with a red reflex, m. 163° . (i) with HCl as above gave $C_{20}H_{15}N_3 \cdot 2HCl$ which was recrystd. unchanged from AcOH or EtOH containing 1% HCl as green prisms, browns 190° , m. $201-2^\circ$; the preceding seps. $C_{20}H_{15}N_3 \cdot HCl$ from AcOH or EtOH solns., green-black opaque needles, browns without melting above 230° . $C_{20}H_{15}N_3 \cdot 2HNO_3$ seps. as dark green crystals with a bronze reflex, is stable like the 2 HCl deriv., explodes $139-40^\circ$. *4-o-Nitrophenylazo-1-naphthylamine* (j), boiled with aq. H_2SO_4 (10%), gives $C_{18}H_{13}N_4 \cdot O_3 \cdot H_2SO_4$ which can only be recrystd. unchanged from AcOH or EtOH containing 1% H_2SO_4 as coffee-colored prisms with a green reflex, m. $217-8^\circ$. Recrystd. from AcOH or EtOH the preceding seps. $(C_{18}H_{13}N_4 \cdot O_3)_2 \cdot H_2SO_4$, the neutral sulfate, as brick-red needles, m. 200° . (j) in Et_2O with a satd. Et_2O soln. of HCl gives $C_{18}H_{13}N_4 \cdot O_3 \cdot HCl$, brown. The 2 HCl deriv. is apparently not formed. (j) in Et_2O treated with 8.6% HNO_3 in Et_2O seps. $C_{18}H_{13}N_4 \cdot O_3 \cdot HNO_3$, grass-green crystals, m. $165-6^\circ$.

E. J. WITZEMANN.

The crystalline form of some derivatives of benzene. VIII. E. E. ARTINI.
Rend. ist. Lombardo sci. lett. [2] 48, 779-89(1915).—For methods of prepn. cf. Körner

and Contardi (cf. *C. A.* 8, 1761). 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{Cl}_2$, m. 114° , belongs to the monoclinic system, prismatic class, $a:b:c = 1.9310:1:1.4097$, $\beta 88^\circ 49'$; distinct exfoliation was not observed; the planes of the optical axes are parallel to the plane of symmetry. 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{ClBr}$, m. 114.5° , belongs to the same system and class, $a:b:c = 1.9472:1:1.3996$, $\beta 87^\circ 48'$, no exfoliation; the planes of the optical axes are parallel to the plane of symmetry. 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{Br}_2$, m. 143° , same system and class, $a:b:c = 0.5017:1:0.6775$, $\beta 86^\circ 25'$; the habit of crystn. is quite different in different solvents. The exfoliation is perfect. The plane of the optical axes is parallel to the plane of symmetry. 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{BrI}$, m. 140° , same system and class, $a:b:c = 0.4934:1:0.6774$, $\beta 87^\circ 5'$; the faces are not plane and prevented perfect measurement. The laminae of exfoliation are curved. All attempts to obtain measurable crystals of 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{ClI}$, m. 100° , failed. Such results as were obtained were nearly identical with those of the di-Br deriv. 1,4,2,6- $\text{C}_6\text{H}_2(\text{NO}_2)_2\text{I}_2$, m. 155° , same system and class, $a:b:c = 0.6103, 1:0.7908$, $\beta 66^\circ 56'$; exfoliation is easy and perfect. A comparison of the various members of this series shows that the di-Cl and ClBr derivs. are perfectly isomorphous with each other. Similarly the di-Br and BrI derivs. are isomorphous. Likewise the last 2 are probably also isomorphous with the ClI deriv. (observations imperfect). The more complex but remarkable morphologic relations existing between the 2 isomorphous groups which appear from a comparison of the angular values and from the topic axes is discussed in the summary.

E. J. WITZEMANN.

Synthesis of diazines and some new derivatives of chloral and bromal. SR. MINOVICI AND V. TH. BENTR. Univ. Bucarest. *Bull. sect. sci. acad. roumaine* 4, 185-94(1915).—M. and B. have condensed halogen-substituted aliphatic aldehydes, especially chloral and bromal, with PhNHCH_2CN (A), with apparent formation of *p*-diazine. Previously they have shown that (A) condenses with aromatic aldehydes to form imidazoles, but does not react with unsubstituted aliphatic aldehydes. The cyanohydrin of anisaldehyde reacted equally as well, but cinnamic and salicylic aldehydes did not give enough product to analyze. The reaction is theoretically explained by intermediate formation of imidazole which loses HCl to form the diazine. M. and B. obtain (A) in 80% yield by keeping 50 g. mandelic nitrile in 50 cc. abs. alc. satd. with NH_3 for 24 hrs. at 0° in an hermetically sealed flask. After filtering the resulting cryst. mass, and drying in a desiccator, it is pptd. from cold CHCl_3 with ligroin. 2,3-Dichloro-6-phenyl-*p*-diazine, N:CCl.CCl:N.CH:Ph , obtained by vigorous interaction

of 5.1 g. (A) and 6.6 g. anhydrous chloral in 20 cc. abs. Et_2O and recrystn. from 90% alc. (Yield, 75%.) Long, thin, golden yellow crystals, m. 102° , easily sol. in EtOH , Et_2O , CHCl_3 , ligroin, C_6H_6 and AcOH , mol. wt. (in freezing C_6H_6) 225. With alc. KOH or NaOH it is colored green to violet, then brown; acidulating the colored alk. soln gives an intense red which can be extd. with Et_2O . 2,3-Dibromo-6-phenyl-*p*-diazine, $\text{N:CBr.CBr:N.CH:CPh}$, from 7 g. (A) and 7 g. bromal, yellow acicular crystals, m. 120° .

mol. wt. 315. 2,3-Dichloro-6-methoxyphenyl-*p*-diazine, $\text{N:CCl.CCl:N.CH:C(C}_6\text{H}_4\text{OMe)}$, from chloral and anisaldehyde cyanohydrin, yellow acicular crystals, m. 144° , mol. wt. 254. 2,3-Dibromo-6-methoxyphenyl-*p*-diazine, $\text{N:CBr.CBr:N.CH:CC}_6\text{H}_4\text{OMe}$, from bromal and anisaldehyde cyanohydrin, crystals, m. 160° , mol. wt. 345.

L. H. CHERNOFF.

Some new oxidation products of cholesterol. AND TH. ZENOVICI-EREMIE. Univ. Bucarest. *Bull. sect. sci. acad. roumaine* 5(1915).—By the action of 50 g. perhydrol in 100 cc. of 20% H_2O_2 solution (x) in 200 cc.

AcOH, 2 new compounds are obtained: (A) $C_{24}H_{40}O_4$, and (B) $C_8H_{10}O_4$, which cryst. from dil. acetone. (A) seps. first in 7% yield; it is easily sol. in Et_2O , C_6H_6 , $CHCl_3$, and ligroin, less sol. in EtOH and MeOH, insol. in H_2O and alkali hydroxides, $\alpha_D^{20} = 41.47$, mol. wt. (in AcOH) 382. In Salkowski's test the $CHCl_3$ remained colorless but the acid was colored yellow. The Liebermann-Burchard test gave only an intense red-violet. The Lifschutz reaction for oxycholesterol also failed. M. and Z.-E. therefore conclude that (A) does not contain hydroxyl, phenolic, or ketonic groups, neither is it an ozonide or peroxide. They have, however, established the presence of an Ac group. (A) does not add halogen, therefore the double bond in (x) had disappeared. With HCl and HBr, (A) gives the cryst. compds. $C_{12}H_{23}Cl$, m. 150° , and $C_{12}H_{23}Br$, m. 130° . Mol. wt. (in AcOH) 220. (B), from the mother liquor of (A), obtained as an oil which resinsified in contact with air, was purified by pptg. from aq. KOH, with HCl, dissolving in Et_2O , and evapg. *in vacuo*. (B) is easily sol. in EtOH, Et_2O , $CHCl_3$, acetone, and aq. alkali, insol. in H_2O and has an acid reaction. The AcOH soln. gives no color with H_2SO_4 , but the Ac_2O soln. gives with H_2SO_4 an intense red which changes to green. The same color is produced in the Liebermann-Burchard reaction. The Salkowski reaction gives a yellow color in the upper layer and a green fluorescence in the lower. Attempts to combine (B) with digitonin failed. M. and Z.-E. therefore conclude that (B) is not oxycholesterol, but a resin acid; acid no. 84.165, sapon. no. 134.2. Under slightly different conditions, from 10 g. (x) in 200 cc. of 20% H_2SO_4 and 150 cc. perhydrol, an oily substance (C) is formed which solidifies by addition of H_2O . (c) is sol. in Et_2O , EtOH and $CHCl_3$, but insol. in H_2O . Analyses—C 69.32–70.70%; H 10.50–10.61%. If to 10 g. (x) in 100 cc. AcOH is added 100 cc. of 20% H_2SO_4 and 50 cc. perhydrol, a cryst. substance (D) is formed, m. 200° , containing C 75.10, H 10.95%. Another cryst. substance designated by the authors as (E) was obtained by the action of 100 cc. of 20% H_2SO_4 on 10 g. (x) in 100 cc. AcOH; needles from acetone, m. $110-1^\circ$. Analysis agrees with that for cholestanol acetate previously obtained by Willstätter and Mayer (C. A. 3, 2807) but the compd. is not the same since it forms cryst. Cl and Br derivs., m. $95-7^\circ$ and $116-18^\circ$, resp.

L. H. CHERNOFF.

Chemical constituents of the fruits of *Evodia rutaecarpa*. Y. ASAHINA AND K. KASHIWAKI. *J. Pharm. Soc. Japan* 1915, No. 405, 1293; cf. C. A. 10, 250.—Upon treatment of the evapd. acetone ext. with NaOH, an oily layer, a dark-colored H_2O soln. and a suspended cryst. mass were obtained. The oily layer consisted of a terpene and polymerization products, from which the former was purified by means of distn. *in vacuo* and with steam. The pure terpene, $C_{10}H_{16}$, which was named "evodene," is a clear liquid, b. $67-8^\circ$, $[d]_D^{20}$ 0.7989, n_D^{19} 1.4843, unstable towards air and heat and absorbs O readily. With Na and alc. a dihydro deriv. is formed, which forms an unstable liquid tetra-Br compd. Upon hydrogenation, 3 mols. of H are absorbed with the formation of 2,6-dimethyloctane. A. and K. conclude that the terpene is identical with ocimene. Acidification of the alk. soln. yielded a dark amorphous ppt. containing some evodene and a phlobaphene-like substance. The cryst. mass was sepd. by fractional crystn. from alc. into 2 constituents, *evodiamine* and *rutaecarpine*. The former is the less sol. It crysts. in light yellow plates, m. 287° , of the compn. $C_{19}H_{17}ON_3$, reacts with concd. H_2SO_4 , giving an orange color changing to a red-brown and on long standing or on diln. with H_2O to blue. HCl reacts somewhat similarly. The blue color is destroyed by alkalis with the formation of a dirty blue ppt. It is hydrolyzed by boiling concd. alc. KOH into *N*-methylantranilic acid and a base, $C_{11}H_{10}N_2$, difficult to cryst. but forming easily crystallizable salts; e. g., the picrate, m. 242° . It does not respond to the pine shaving reaction. On boiling with alc. HCl *evodiamine* is an isomer, *isoevodiamine*, $C_{19}H_{17}ON_3 \cdot H_2O$, m. $155-6^\circ$; its hydrochloride in hexagonal or rhombic plates, from H_2O in fine prisms. The

hydrated salt m. 255-6° and the anhydrous salt 265-7°. Concd. H_2SO_4 colors it yellow. It is hydrolyzed by boiling concd. alc. KOH into methylanthranilic acid and a base, $\text{C}_{10}\text{H}_{13}\text{N}_2$, having a definite HCl salt, a picrate, m. 242-3°, and forming with Ac_2O an Ac deriv., m. 163°; it responds to the pine shaving reaction. Rutaecarpine, $\text{C}_{18}\text{H}_{17}\text{ON}_2$, crystg. in light yellow needles, m. 258°. Toward reagents it reacts in many ways like evodiamine. With concd. H_2SO_4 and warm concd. HCl it forms a yellow color. A. and K. conclude that evodiamine is methyl-dihydrotutaecarpine. An abstr. in German precedes the article.

H. W. DAUDT.

Synthesis of peonolglucoside. Y. ASAHINA AND G. SHIRABE. *J. Pharm. Soc. Japan* 1915, No. 405, 1293; cf. Péron, *C. A.* 5, 2494.— β -Peonolglucoside was prepd. from peonol and β -acetobromoglucose. The white crystals, $\text{C}_{20}\text{H}_{32}\text{O}_6$, $(\text{OMe})\text{Ac} \cdot 2\text{H}_2\text{O}$, lose their H_2O of crystn. at 59° and m. 118°, $[\alpha]_D -79^\circ$. Acids and emulsin hydrolyze it into glucose and peonol. Tetraacetopeonolglucoside, crystg. in needles or plates, m. 146°, $[\alpha]_D -44.1^\circ$, was prepd. An abstr. in German precedes the article.

H. W. DAUDT.

The mechanism of the action of trisodium phosphate on glycerol α -monochlorohydrin. O. BAILLY. *Compt. rend.* 161, 677-80(1915).—A mixt. of Na_3PO_4 and $\text{CH}_2\text{ClCH}(\text{OH})\text{CH}_2\text{OH}$ was allowed to stand at 18° and the amts. of NaCl , Na_3PO_4 , and $\text{Na}_2\text{C}_2\text{H}_4(\text{OH})_2\text{PO}_4$ detd. at various intervals. The alkalinity of the reaction was explained by assuming that the reaction took place in 2 stages whereby Na_2HPO_4 was formed which reacted with the glycerol deriv. to form the $\text{Na}_2\text{C}_2\text{H}_4(\text{OH})_2\text{PO}_4$. This process gives the α - or the β -compds. Cf. *C. A.* 8, 3023.

R. L. SIBLEY.

Crystallographic peculiarities of aniline nitrate. FRÉD. WALLERANT. *Compt. rend.* 161, 470-80(1915).—This is orthorhombic at ordinary temp. It crysts. from H_2O in very flat plates, conforming to the faces g^1 . The faces m and $b^{1/2}$ are very much reduced. Crystd. from alc., it shows only the faces $b^{1/2}$; the crystals are octahedra without any traces of the faces g^1 . At 97.6°, it goes over into monoclinic crystals. This transformation is reversible and indirect. On heating an orthorhombic plate of cleavage, it transforms into monoclinic fibers of indefinite orientation; but on cooling again, it forms again an orthorhombic plate with its original orientation. The transformation shows no supercooling or superfusion, but a notable latent heat.

P. M. GIESY.

Synthesis of some terpeneols and terpins. O. WALLACH. Univ. Göttingen. *Nachr. kgl. Ges. Göttingen* 1915, 1-27; through *Chem. Zentr.* 1915, II, 824-9.—I. With HANS BERTHOLD. The satd. *hydroxyketone* (I), which is an intermediate product

in the oxidation of β -terpineol to Δ^1 -tetrahydro-*p*-acetyl-toluene (a), is also obtained by shaking (a) 6-8 weeks with 4% H_2SO_4 . *Semicarbazone*, m. 197-8°. *Dibromide* of (a), obtained by bromination in AcOH, m. 61°; the Br cannot be split off with aq. KOH; boiling in AcOH produces strong resinification and only a little $\text{AcC}_6\text{H}_4\text{Me}$ is formed. Nascent H reduces (a) to the lower homologous terpeneol (II) (*Ann.* 324, 93) which, shaken with dil. H_2SO_4 , yields 1,8-dihydroxy-1-methyl-4-ethylcyclohexane, m. 94-5°, while with Pd-H (a) gives 8-hydroxy-1-methyl-4-ethylcyclohexane, b. 203-5°, $d_{17} 0.9110$, $n_D 1.46405$, mol. refraction 43.01. (a), obtained from β -terpineol, when treated with MeMgI , yields α -terpineol. *Homo- α -terpineol* (III), similarly obtained from (a) and EtMgI , b. 235-7°, $d_{20} 0.9390$, $n_D 1.4850$, mol. refraction 51.28. *Dibromide*, oil; warming with NaOMe produces a homologous pineol, which, however,

goes over into *p*-methylisobutylbenzene. (III) and KMnO_4 yield a glycerol $\text{C}_{11}\text{H}_{19}(\text{OH})_3$, b. 140–50°. Homologous 1,8-terpin (IV), from (III) shaken with dil. H_2SO_4 , m. 65–7°.

(IV)

(V)

(VI)

Homologous menthanol, $\text{MeC}_8\text{H}_{16}\text{CMeEtOH}$, from (III) and Pd-H , b. 106–8°, b. 223–5°, d_{15} 0.9115, n_D 1.4683, mol. refraction 51.88. Phenylurethan, m. 115–20°. It is apparently a mixt. The homo- α -terpineol (V) obtained from ethylnopinol (C. A. 2, 2085), b. 226–7°, d_{15} 0.943, n_D 1.4811, m. 92–4°, is isomeric with (III); several days' shaking with 5% H_2SO_4 yields 1,8-dihydroxy-1-ethyl-4-isopropylcyclohexane, m. (with H_2O of crystn.) 75–6°. II. Preparation of homologous benzene hydrocarbons from α -terpineols (menthenols). With HANS BERTHOLD. The unsatd. alcs. and 1 mol. Br_2 in AcOH are boiled until the evolution of HBr ceases, distd. with steam, shaken with KMnO_4 and distd. over Na . Cymene, obtained in 86% yield from α -terpineol dibromide, b. 174–5°, d_{20} 0.8575, n_D 1.4909. 1,4-Methylethylbenzene, from Δ^1 -1-methyl-7-hydroxy-4-ethylcyclohexene, b. 161–2°, d_{22} 0.862, n_D 1.4918, mol. refraction 40.37. 1,4-Methylisobutylbenzene, from (III) or the homologous pinol, b. 196–7°, d_{15} 0.8640, n_D 1.4917, mol. refraction 49.67. 1,4-Ethylisopropylbenzene, from (V), b. 197–8°, d_{20} 0.864, n_D 1.4846, mol. refraction 49.06. III. 1-Methyl-4-propyl-3-cyclohexenone and -3-cyclohexanone. With LOUIS AUGSBURGER. Δ^1 -1-Methyl-4-propylcyclohexene, obtained by warming 4,4-Pr(HO) $\text{C}_6\text{H}_4\text{Me}$ with dil. H_2SO_4 , b. 173–6°; nitrosochloride, m. 134–5°; nitrosate, m. 119°; nitrolpiperidide, m. 150–2°. The nitrosochloride by loss of HCl yields the oxime, liquid, of Δ^1 -1-methyl-4-propyl-3-cyclohexenone, b. 220–3° (darkening), b. 95–8°, d_{20} 0.9225, n_D 1.4732, mol. refraction 46.24; semicarbazone, m. 153–4°. Reduction of the unsatd. ketone by Skita's method gives the hexanone (normal menthone) (c), b. 215–7°, d_{15} 0.8960, n_D 1.4511, does not smell like menthone, mol. refraction 46.29. Semicarbazone, m. 149–52°. Oxime, m. 87–8°. Oxidation with CrO_3 yields a keto acid with the same C content, whose semicarbazone, $\text{C}_{11}\text{H}_{21}\text{O}_2\text{N}_3$, m. 156–8°. 1,4-Methylcyclohexene propane, $\text{MeC}_8\text{H}_{15}\text{CH}_2\text{Et}$, from the condensation product of bromobutyric ester and *p*-methylcyclohexanone (C. A. 2, 2083), b. 173–4°, d_{20} 0.8110, n_D 1.4571, mol. refraction 46.41. Nitrosochloride, m. 138–40°. Nitrolpiperidide, m. 148–9°. The nitrosochloride yields the oxime, m. 105–6°, of the unsatd. ketone, b. 230–1°, which by the Skita method yields the satd. ketone, b. 210–1°, d_{15} 0.9090, n_D 1.4541, mol. refraction 45.89; semicarbazone, m. 182–3°; oxime, m. 95–6°. (c) is also obtained by the Skita method from 1,1-methyl-4-allyl-3-cyclohexanone, smells like isonitriles; oxime, m. 99–100°; semicarbazone, m. 125–8°. IV. Conversion of the thujaketo acids into tanacetophorone, and 1,3-isopropylcyclopentanone. With HANS WOERLITZER. A new method for effecting the above conversion (cf. C. A. 6, 1595) consists in esterifying the acids with alc. HCl and treating the resulting product with Na alcoholate. $\Delta^{2,6}$ -1-Methyl-3-isopropylcyclopentadiene, from tanacetophorone and MeMgI , unstable in the air, b. 166–7°, d_{21} 0.845, n_D 1.4913, mol. refraction 41.84. Bicycloisopropylpenteneisopropylpentanone (d), from 5 g. isopropylcyclopentanone allowed to stand 2 days with 0.4 g. Na in 10 cc. cold alc., m. 77–8°; oxime, $\text{C}_{16}\text{H}_{29}\text{NOH}$, begins to m. 125°, m. completely 149°; semicarbazone, m. 192.5°. Reduction with Pd-H in MeOH gives the satd. ketone, b. 157–65°, solidifies in a freezing mixt.; oxime, m. 136° (decompn. begins at 120°). Reduction of the satd. or unsatd. ketone with Na and alc. gives bicycloisopropylpentylisopropylpentanol, b. 160–4°, solidifies in the cold. Phenylurethan, m. 115–20°. the cold soln. of the Na deriv. of isopropylcyclopentanonecarboxylic reduction of the tanacetophoronecarboxylic

ester) is treated with 1 mol. PhN_2Cl , NaOAc ppts. from the resulting clear yellow soln. a light yellow *1,3-isopropylcyclopentanone phenylhydrazone*, yellow crystals with metallic luster from AcOEt , m. 233° , deep red crystals of somewhat lower m. p. from hot AcOH . Treatment of the ketone with $\text{BrCH}_2\text{CO}_2\text{Et}$ and Zn in C_6H_6 gives, besides the HO ester, the compd. (d). The HO acid $\text{C}_{10}\text{H}_{18}\text{O}_2$ was obtained only as an oil which, boiled several hrs. with 2 parts Ac_2O and distd. with steam, gave *1,3-isopropylcyclopentene-acetic acid*, $\text{Me}_2\text{CHCH}_2\text{H}:\text{CHCO}_2\text{H}$. V. *Dihydrofencholene alcohol*. With FRIEDRICH POHL. Treatment of fencholeneamine with HNO_2 yields, besides hydrocarbon, not the expected primary unsatd. alc. but a tertiary alc. (probably VI), $b_{12} 90-3^\circ$, reduced in Me_2CO by Paal's method to *dihydrofencholene alcohol*, b. $204-7^\circ$, $b_{17} 95-6^\circ$, $d_{15} 0.898$, $n_D 1.4571$, oil of a pleasant odor, very easily volatile with steam, stable towards CrO_2 ; heated 20 min. at $185-95^\circ$ with ZnCl_2 , it loses H_2O to form the hydrocarbon, $\text{C}_{10}\text{H}_{16}$, b. $165-7^\circ$, $d_{20} 0.8035$, $n_D 1.4479$, mol. refraction 45.97. *Fencholeneamine hydrate*, $\text{C}_{10}\text{H}_{18}(\text{OH})\text{CH}_2\text{NH}_2$, $b_{18} 134^\circ$, $b_{1-2} 112-3^\circ$; on standing with NaNO_2 in cold AcOH it gives a small amt. of *dihydroxyfencholane*, needles from C_6H_6 , m. $103-4^\circ$, isolated by extg. with CHCl_3 the reaction mixt. freed from fencholene alc. with Et_2O . VI. *Behavior of cyclomethylamines*. The cyclomethylamines with HNO_2 give, not only the corresponding alcs., but also alcs. of higher ring systems (*Terpene u. Campher*, 2nd ed., p. 154). To det. whether an unsubstituted CH_2NH_2 group is necessary for this peculiar reaction, the base *p*- $\text{MeC}_6\text{H}_{10}\text{HMeNH}_2$, b. $193-4^\circ$, was prepd. by reduction of the oxime, m. $58-9^\circ$, of *p*- $\text{MeC}_6\text{H}_{10}\text{Ac}$; *urea*, m. $180-1^\circ$; *phenylurea*, m. 98° . With HNO_2 it gives the corresponding sec. alc. The unsatd. acid, m. 153° , obtained in the usual way from 1,5-dimethyl-3-cyclohexenone, is reduced by the Skita method to *1,5-dimethylcyclohexane-3-acetic acid*, b. $256-8^\circ$, $b_{18} 137-9^\circ$, $d_{20} 0.962$, $n_D 1.4611$. *Methyl ester*, b. $230-1^\circ$, $b_{14} 116-8^\circ$, $d_{18} 0.9215$, $n_D 1.4476$, mol. refraction 57.48. *Amide*, m. $141-3^\circ$ or $146-8^\circ$ (according to the manner of heating), obtained from the chloride, together with some *nitrile*, b. 225° . With Br and alkali the amide gives the base *3,5-Me_2C_6H_3CH_2NH_2*; *hydrochloride*, m. 240° ; *urea*, m. 154° ; *acetyl derivative*, m. 79° . The HCl salt with NaNO_2 yields an oil, b. $195-205^\circ$, giving with CrO_3 a cyclic ketone-like compd.; *semicarbazone*, $\text{C}_{10}\text{H}_{19}\text{ON}_3$, whether the ketone has the structure $2,4,6\text{-Me}_3\text{C}_6\text{H}_3\text{O}$ or $\text{MeCH.CH}_2\text{CHMe.CH}_2\text{CH}_2\text{CH}_2\text{CO}$ is uncertain.

CHAS. A. ROUILLER.

Oxidation of ethyl alcohol by means of potassium permanganate. WILLIAM L. EVANS and JESSE E. DAY. *J. Am. Chem. Soc.* 38, 375-81(1916).—Into 30 g. KMnO_4 in 1000 cc. H_2O and varying amts. of KOH at 50° , kept vigorously stirred, was slowly dropped 9.21% aq. alc. until the reduction of the KMnO_4 was complete and the reaction mixt. was then analyzed for CO_2 , $(\text{CO}_2\text{H})_2$ and AcOH . Recalcg. the data on the basis of 5 g. EtOH completely oxidized, the yield in g. of the above 3 products ranges from 0.071, 0.6000 g., resp., for the soln. with no KOH to 1.716, 3.049, 3.139 g. with 579.3 g. KOH . Plotting the yields of the 3 products against the amt. of KOH , it is found that the $(\text{CO}_2\text{H})_2$ curve becomes practically parallel to the KOH axis from about 150 g. up, that for CO_2 from about 175 g. and that for AcOH from about 225 g. Discussion of the results is reserved for a later paper in which will be reported measurements at 25° and 75° .

CHAS. A. ROUILLER.

Amines. V. Formation of Schiff bases from β -phenylethylamine and their reduction to alkyl derivatives of this amine. NORMAN A. SHEPARD and ARTHUR A. TICKNOR. *J. Am. Chem. Soc.* 38, 381-7(1916); cf. Johnson, *C. A.* 8, 1279.—The following amines have been prepd. to compare their pharmacological activity with that of $\text{PhCH}_2\text{CH}_2\text{NH}_2$ (a) and *p*- $\text{HOC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{NH}_2$. $\text{PhCH}_2\text{CH}_2\text{N}:\text{CHPh}$, from (a) and BzH (Barger and Walpole, *C. A.* 4, 1018), has been obtained in 91% yield of purified material (found, 6.8% N); it b_{17-9} , $188-9^\circ$, and solidifies to stout prisms, m. $41-2^\circ$

(B. and W., about 70°); 15 g. in 300 g. alc., slowly treated with 40 g. Na, carefully dild. with H₂O, strongly acidified with HCl and concd., gives 18 g. of PhCH₂CH₂NHCH₂Ph.HCl, plates from H₂O, m. 265-6° (Fischer, *Ber.* 29, 211 (1896)). *p*-Methoxybenzal- β -phenylethylamine, in 13 g. yield from 8.1 g. (a) condensed with MeOC₆H₄CHO, b₁₁ 224-5°, m. 34-5°, reduced by Na and alc., with good yield, to the *bensyl compound* (b), oil; *hydrochloride*, plates from H₂O, m. 266-7°. *p*-Hydroxybenzal compound, in 83.0% yield from (b) and HOC₆H₄CHO at 100°, yellow prisms from 95% alc. or C₆H₆, m. 188-90°; *bensyl compound*, hexagonal tables from alc., m. 135-6°, isolated in 64.5% yield as the *hydrochloride*, leaflets from dil. HCl, prisms from 50% alc., m. 225-6°; the base is also obtained as the HI salt by boiling 4 g. (b) 1 hr. with 35 cc. HI. *o*-Hydroxybenzal- β -phenylethylamine, in practically quant. yield from (a) and HOC₆H₄CHO 1 hr. at 100°, yellow prisms from alc., m. 45.5°; 15 g. in 20 parts boiling alc. treated with 2.5 parts Na, cooled, dild. with H₂O, treated with 300 cc. of 1:1 HCl, evapd. to dryness at 100°, filtered from the oil, the cryst. residue (2.7 g.) freed from NaCl by trituration with cold H₂O, treated with NH₄OH, extd. with Et₂O and satd. with HCl gas, gives the *bensylamine hydrochloride*, stout prisms or blocks, m. 130°, easily dissociated by heating and by warming with H₂O; the aq. soln. yields 2.5 g. (b), resulting from the hydrolysis of the unreduced Schiff base. In alc. with 1-2% H₂O there is practically no reduction. *3*-Methoxy-4-hydroxybenzal compound, from vanillin and (a) (cf. Decker and Becker, *C. A.* 7, 1513), yellow columns or prisms from alc., m. 112-3° (D. and B. describe it as colorless plates, m. 108-9°); the alc. mother liquors yield 0.3 g. of a dark red substance sepg. from alc. in rectangular plates, m. 220-1°, insol. in NaOH and HCl, with 8.57% N, also formed in 0.5 g. yield in the condensation of *p*-HOC₆H₄CHO with (a). *Bensyl compound*, needles from 95% alc., m. 99-100°, isolated as the *hydrochloride*, needles from dil. HCl, m. 180°, in 47% yield.

CHAS. A. ROULLER.

New case of tautomerism: 1,4,5,6-tetrahydroxynaphthalene. A. S. WHEELER AND V. C. EDWARDS. *J. Am. Chem. Soc.* 38, 387-93 (1916); cf. *C. A.* 9, 308; Zincke and Schmidt, *Ann.* 286, 27 (1895).—Zincke and Schmidt found that solns. of their yellow 1,4,5,6-C₁₀H₄(OH)₄ (a), m. 154°, soon turn red in the air and deposit red crystals of the same m. p. and yielding the same derivs. as the yellow form. By means of not too strongly basic ketone reagents, W. and E. have now obtained mono- and diketone derivs., indicating the existence of 2 tautomeric forms, but, unlike the hydrojuglones, the keto and enol forms cannot be obtained pure and all efforts to distinguish differences in behavior of the yellow and red forms proved unavailing. The development of the red color is largely prevented by substituting N for air, or by the addition of a little SnCl₄. Single red crystals appear yellow under the microscope, but a mass of crystals, viewed directly, as well as the solns., are dark red. The com. naphthazarin (Badische) used as starting point was purified by sublimation under 2-10 mm., in an electrically heated app.; yield, 70%. From 20 g. of the purified product boiled 20 min. with 5 l. of 12% HCl and 100 g. SnCl₄ is obtained 18 g. (a), m. 153-4° without recrystn. Attempts to prep. an oxime by heating 0.2 g. (a) with 0.075 g. NH₂OH.HCl and 0.10 g. BaCO₃ in 15 cc. alc. for 4 hrs. and letting stand 4 days gave only a black amorphous ppt. When, however, 1 g. (a) in 100 cc. alc. is treated with 0.57 g. H₂NCONHNH₂.HCl and 0.51 g. KOAc in 3 cc. H₂O, crystn. begins in 4 hrs. and is complete in 1 day, 1.05 g. of the *semicarbazone*, C₁₀H₁₁O₄N₃, sepg. in yellow prisms, evolving violet vapors about 170-200°; softening and blackening; for analysis, it is freed as completely as possible of the small amt. of accompanying amorphous impurities by extg. with large amts. of solvents. *Phenylsemicarbazone*, obtained in 2.7 g. yield after 24 hrs. from 2 g. (a) and 1.6 g. PhNHCONHNH₂ in 250 cc. alc., needles, m. 218° (decompn.), evolving violet vapors; the red and yellow forms react with the same rapidity and give the same

amt. of product, both in alc. and in CHCl_3 . *Diphenylsemicarbazone*, $\text{C}_{20}\text{H}_{16}\text{O}_2\text{N}_4$ (not quite pure; found, 17.04% N), hexagonal plates, darkens 280° , condenses $285-7^\circ$ as a dark liquid on the upper walls of the capillary, is obtained in 1.17 g. yield in 3 days from 0.5 g. (a) and 0.8 g. PhNHCONHNH_2 in 70 cc. alc.; Me_2CO exts. from the product a small amt. of substance sepg. in scales, m. $120-1^\circ$. *p-Bromophenylsemicarbazone*, in 1.47 g. yield after 8 days from 2 g. (a) and 2.4 g. $\text{BrC}_6\text{H}_4\text{NHCONHNH}_2$ in 450 cc. alc., yellow needles from Me_2CO , decomp. $220-3^\circ$. *p-Nitrophenylsemicarbazone*, in 1.23 g. yield after 40 hrs. from 1.5 g. (a) and 1.2 g. $\text{O}_2\text{NC}_6\text{H}_4\text{NHCONHNH}_2$ in 200 cc. alc., yellow needles or prisms from Me_2CO , begins to decomp. 234° , gives violet vapors about 234° . *Benzoylhydrazone*, in 0.51 g. yield after 4 days from 0.5 g. (a) and 0.4 g. BzNHNH_2 in 60 cc. alc., yellow needles from $\text{Me}_2\text{CO}-\text{H}_2\text{O}$, decomp. $170-85^\circ$. *p-Nitrobenzoylhydrazone*, in 0.2 g. yield from 0.5 g. (a) and 0.5 g. $\text{O}_2\text{NC}_6\text{H}_4\text{CONHNH}_2$ in 100 cc. alc., warmed 4 hrs. and allowed to stand 2 days, yellow needles from Me_2CO , m. $220-4^\circ$ (decompn.). Me_2SO_4 in 10% NaOH and CH_3N_3 in Et_2O give amorphous products but 0.2 g. (a) and 0.2 g. CH_3N_3 allowed to stand 1 week in CHCl_3 and evapd. yield 0.18 g. of a cryst. material. From 1.5 g. (a) boiled 75 min. under 0.5 atm. excess pressure with 500 cc. MeOH and 15 cc. of concd. H_2SO_4 and poured into hot H_2O is obtained a large crop of reddish yellow needles, m. $115-40^\circ$; analysis indicates that it is a monomethyl ether (found, 64.05%; C, 5.32% H). No Ba, Pb or Ag salt of (a) could be obtained in H_2O or alc.

CHAS. A. ROUILLER.

II. BIOLOGICAL CHEMISTRY.

WILLIAM J. GIES, EDGAR G. MILLER, JR., PAUL E. HOWE.

A. GENERAL.

FRANK P. UNDERHILL.

Enzymic adaptation. I. The saccharases. UGO LOMBROSO. *Lo sperimentale* 69, 425-45 (1915).—Defibrinated normal blood of the ox or dog possesses no hydrolyzing power upon sucrose *in vitro*. In equal time, the serum of animals treated with intravenous injections of sucrose showed a slight power of inversion. The pancreatic secretion of the dog possesses no power of inversion; this is acquired to a slight degree after injections of sucrose made subcutaneously or directly into the circulation and also after the ingestion of concd. sucrose or lactose solns. With pancreatic ext. the same results are obtained as with the secretion. An increase in hydrolyzing power, however, is not obtained by introducing sucrose into the intestinal lumen in large quantities and great concn. From the complexity of the results obtained it appears well founded that in the mechanism of modification of these enzymes it is not possible to postulate the intervention of a nervous reflex in the sense of Pawlow, Weiland and Bainbridge.

H. W. BANKS, 3d.

Enzyme of saliva which separates hydrogen sulfide from horse-radish. M. H. P. P. VAN HAEFF. *Arch. Neerland (III B)* 2, 377-84 (1915); *J. Chem. Soc.* 108, I, 914.—It was found that H_2S is produced when horse-radish is mixed with saliva, and that more is produced in a mixt. of a given wt. of horse-radish and saliva obtained by masticating, than with horse-radish finely ground with sand and mixed with saliva, indicating that the enzyme of saliva becomes adapted. The activity of the enzyme is increased by masticating horse-radish every day for a month. The enzyme, which is not identical with ptyalin, is not always present in saliva. Pure oil of mustard does not give the same action as horse-radish when mixed with saliva. E. J. C.

The mechanism of the adaptation of homotherm- to -adapted temperatures. A. MONTUORI AND R. POLLITZER. *Univ. Rome. A* 20, 344-60 (1915).
—Defibrinated blood, taken from an overheated d intravenously

or intraperitoneally into another animal of the same species maintained at a high enough temp. to produce hyperthermia, diminishes this hyperthermia and renders the animal more resistant to the temp. to which it is exposed. This effect begins to manifest itself in a very short time after the injection and reaches its max. in 30-40 min. The protective action of the supposed thermo-inhibitory substances injected diminishes gradually, when the temp. at which the animal is maintained is not excessive; otherwise hyperthermia increases rapidly. During the warm months (av. temp. 27°) the injection of defibrinated blood taken from normal animals has the same effect as blood taken from artificially overheated animals, though in less degree. Defibrinated blood from animals kept for a long time at 15° is without any effect whatever upon the injected animal.

A. W. DOX.

Chemical histology. A. B. D. FORTUYN. *Chem. Weekblad* 12, 1120-9(1915).—A report of a lecture, dealing with the importance of the chemistry of the cell and cell products in the animal tissue.

J. T. FLOHIL.

Pyrrole black. A. ANGELI. *Rend. accad. Lincei* 24, 1-6(1915); through *Ann. chim. applicata* 4, 288.—A. compares the formation of pyrrole black (by action of H_2O_2 on pyrrole in AcOH soln.) with that of the melanins. There is a marked resemblance between pyrrole black and the melanins. The latter do not show albuminoid reactions, but produce pyrrole, indole, skatole, nitriles, and pyridine. Pyrrole black by fusion with KOH or by heat, not only gives pyridine bases, but evolves vapors which give the reaction of pyrroles and of indoles, i. e., a chip of fir wood moistened with HCl turns red. H_2O_2 finally acts upon pyrrole black, which passes into soln., the liquid 1st becoming orange, and then yellow, with a light green fluorescence, suggesting the fact that the melanin of the hair loses its color by the action of H_2O_2 .

S. LEVY.

Contribution to the biochemistry of iodine. II. The distribution of iodine in plant and animal tissues. A. T. CAMERON. Univ. Manitoba. *J. Biol. Chem.* 23, 1-39(1915); cf. *C. A.* 8, 3307.—C. has made a large number of analyses using Kendall's method (*C. A.* 8, 3665) to throw further light on the distribution of I in algae, the presence of I in such tissues as the ascidian test, the annelid worm-tube and the dermis of the foot of the horse-clam and the variation in the I content of fish thyroids. The results outlined in the first paper have been verified. The I content of the thyroid of *Squalus* is remarkably const. both at different seasons of the year and from different localities. Variations in the I content of thyroid tissue can all be traced to differences in diet. In elasmobranch fish the thyroid tissue of females does not contain more I than that of males as is the case in mammals.

A. P. LOTHROP.

The influence of electrolytes upon the diffusion of potassium out of the cell and into the cell. JACQUES LOEB AND MCKERN CATTELL. Rockefeller Inst. *J. Biol. Chem.* 23, 41-66(1915).—Expts. were made on the embryo of *Fundulus* instead of the adult fish; the embryo is surrounded by a thick egg membrane through which any salt must diffuse before it reaches the embryo. The standstill of the heart and the resumption of the heart beat were taken as indicators of poisoning and recovery, resp. Eggs poisoned with KCl will not recover in distd. H_2O or saccharose soln., but will recover in a soln. of a salt or in H_2O containing a trace of acid. The relative efficiency of salts increases with the concn. of the salt and with the valency of the anion, the valency effect apparently following Hardy's rule. Eggs stained with neutral red do not lose the stain in distd. H_2O , but are readily decolorized when a trace of acid or salt is added to the H_2O . "The behavior of both the basic dye and the K can be understood on the as- their diffusion presupposes their combination with the colloidal anion. This combination is counteracted by the presence of an excess of ar- and trivalent ones, in the outside soln., and by the

presence of a trace of acid. This action of the acid may be explained on the assumption that the colloid of the membrane which binds the K and the neutral red is an amphoteric electrolyte which, through the addition of the acid is transformed into a salt, in the dissociation of which the colloid forms a cation which is no longer able to bind other cations." Poisoning with KCl is much retarded if the eggs are previously treated with distd. H_2O , the diffusion of the K being blocked by the layer of H_2O which has penetrated into the network of fibrils constituting the membrane. A. P. LOTHROP.

The role of electrolytes in the diffusion of acid into the egg of *Fundulus*. JACQUES LOEB. Rockefeller Inst. *J. Biol. Chem.* 23, 139-44(1915).—The effect of electrolytes on the diffusion of 0.002 *M* AcOH into the *Fundulus* embryo was studied. Salts inhibit the toxic action of the acid, the inhibiting action being a function of the anion as well as of the cation. Strong inhibiting action is shown by thiocyanates, acetates, sulfates and tartrates, less strong by chlorides, bromides and nitrates and little action by iodides. Ca and Sr and to a smaller degree Mg inhibit more strongly than univalent cations. As thiocyanates and tartrates are in themselves very toxic to the adult fish, the antagonistic action of the anions in these expts. consists in retarding the rate of diffusion of the acid through the membrane. It is possible that the diffusion is facilitated by the swelling effect of the acid and that the influence of the salt may be due to the antagonization of the swelling of the membrane. A. P. LOTHROP.

The apparent change of the osmotic pressure of cell contents with the osmotic pressure of the surrounding solution. JACQUES LOEB and HARDOLPH WASTENEYS. Rockefeller Inst. *J. Biol. Chem.* 23, 157-62(1915).—The osmotic pressure of the contents of fertilized and unfertilized eggs of *Fundulus* corresponds to a f. p. depression of 0.76°. If the egg is washed or kept in solns. of different concns., the osmotic pressure of the expressed juice varies somewhat with the concns. of the solns. in which it has been kept. "This is explained on the assumption that the membrane consists of fibrils and that some of the outside soln. adheres to the meshes of the outer part of the membrane, without, however, entering into the egg." The membrane is practically impermeable for H_2O and salt as long as the eggs are in physiologically balanced solns. and the outside soln. does not diffuse into the cell as the osmotic pressure of the eggs does not decrease the longer they remain in distd. H_2O . Apparently the osmotic pressure of the egg contents remains unchanged and the observed variations are due to the traces of solns. adhering in the meshes of the fibrils forming the outer part of the membrane. A. P. LOTHROP.

The total nitrogen and α -amino nitrogen content of pepsins of different strengths. T. B. ALDRICH. Detroit. *J. Biol. Chem.* 23, 339-43(1915).—Pepsins varying in proteolytic activity from 1:6,000 to 1:15,000 were analyzed for total and α -amino N. There is a gradual decrease in α -amino N in samples in the order of their strength indicating that during purification the simpler α -amino N compds. are gradually eliminated and that the stronger pepsins approach the native proteins in complexity. "The higher pepsins having a strength of 1:8,500 to 1:15,000 contain from 3.08 to 2.06% of α -amino N, equal to 13-20% of the total N, which compares with the α -amino N obtained by Van Slyke for deuto-albumose. The pepsins may therefore have been either mixtures of native proteins and their hydrolytic products, or may have consisted entirely of such products of partial hydrolysis as the lower albumoses." The % of total N shows little variation (14.14-14.94%). A. P. LOTHROP.

A study of the effects of certain electrolytes and lipid solvents upon the osmotic pressures and viscosities of lecithin suspensions. ADRIAN THOMAS. Clark Univ. *J. Biol. Chem.* 23, 359-76(1915).—The osmotic pressure of the lecithin suspension was measured with an osmometer consisting of a flask-shaped membrane of celloidin, into the neck of which was fitted a single-hole rubber stopper carrying an osmometer

tube of 3 mm. bore; the stopper was held in place by an elastic band. The membranes were suspended in small battery jars and the external medium in each case was of the same concn. of electrolyte or lipid solvent as the internal medium. Any change in pressure then was due to the effect of the electrolyte on the lecithin. The lecithin suspensions were prepared either by macerating the lecithin in warm H_2O or by dissolving it in Et_2O , adding H_2O and removing the Et_2O by warming and passing an air current through the soln. The suspensions tested contained 1% of lecithin. The osmotic pressures were decreased in the order HCl , NaI , $NaBr$, $NaCl$ and $NaOH$, the greatest depression occurring with the HCl . In general the lipid solvents increased the osmotic pressure from 15 to 33%. A Bingham-White viscosimeter (*C. A.* 6, 498) was used in measuring the viscosities. In general electrolytes lowered the viscosities but in the more concd. solns. of $NaOH$ and HCl increases were noted, due probably to direct combination with the lecithin, which is amphoteric. The lipid solvents, with one exception (isopropyl alc.), increased the viscosity. The changes observed may be regarded as due either to a mechanical or a chem. alteration of the suspensions or to both and should be considered in the theoretical explanation of anesthesia from a physico-chem. point of view.

A. P. LOTHROP.

Cephalin. II. Brain cephalin. P. A. LEVENE AND C. J. WEST. Rockefeller Inst. *J. Biol. Chem.* 24, 41-53 (1916).—Brain cephalin has been investigated to det. whether the compn. is const. and whether the amts. of the components obtained on hydrolysis agree with those required by the hypothesis that the mol. contains equimol. proportions of cephalinic acid, stearic acid, aminoethyl alc., glycerol and H_2PO_4 . The compn. was not changed by varying the nature of the solvent or the temp. at which pptn. or extn. took place. The Pb salt was prepared and gave, on analysis, values identical with the original substance. The liberation of free cephalin from the Pb salt and the reconversion of the free phosphatide thus obtained back into the Pb salt did not alter the compn. of the resulting substance. On quant. hydrolysis the sum of the components found averaged only 90% of the original wt., and it is evident that the so-called cephalin contains some other substance besides the components already mentioned. The portion unaccounted for may be an impurity. The authors are continuing the investigation of the compn. of cephalin through the prepn. and thorough purification of the hydro deriv. obtained by the reduction of cephalin with H (*cf. C. A.* 8, 713).

A. P. LOTHROP.

Experimental researches on exhaustion. G. W. CRILE. *Compt. rend. soc. biol.* 78, 52-4 (1915).—Exhaustion is that condition of the organism in which it has completely lost the power to transform potential into kinetic energy; this condition results from an alteration of one of the organs of the "kinetic system" (brain, thyroid, liver and muscles) or, as is more often the case, from simultaneous lesions of the brain, suprarenals and liver. Acute exhaustion is hastened by acute acidosis (increase in H^+ ion content of the blood), this latter condition being present after excessive muscular activity, traumatic shock, intense emotion (especially anger and fear) or anesthesia by Et_2O , $CHCl_3$, or N_2O . This acidity causes general inhibition of the motor centers, but excites the respiratory center with the result that the acidity is decreased (teleological protective measure). When the acidity of the blood too far exceeds the limits of equil., death ensues as in prolonged anesthesia.

H. S. PAINE.

Hydrolysis of albumins by the action of papain and papayotin. N. T. DELEANO. *Ann. sci. univ. Jassy* 3, 252-9; *Chem. Zentr.* 1915, II, 156.—Expts. were made to det. the hydrolysis of the ground seeds of *Lupinus luteus*. It was found that under the influence of papain the conglutin of these seeds is split into NH_3 and amino acids, the change taking place independently of the temp. Coagulated vegetable albumin is attacked with more difficulty than non-coagulated; both kinds yield the same

hydrolytic products. Coagulated or dried animal albumin is not attacked by papain. On splitting the albumin of lupine seeds by means of papain no arginine is produced; this shows that the course of the reaction is neither autolysis nor germination. Papayotin loses its enzymic activity in less time than papain. L. W. RIGGS.

Some refractories used in dentistry. GUY S. MILLBERRY. *Dental Items of Interest* 38, 49-56(1916).—A discussion of the refractory oxides, carbonates, and silicates and their properties. JOSEPH S. HEPBURN.

Explosions-in-Mines Committee VII: Effects of inhaling dusts applicable for stone dusting in mines (HALDANE) 24.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Rapid methods for the quantitative determination of albumin and sugar in urine. E. LENK. *Deut. med. Wochschr.* 41, 1281(1915).—On adding a little powdered pumice stone in the Esbach method sedimentation is completed after 10 minutes. In sugar detn. the urine is dild. and added to Fehling soln. and the end point is detd. by means of an acidulated $K_4Fe(CN)_6$ soln. S. AMBERG.

The chemical diagnosis of acute benzene intoxication. E. SCHMITZ. *Deut. med. Wochschr.* 41, 1250-1(1915).—A man died after taking, *per os*, some mixt. containing C_6H_6 . The autopsy was performed 11 days after death, the cadaver having been kept in a cool room. Three days after the autopsy the brain was examd. for C_6H_6 according to the method of Joachimoglu. The distillate obtained by heating 250 g. finely divided brain with 500 cc. water and 50 cc. 25% H_2SO_4 was caught in CCl_4 . The lower layer was nitrated. A mixt. of isomeric dinitrobenzenes was obtained and by recrystn. from 75% alc. a small amt. of nearly pure *m*-(NO_2) $_2C_6H_4$ was obtained. The mixt. of dinitrobenzenes gave the reaction of Chavassieu and Morel, that is, a transitory but intense color of violet on treating an alk. alc. soln. with reducing sugars. The color can be extd. from its watery soln. with $AmOH$ and shows an absorption band between 595 and 600 with the comparison spectroscop of Schmidt and Haensch. The amt. of C_6H_6 calcd. to be present in 1350 g. brain was 0.0745 g. But the process yields only 55-60% of the C_6H_6 . The method of Joachimoglu is well suited for the detn. of C_6H_6 in the cadaver. S. AMBERG.

Colorimetric determinations: the quantitative determination of albumin in urine. W. AUTENRIETH AND F. MINK. *Munch. med. Wochschr.* 62, 1417-20(1915).—Utilizing the biuret reaction for colorimetric comparison albumin in the urine could be detd. with about the same degree of accuracy as with the gravimetric method. Measure 10 cc. of urine, containing 1-4 per mille albumin, into a test tube. Put the tube in boiling water a few min., add dil. $AcOH$ and, if necessary, a few cc. satd. $NaCl$ soln. Collect the ppt. on a filter and wash with hot water, dissolve in 3% $NaOH$, add 4-5 drops of 20% $CuSO_4$ soln. and make up the volume to 10 cc. with 3% $NaOH$. Shake the mixt. thoroughly 2-3 min. and let stand about 10 min.; filter if necessary. The filtrate is ready for colorimetric comparison in the Autenrieth-Königsberger colorimeter against a standard which has been prepd. by comparison with albumin obtained from human urine. The compn. of the standard soln. is not given. If the urine to be tested contains more or less than 1-4% albumin less or more of it is used. S. AMBERG.

A new optical method for the detection of traces of spermatozoa. R. HELLER. *Vierteljahr. ger. Med. öffent. Sanitätsw.* 50, 37-42(1915).—The method is based on the fact that albuminous substances when subjected to ultraviolet light become fluorescent. The rays of light are filtered in practice. During the illumination cotton shows or maintains a weak bluish color, while spermatozoa give intense blue-white

rays in the dark blue background. Similar phenomena are observed even in the presence of other substances like metals, etc.

E. J. KELLEY.

Microtitration with formaldehyde and its application to physiology. I. General review of microtitration with formaldehyde. A. CLEMENTI. *Rend. accad. Lincei* 24 51-5(1915); through *Ann. chim. applicata* 4, 288-9.—C. discusses the importance of microanalysis in the biologic sciences. His purpose was to change the Schiff-Sørensen method of titration of amino acids into a micro method. Good results, differing little from theoretical values, were obtained on chem. pure solns. of glycocoll, leucine, *dl*-leucylglycinedipeptide and guanylpolypeptide. The essentials for the analysis are a 0.02 *N* soln. of NaOH, 0.001 *N* solns. of amino acids or polypeptides in CO₂-free H₂O, and burets of 1 cc. divided into 200 parts. Microtitration is practically possible, and in the case of pure solns. of amino acids, gives results conforming to theoretical. The author's results are obtained either with solns. of pure amino acids or of polypeptides. Less than 1 mg. of amino acid is sufficient to complete an analysis.

S. LEVY.

Microtitration with formaldehyde and its application to physiology. II. A. CLEMENTI. *Rend. accad. Lincei* 24, 102-7(1915); through *Ann. chim. applicata* 4, 289.—The micro-method described in the preceding abstract was applied to polypeptide enzymes, using still smaller quantities than before. Concordant results were obtained with intestinal erepsins, and with hepatic peptidases. C. proposes to apply the micro-method to the detn. of the action of arginases, for the quantitative research of amino acids in blood and in other liquids of the organism.

S. LEVY.

A new reaction for the investigation of the cerebrospinal fluid. GUSTAV EMANUEL. Charlottenberg. *Berl. klin. Wochschr.* 52, 702-4(1915).—On account of the difficulty in the prepn. and lability of the colloidal gold soln. used in the Lange test, this reaction is very much limited in its application. For this reason E. advocates the substitution of an emulsion of gum mastic for the colloidal gold soln. Neisser and Friedmann showed that it behaved in the same way. The technic for prepg. the emulsion and making the test is given. A table of results with 32 cases is given.

JULIAN H. LEWIS.

Clinical application of the Frommer-Engfeldt acetone test. N. O. ENGFELDT. Stockholm. *Berl. klin. Wochschr.* 52, 796(1915).—The technic described for the estn. of the amt. of acetone in urine is as follows: 100 cc. of the urine is dild. with an equal amt. of H₂O and acidified with 1 cc. of HOAc. The mixt. is distd. through a condenser that is well cooled and the distillate is received in a vessel kept cool and containing 20-25 cc. of cold H₂O. The distn. is carried on for 15 mins. after the first drop comes over. The distillate is dild. to 100 cc. with H₂O, 10 cc. of which is taken for analysis. To this sample 1 g. of solid KOH is added and before soln. takes place 10-12 drops of a salicylic aldehyde soln. (1 part in 10 parts abs. alc.). As the KOH goes into soln. the mixture turns from a yellow to a dark red. This color is compared with that produced by a known amt. of acetone. Cf. *C. A.* 9, 2548. J. H. L.

The measurement of toxicity. W. J. V. OSTERHOUT. Harvard Univ. *J. Biol. Chem.* 23, 67-70(1915).—In the case of a number of toxic substances, the toxicity of which is measured by their effect on the elec. cond. of living tissues, the action follows the course of a monomol. reaction and the consts. which express the reaction velocities of the two reactions afford the best measure of their relative toxicities. In cases in which such consts. cannot be used but in which a complete curve can be obtained, O. suggests the adoption, as an arbitrary standard, of the time necessary for the reaction to proceed half way to the maximum. Other criteria must sometimes be employed but it is undesirable to do so. The use of unlike criteria. The detns. should be made at 18°.

A. P. LOTHEOP.

The salicylates. II. Methods for the quantitative recovery of salicyl from urine and other body fluids. T. W. THOBURN AND PAUL J. HANZLIK. Western Reserve Univ. *J. Biol. Chem.* 23, 163-80(1915); cf. *C. A.* 10, 643.—A method is described for the detn. of salicyl (salicyl group in whatever form of combination) in urine, feces, joint fluid and blood. *Recovery from urine.* Collect the urine until salicyl-free (4-5 days) when extd. with Et_2O and tested with a 2% soln. of Fe and $(\text{NH}_4)_2\text{SO}_4$. Combine the urines into a composite sample. Measure 100 cc. of urine and 20 cc. of 85% H_3PO_4 into a 500 cc. Jena Erlenmeyer flask and boil gently while conducting steam through the mixt. Connect the flask with a condenser by means of a distg. bulb and conduct the distillate into a graduated flask. Continue the distn. over a gentle flame until the concd. residue begins to foam. Add more H_2O and continue the distn. until 2 drops of the distillate give no pink color with 2 drops of Fe and $(\text{NH}_4)_2\text{SO}_4$. Distil 25 cc. after the test becomes negative. The distillate should be perfectly clear, practically colorless and possess a neutral or very slightly acid reaction to litmus. Dilute with distd. H_2O to a definite vol. Prepare a standard by dissolving 0.115 g. of dry Na salicylate in 1 l. of distd. H_2O ; 1 cc. = 0.1 mg. of salicylic acid (the soln. remains unchanged for about a week). Add to a definite vol. (5-10 cc.) of the distillate 0.1-0.5 cc. of the 2% Fe and $(\text{NH}_4)_2\text{SO}_4$ soln., dil. to 50 cc. and compare the pink to violet color with that produced by a definite quantity of the standard dild. to 50 cc. and containing an equal amt. of the Fe soln. until the colors match. Make a rough trial at first and repeat the detn. at least twice to get the exact quantities of distillate and standard which match. Compare the colors in standard Nessler tubes as these give more accurate results than the small Duboscq colorimeter cups. Less than 0.02 mg. and more than 5 mg. cannot be detd. *Recovery from joint fluid and blood.* Dil. 15 cc. of blood or fluid with 98% EtOH to 150 cc. and shake vigorously. Allow to stand 1 hr. and filter. Transfer 100 cc. of the filtrate to a beaker and add 5-6 drops of a satd. ZnCl_2 soln. Boil gently on an elec. stove until most of the EtOH is removed. Add 25 cc. of distd. H_2O and conc. to $1/2$ by boiling. Filter and wash the paper with hot H_2O (3-4 times) until salicyl-free. The filtrate should be refiltered if not clear. Add a little H_2O and 20 cc. of H_3PO_4 , distil and estimate the salicyl in the distillate as described under urine. 95% of the salicyl in blood is removed by this procedure. *Recovery from feces.* Recovery from feces is unimportant for all practical biological purposes owing to the presence of only extremely small amts. due to rapid absorption. A method of procedure is outlined. *Recovery of free salicylic acid from blood and joint fluid.* Ext. an aliquot portion (25-100 cc.) or the entire quantity of unclotted blood or fluid with small amts. of Et_2O (15-25 cc.) by gently rotating the separatory funnel, until 2-3 drops of the Et_2O ext. evapd. on a watch glass give no color with a drop of the Fe and $(\text{NH}_4)_2\text{SO}_4$ soln. Place the Et_2O exts. in a glass evapg. dish and allow the Et_2O to evap. spontaneously. Treat the residue with hot distd. H_2O until dissolved and rub down the sides of the dish. Filter and wash the paper until the washings give no color with the Fe soln. Make up the filtrate to a definite vol. (50 cc.) and est. as directed under urine. The residual portion from the separatory funnel may be analyzed for combined salicyl as described under blood if the material is limited.

A. P. LOTNROP.

An effective apparatus for evaporating aqueous extracts by means of a current of air. T. B. ALDRICH. Detroit. *J. Biol. Chem.* 23, 255-9(1915).—An app. is described for evapg. large vols. of liquids, containing substances not sensitive to oxidation but sensitive to heat, by means of a warm blast of air. Using 2 flat dishes having a combined surface area of 180 sq. in., a liter of liquid can be evapd. in about 3 hr. at 28-30° at a cost of about 4 cents.

A. P. LOTNROP.

The determination of ammonia nitrogen in
Penn. State College. *J. Biol. Chem.* 23, 311-

C. COCHRAN
of $(\text{NH}_4)_2\text{CO}_3$

makes the figures for N as free NH_3 unreliable and those for total ammonia N are worthless unless the rapid NH_3 decompn. is prevented. CHCl_3 and toluene are ineffective in preventing decompn. H_2SO_4 in slight excess of the amt. sufficient to fix the NH_3 present as carbonate retards decompn. to such an extent as to allow time for analysis. All NH_3 detns. must be made on daily samples because H_2SO_4 does not completely stop decompn. in a composite sample. The results cast doubt on the accuracy of NH_3 detns. in the urine of herbivora reported in the literature. The N as NH_3 compds. was detd. by Steel's modification of Folin's method (*C. A.* 5, 302) on account of the large amt. of phosphates in steer urine. A. P. LOTHROP.

The Abderhalden reaction. DONALD D. VAN SLYKE, MARIAM VINOGRAD-VILCHUR AND J. R. LOSER. Rockefeller Inst. *J. Biol. Chem.* 23, 377-406(1915).—A simple and quant. method has been devised for measuring by amino-N detn. the extent of the proteolysis occurring when substrate and serum are incubated as in the Abderhalden reaction. The method is sufficiently simple, accurate, free from subjective influence and specific for proteolysis to afford definite conclusions concerning the facts of the reaction. Extreme care was taken in the prepn. of the placenta substrate, the precautions prescribed by Abderhalden being strictly observed. Colloidal $\text{Fe}(\text{OH})_3$ was used to free the mixt. from protein after incubation, and, after evapn., the free amino-N in the filtrate was detd. with the micro-amino app. Only normal sera were used as controls. "Practically every serum, whether from pregnant or a non-pregnant individual, showed protein digestion when incubated with placenta tissue. The range of individual variation in proteolytic activity was wide. The range covered by most of the normal sera was, however, identical with that covered by the majority of the pregnant sera. There is a tendency for the results from the pregnant sera to average somewhat higher than those from non-pregnant. The difference, even in the averages, is not great, however; and the individual variations of both pregnant and non-pregnant sera make the results from both overlap so completely as to render the reaction, even with quant. technic, absolutely indecisive for either positive or negative diagnosis of pregnancy. Further evidence of non-specificity is seen in the fact that carcinoma tissue was digested to about the same extent as was placenta. It appears that nearly all human sera can digest certain coagulated tissue proteins to some extent, but that the source and significance of the proteolytic agents, and the influences that cause their fluctuation remain as yet undetd." A. P. LOTHROP.

The micro-method for gasometric determination of aliphatic amino nitrogen. DONALD D. VAN SLYKE. Rockefeller Inst. *J. Biol. Chem.* 23, 407-9(1915).—A modified gas buret has been devised which increases the accuracy of the readings to such an extent that only 1 cc. of soln. is required for analysis with consequent reduction of the amt. of material required to obtain results of the same % accuracy. Soft, flexible "stethoscope" tubing which has a wall 3-4 mm. thick is best adapted for the rubber connections. A. P. LOTHROP.

Analysis of proteins by determination of the chemical groups characteristic of the different amino acids. DONALD D. VAN SLYKE. Rockefeller Inst. *J. Biol. Chem.* 23, 411(1915).—The formula for calcg. histidine in the original article (*J. Biol. Chem.* 10, 29) is incorrect. It should read: Histidine N = 1.5 D.—1.125 Arg. A. P. L.

Can carbon dioxide in sea water be directly determined by titration? S. MORGULIS AND E. W. FULLER. U. S. Fisheries Biol. Station, Woods Hole. *J. Biol. Chem.* 24, 31-5(1916).—M. and W. criticize the conclusions of Moore, *et al.* (*C. A.* 7, 523) regarding the method of detg. CO_2 in marine organisms. In their expts. on several species of fish, respiratory CO_2 was obtained as compared with 0.95-2.76 as reported by Moore. When known quantities of CO_2 are added to alkali with phenol.

H₂O, on an average not more than 33% can be recovered by titration and with sea water factors, such as amt. of indicator, excessive agitation, etc., cause appreciable differences in the titration. "No results obtained by a method of such questionable value are of importance nor can general conclusions derived from them receive serious consideration."

A. P. LOTHROP.

Detection of alcohol in cadavers. M. CARRARA. Turin. *Liguria med.* 7, 187; *Zentr. Biochem. Biophys.* 18, 130(1915).—The Nicloux method of detection of alc. in the cerebrospinal fluid was used for the purpose of throwing light on the question of whether death was caused by accident or by excessive intoxication. This method (which depends on the production of the green coloration of Cr₂(SO₄)₃) gave satisfactory results.

H. S. PAINE.

Investigation of milk with relation to legal medicine. A. CEVIDALLI AND E. MURGIA. Cagliari. *Liguria med.* 7, 198; *Zentr. Biochem. Biophys.* 18, 115(1915).—These investigations relate to the detection of milk spots. The milk spots should be dissolved in H₂O and the milk globules should be stained scarlet-red with Sudan III. Maceration of short duration in 10% soda soln. may occasionally be necessary, but this should be followed immediately by washing with distd. H₂O. Detection of colostrum corpuscles may be accomplished by the same method. The Tugendreich reaction (which is adapted to microscopic observation) is recommended for sp. diagnosis.

H. S. PAINE.

Determination of the reaction of urine. H. F. HÖST. Christiania. *Z. klin. Med.* 81, 266-71(1915); *Zentr. Biochem. Biophys.* 18, 119(1915).—The Friedenthal and Salm colorimetric method (more thoroughly studied by Sørensen) is recommended for the detn. of the reaction of the urine. The principle employed depends upon a comparison of the color of the urine in question with that of solns. of various definite H⁺ concns. after the addition of an indicator. Sørensen's phosphate and borate mixts. and Michaelis' NH₄Cl-NH₄OH solns. are used as reagents. The "primary" phosphate is a 0.2 M soln. which contains 9.078 g. KH₂PO₄ per l., while the "secondary" phosphate is a 0.2 M soln. with 11.876 g. Na₂HPO₄ per l. NHCl, NH₄Cl and NH₄OH solns. are also used. The indicators are methyl red (satd. soln. in 50% alc.), neutral red (0.1% soln. in 50% alc.) and phenolphthalein (1% soln. in 96% alc.). The temp. employed throughout is 18°. The phosphate and borate mixts. are first prepd. and brought to the color of the urine with Bismarck-brown; color comparison is then made after addition of the indicators. Good results were obtained with the method, which is not complicated and may be operated with relative rapidity in the examn. of numerous samples of urine.

H. S. PAINE.

Acetone in milk. N. O. ENGFELDT. *Svensk Farm. Tidskrift* 19, 610-20(1915).—100 cc. of the sample of milk are mixed with 260 cc. water and 40 cc. 10% tannic acid added to remove the proteins. After filtering and washing, the filtrate is distd. just 15 min. and the acetone in the distillate detd. by 2 methods. These methods are the well known iodometric titration and a colorimetric method described in C. A. 9, 2100, 2548. The samples were tested for phenols, reducing substances, nitrates and nitrites, which interfere with the former method. Reducing substances develop in the milk on standing. This can be largely prevented by adding boric acid to the sample. Where the detn. was to be made some time after the drawing of the milk the distillate was treated with KOH and H₂O₂ and redistd. In the second distn. the heat is raised to boiling very slowly, to complete the oxidation. The amt. of acetone in the milk seems to vary with the yield but not with the time of milking, period of lactation, nor the age of the animal. The colostrum has an acetone content within the same range as that of normal milk. Human milk contains from 0.48 to 1.16 mg. acetone per liter.

that of the cow from 1.45 to 2.42 mg. and that of sheep and goats from 0.48 to 1.45 mg. per liter.

A. R. ROSE.

Characterization of picric acid in urine. P. GRÉLOT. *J. pharm. chim.* 12, 209-15 (1915).—The direct test for picric acid in neutralized urine by means of KCN soln. is uncertain, also when KCN is applied to the Et_2O ext., owing to presence of picramic acid, or of uroerythrin. The wool test is reliable, and is not interfered with by biliary pigments or pathological coloring matter of the urine. Defecate 100 cc. of urine with 0.1 of its vol. of $\text{Pb}(\text{OAc})_2$, filter, remove Pb by H_2SO_4 , again filter, ext. the liquid with 0.2 of its vol. of Et_2O and sep. The yellow Et_2O soln. containing picric and picramic acids stains wool more or less orange, permanent towards soap. Its change to red by means of $(\text{NH}_4)_2\text{S}$ is not a very sharp test. Check tests may be carried out with the Et_2O residue, either by transforming picramic into picric acid by means of HNO_3 or H_2SO_4 , or by reducing these acids to $\text{C}_6\text{H}_5(\text{OH})(\text{NH}_2)_2$ by means of Sn in HCl soln. The HCl soln. dild. with 10-20 vols. of H_2O turns blue, then lilac, then colorless upon exposure to air, or more rapidly by the addition of 1-2 drops of FeCl_3 soln. (1:10).

S. WALDBOTT.

Detection of iodine in urine. LOSSER. *Pharmazeutisches Journal* 54, 265 (1915); *J. pharm. chim.* 12, 229-30 (1915).—A few drops of urine are well mixed on a watch crystal with a particle of HgCl_2 . After a few seconds, a distinct yellow color develops, due to HgI_2 . The reaction is sensitive to as little as 0.01% of I. The presence of sugar or albumin does not disturb.

S. WALDBOTT.

Apparatus for the determination of urea and sugar in urine. RICHARD WEISS. *Schweiz. Apoth. Ztg.* 53, 646, 689-90 (1915).—From the vol. of N produced with NaBrO , or of CO_2 with yeast, the % of urea, or of sugar, may be read from the instrument. The gas is generated in a small wide-mouthed bottle and, if CO_2 , displaces glycerol; if N it displaces H_2O in a graduated cylinder open at the bottom and closed on top by a pinch cock. The cylinder is surrounded by a wider glass into which the measuring liquid is put. By opening the pinch cock, the liquid is brought to the zero mark. In the case of urea, a definite vol. of dild. urine is put into the bottle, and the NaBrO soln., placed into a small cup within the bottle, is kept sepd. from the urine until zero adjustment in the cylinder is made; then the cup is upset by shaking.

S. W.

Quantitative method for the determination of pus in urine of "pyelitic" children by means of hydrogen peroxide. A. NORGAARD. Copenhagen. *Z. Kinderheilk.* 13, 244-7 (1915).—The pus cell contains a catalase, which decomps. H_2O_2 . The amt. of this decompn. produced by a urine is taken as a measure of the pus content. The time of the reaction is about 3 hrs.

was completely liquefied by the 8th day. The bacillus is aerobic and its optimum temp. of growth is 28–35°. Subcutaneous inoculation of guinea pigs and rabbits with this bacillus resulted in putrid abscesses with symptoms of general intoxication; the same effects, with more rapid occurrence, were produced by intravenous injections. This organism is considered to be a new form of pyogenic bacillus. H. S. PAINE.

The relation between vegetative vigor and reproduction in some Saprolegniaceae. A. J. PIETERS. *Am. J. Botany* 2, 529–77(1915).—With several species of Saprolegniaceae no necessary relation exists between the vegetative growth and the reproductive capacity. Expts. with *Achlya racemosa*, *A. prolifera*, *Saprolegnia ferax* and *S. monoica* all agree in showing that a mycelium out of a relatively poor soln., measured by vegetative growth, may produce more or larger oogonia than are produced on a mycelium from a soln. that is much better for vegetative growth. Levulose is used more readily by *Saprolegnia ferax* and *S. monoica* than other sugars except maltose, and it has a greater effect in developing the production of oogonia than maltose has. Sucrose is probably not used by species of *Saprolegnia* or of *Achlya* unless it is first inverted by some other agency. P in the culture soln. tends to increase the reproductive capacity of the fungus. The minimum concn. of food necessary varies with the species but lies in general at about 0.1% peptone for the production of both sporangia and oogonia. While growing vegetatively a mycelium may develop tendencies that may affect the number and character of reproductive organs under subsequent and different conditions. J. J. SKINNER.

Bákhar: The Indian rice beer ferment. C. M. HUTCHINSON AND C. S. RAM-AYYAR. *Mem. Dept. Agri. India (Bact. Ser.)* 1, 137–68(1915).—This investigation was conducted to ascertain whether the manufacture of bákhar, an artificially prepd. ferment, can be advantageously controlled by the government, and if so, in what manner. The kind of microorganisms and their relative physiological activities, with reference to their saccharifying power and alc. production, in the various samples of bákhar were detd. The expts. show that variations in quality of bákhar accompanied by fermentation failures are not so much to be attributed to absence of efficient amyliferments as to that of good types of *Saccharomyces*. Better results were obtained when the diastase secreted by *Aspergillus* was destroyed by heating before the addition of yeast, the action of which is seriously interfered with by the presence of any considerable amount of this enzyme in the sugar soln. to be fermented. The activity of the yeast is also increased by aeration of the liquid. J. J. SKINNER.

Possible sterilizing properties of dental cements. W. V.-B. AMES. *J. Ind. Eng. Chem.* 7, 723(1915).—Polemical. Answer to the criticism of Poetschke (*C. A.* 9, 3289). E. J. C.

The germicidal efficiency of some copper cements used in dental work. RAYMOND F. BACON. Univ. Pittsburg. *Dental Cosmos* 58, 40–9(1916).—The germicidal efficiency of Cu cements is due to the fact that they constantly give off minute traces of Cu, which pass into soln. and kill the organisms. A cement is satisfactory if it kills all the bacteria in a reasonable time, and exerts a sterilizing action as long as it remains in the tooth, preventing the development of bacteria in contact with the cement. Four commercial cements (a Cu cement, Cu oxyphosphate cement, and 2 brands of white Cu cement) were examined and found to satisfy these requirements. Dentine from badly decayed teeth was crushed and added to saliva from the mouth of a person with well preserved teeth; the mixt. was then filtered, there being obtained a filtrate a culture which contained both the normal and the abnormal oral flora as met in dental surgery. The cements were tested as hardened pellets of uniform size and shape. Ten pellets of a given cement and 5 cc. of the prepared saliva were incubated at 37.5°;

tube (bouillon) and plate (agar) cultures were made at intervals. The saliva invariably became sterile after the cement had acted on it for 6 hrs. JOSEPH S. HEPBURN.

Influence of the pyrrole nucleus upon the formation of chlorophyll. G. POLLACCI AND B. ODDO. *Rend. accad. Lincei* 24, 37-9(1915); through *Ann. chim. applicata* 4, 288.—Mg pyrrole carbonate has a harmful action upon *Zea mays*, at concns. above 50% in aq. soln.; in plants sprung from seeds sprouted in aq. soln. of Mg pyrrole carbonate of less than 0.5% strength, the tissues were found to be normal. Care was taken that this salt as well as the H₂O be free of Fe. According to the authors, the formation of chlorophyll in plants grown in Fe-free soil is a new observation.

S. LEVY.

A pathological and physiological study of the black heart of the potato tuber. E. T. BARTHOLOMEW. Madison, Wis. *Centr. Bakt. Parasitenk., Abt. II* 43, 609-41 (1915).—Shippers in various parts of the U. S. have suffered considerable loss in their shipments of potatoes in carload lots due to an internal blackening of the potatoes. This paper is a report of an investigation into the cause of this condition. It is found that the black heart is produced by abnormal physiological changes and not by a parasitic organism. The abnormalities may be produced artificially by subjecting the potatoes to a temp. of 38-48°, 42-4° being the optimum. The optimum length of time of exposure is 15-20 hrs. Sixteen varieties of potatoes were experimented with and since all these responded to the test, it is assumed that all other varieties will behave in a similar manner. By supplying sufficient O during the heating period the abnormality may be prevented. The demand for O during this period is greater than before and can be supplied by bathing the potatoes with a constant stream of air. If after removing from the oven, the potatoes are kept in an atm. devoid of O, the tissues will not blacken. Usually the abnormality cannot be detected before the potato is cut open. If the affected tubers are allowed to remain a wk. or 10 days before cutting open, a hollow is formed in the interior, due to the shrinking of the abnormal tissues. An oxidizing enzyme (tyrosinase) and a chromogen (tyrosine), which readily interact in the presence of free O, are present in both normal and abnormal tissues. As a result of the interaction of these 2 substances, the affected tissues undergo a series of color changes which range from light pink to coal black. The increase in amt. of the chromogen present in free form, the access of an unusual amt. of free O₂ due to the killing of the cells, and the accelerated action of the oxidizing enzyme, all work together to make possible the rapid discoloration of the tissues. Tests for homogentisic acid in the abnormal tissues were negative. The amino acid content of the potato tissues during the heating period was greatly increased. The substance causing the discoloration of the abnormal tissues is melanin or humin. From these expts. it is concluded that the formation of black heart potatoes can be prevented in shipping by proper ventilation and by keeping the potatoes in a temp. which does not exceed 35°.

JULIAN H. LEWIS.

The action of illuminating gas on plants. P. SORAUER. *Landw. Jahrb.* 48, 137-69(1915); *Chem. Zentr.* 1915, II, 715.—The results of S.'s expts. to det. the influence of illuminating gas on vegetation, are summed up as follows: The blue coloration of the roots can be looked upon only as a usual and not as an invariable symptom of illuminating-gas poisoning since this coloration also occurs during the decay of dead roots. As a result of the exclusion of O from the roots in a soil satd. with gas, intramol. respiration takes place at the expense of the cell contents. The reserve starch of the roots disappears and, as a rule, the entire cell content of the root rind. During slower action of illuminating gas upon the roots, the resulting intramolecular respiration also

manifests itself in the upper parts of the plant; the chlorophyll is disturbed, etc. With the drying of the green parts of the plant and the decrease in evapn., a consequent excess of H_2O accumulates in the lower parts. Finally attention is called to a mucid obstruction of the fleshy roots which with the exception of O exclusion was only found accompanying the action of illuminating gas. These symptoms together with the quick withering of cut twigs placed in water, when taken as a whole, are characteristic of illuminating-gas poisoning.

C. F. MILLER.

Phenomena of slow combustion in dead plants. M. P. MAZÉ. *Compt. rend. soc. biol.* 78, 30-2(1915).—Expts. in which precautions were taken to exclude fermentation, etc., showed that slow combustion in dead plants is characterized by values of the coeff. CO_2/O_2 which are widely different from those furnished by the respiration of living plants; it is, therefore, concluded that the slow combustion which ensues in dead plant material is not analogous in its nature to respiratory combustion. Plant tissues possess a structure and compn. which, after the death of the plant, favor a form of slow combustion, the external indications of which have some points in common with those of respiration.

H. S. PAINÉ.

Experiments on the physiology of indigo-yielding glucosides. F. R. PARNELL. *Mem. Dept. Agr. India (Botanical Ser.)* 7, 195-212(1915).—An indigo-yielding glucoside is present in the roots and seeds of both *W. tinctoria* and *W. tomentosa*. It is absent from the leaves of the latter. The glucoside and its enzyme in *W. tinctoria* are distinct from those of *Indigofera arrecta* and *I. sumatrana* although *Wrightia* enzymes have some action on *Indigofera* glucoside and *vice versa*. *W. tinctoria* seeds, when germinated and grown without N, increase in glucoside content until it becomes about trebled in 40 days. When N starvation begins to show, the amount decreases, but is still considerable when the seedlings are on the point of death. *W. tomentosa* seedlings show no appreciable increase of glucoside under the same conditions. When cuttings of *Polygonum tinctorium* and *Strobilanthes flaccidifolius* are grown without N, part of the glucoside disappears, presumably being used up as a N reserve. In *W. tinctoria* and *I. Arrecta*, the max. % content occurs at an early stage in the development of the leaf. The actual amt. in any leaf increases during growth to a max. at maturity and remains constant until leaf-falls, when the whole is present in the fallen leaf. Indican is produced in the dark by etiolated shoots of *I. Arrecta*. There is no variation in indican content between night and day in *I. Arrecta* and *I. sumatrana*.

E. NUTRITION.

PHILIP B. HAWK.

NORMAL.

Digestibility of some animal fats. C. F. LANGWORTHY AND A. D. HOLMES. Office of Home Economics. U. S. Dept. Agr., *Bull.* 310(1915).—The digestibility of butter and of rendered kidney fat of beef, mutton and pork was studied. The basal diet consisted of wheat biscuit, fruit, tea or coffee with a little sugar if desired; to this was added a blanc mange containing skim milk, caramel, sugar, corn starch, vanilla flavor, and the fat whose digestibility was to be tested. The av. quantity of fat consumed daily by each subject varied with the kind and was: pork fat 90, beef fat 100, mutton fat 53, butter fat 100 g. Each experimental period included 3 days, and was followed by a rest period. The subjects were men students between 20 and 30 yrs. of age. Several subjects were studied with each fat. The ingested fat and the feces fat were detd.; the difference was digested fat. The av. per cent digested was: pork fat 93.7, beef fat 88.9, mutton fat 80.5, butter fat 93.9. To allow for fecal metabolic fat, the basal ration plus blanc mange, to which no fat had been added, was fed; ingested and fecal fat were detd.; and the quantity of metabolic products in the ether

ext. of the feces was calcd. The coeffs. of digestibility were then found to be: butter fat 97, pork fat 97, beef fat 93, mutton fat 88%. The m. p. was detd.: butter fat 32.0°, pork fat 35.0°, beef fat 45.0°, mutton fat 50.0°. "It seems fair to conclude that of those tested the fats of low m. p. are capable of more complete assimilation than those which have a high m. p." A laxative effect was noted when 140 g. of beef fat were eaten in 1 day.

JOSEPH S. HEPBURN.

The metabolic relationship of the proteins to glucose. III. Glucose formation from human proteins. N. W. JANNEY AND N. R. BLATHERWICK. Montefiore Home, N. Y. *J. Biol. Chem.* 23, 77-80(1915).—Human muscle was fed to fasting phlorizinized dogs and the sugar formed from the proteins contained in the muscle was calcd. In 5 expts. an av. of 58% of the muscle protein was converted into glucose and a "ratio of 3.6:1 may be accepted as representing the relation between the N contained in human muscle protein and the glucose originating from the same in metabolism. The proteins of the human organism collectively may yield a max. of about 58% of glucose in diabetic metabolism. In the fasting human diabetic of the severest type, when glycogen and possible sources of glucose other than protein are exhausted, the urinary G:N ratio 3.4:1 may be accepted as an av. value." Higher ratios recorded in the literature can no longer be accepted.

A. P. LOTHROP.

The effect of ingested purines on the uric acid content of the blood. W. DENIS. Harvard Med. School. *J. Biol. Chem.* 23, 147-56(1915).—The subjects used in the expts. were adult hospital patients and were divided into three classes: "normal individuals" who were normal except for surgical conditions; nephritic and cardiorenal cases; and persons suffering from chronic diseases not associated with kidney insufficiency or fever. The purine-free diet consisted of eggs, bread, milk, cheese, butter and fruit and during the high-purine feeding the eggs and most of the bread were replaced by a daily ration of 150 g. of calves' liver, 200 g. of roast beef or chicken and 200 cc. of "concd. broth" (hospital soup boiled down to $\frac{1}{4}$ its original vol.). Detns. of uric acid and non-protein N in the blood were made at the end of each period, and uric acid in the urine was detd. daily. In the normal individuals the ingestion of large amts. of purine-containing food did not increase the uric acid content of the blood, the normal kidney excreting the excess of uric acid thereby maintaining the amt. of circulating uric acid at the same level as when only endogenous uric acid is to be excreted. A more or less marked increase in uric acid was observed in the blood in cases of renal insufficiency, even when the damage to the kidney had not progressed to the point where N retention was apparent. "When the detn. of uric acid in the blood is undertaken as a diagnostic test, the insistence on a preliminary period during which no purine-containing foods are consumed is unnecessary, except in cases in which kidney insufficiency exists, or perhaps in the case of persons who habitually consume extremely large quantities of purine-containing foods."

A. P. LOTHROP.

The nature of the dietary deficiencies of rice. E. V. MCCOLLUM AND MARGUERITE DAVIS. Univ. Wisconsin. *J. Biol. Chem.* 23, 181-230(1915).—"There are necessary for normal nutrition during growth 2 classes of unknown accessory substances, one sol. in fats and accompanying these in the process of isolation of fats from certain foodstuffs, and the other sol. in H_2O (and alc.), but apparently not in fats." The H_2O and alc.-sol. accessory is present in H_2O and alc. exts. of wheat embryo and of egg yolk; it is stable to heat and is not injured to any noticeable degree by prolonged boiling. The amts. of H_2O ext., freed from protein by coagulation, which supply enough of the H_2O -sol. accessory to induce normal growth, contain N equiv. to about 1% of the total N of the ration and amts. of alc. ext. of wheat embryo containing only 0.6 g. of solids and N equiv. to 0.33% of the total N of the ration suffice to induce normal growth. The H_2O -sol. accessory is not identical with that furnished by butter

fat for the addition of as much as 20% of butter fat does not induce growth unless the other accessory is supplied. "Purified proteins, fats having the growth-promoting property, and salt mixts. of appropriate compn. cannot adequately supplement polished rice so as to produce a diet which will support growth." The deficient mineral salt content of the polished rice is not the cause of the deficiency as the addition of salts and free mineral acids closely imitating the inorganic content of the polished rice to rations of milk powder and dextrin and of dried egg and dextrin does not cause any loss of growth-promoting power. Mixts. of rice and egg, rice and milk powder, and rice and wheat embryo containing as much as 80-90% of rice are satisfactory for growth and prolonged well-being, indicating that polished rice is in no way toxic to animals. Enough of the H_2O -sol. accessory which is essential to induce growth is furnished by the addition of amts. of wheat embryo or milk powder as small as 2% of a ration consisting of polished rice, casein, salts and butter fat. On the other hand the fat-sol. accessory must also be supplied as no growth occurs on the above diet if the butter fat is eliminated. Rice does not contain much, if any, of the fat-sol. accessory, but rice polishings carry the H_2O -sol. accessory.

A. P. LOTHROP.

The essential factors in the diet during growth. E. V. McCOLLUM AND MARGUERITE DAVIS. Univ. Wisconsin. *J. Biol. Chem.* 23, 231-46(1915).—The employment of lactose and casein of relatively high purity in rations made up of food-stuffs otherwise carefully purified is open to serious objection and their use in such rations has led to erroneous conclusions, since they must be of exceptional purity to be free from both the H_2O -sol. and fat-sol. accessories (cf. preceding abstract). The authors have purified casein after 2 reprecipitations by washing in H_2O acidified with $AcOH$ for 6-7 days and with distd. H_2O for 24 hrs. The product was very poor in ash and all the H_2O -sol. constituents were dialyzed out of the granules. With this specially purified casein combined with dextrin, butter fat and salts no appreciable growth in rats was obtained, even during the first month. In a study of the relative values of isolated proteins fed with mixts. of purified food substances, comparable amts. of these 2 classes must be supplied. Otherwise no safe interpretations can be put upon the results. While the amt. of accessory substances of either of these classes which is required to induce growth is small, the evidence points to the belief that a certain quantity must be present before any growth can take place, and that above this amt., growth seems to be in some measure proportional to the amt. of accessories present. A. P. L.

The cause of the loss of nutritive efficiency of heated milk. E. V. McCOLLUM AND MARGUERITE DAVIS. Univ. Wisconsin. *J. Biol. Chem.* 23, 247-54(1915).—Moist skim-milk powder that has been heated for a long time in a double boiler, or for 1 hr. in an autoclave at 15 lbs. pressure, no longer supports growth, and loses its property of supplanting rations which require both protein and H_2O -sol. accessory to make them support growth. Wheat embryo can be heated under the same conditions without losing this property. Whey and lactose can be heated in an autoclave for 1 hr., and whey from which the albumin has been removed by coagulation, can be kept at the boiling temp. for 6 hrs. and still supply the H_2O -sol. accessory in active form. Heating moist casein for 1 hr. in an autoclave destroys its biological value as a complete protein, and the loss of nutritive efficiency of heated milk is due to a loss of value of the protein fraction of the ration through changes in the casein. Heated casein or milk powder have little, if any, toxicity.

A. P. LOTHROP.

Xanthophyll, the principal natural yellow pigment of the egg yolk, body fat, and blood serum of the hen. The physiological relation of the pigment to the xanthophyll of plants. LEROY S. PALMER. Univ. Missouri. *J. Biol. Chem.* 23, 261-79(1915).—The hen utilizes relatively little carotin in the pigmentation of the egg yolk and body fat, the principal pigment belonging to the xanthophyll group of plant pigments. The

natural pigment of the egg yolk, body fat and blood serum, is physiologically identical with the carotin and xanthophyll pigments of plants, but the latter class is present in by far the greater proportion. "Feeding tests with laying hens, in which the pigment of the feed was carotin to the relative exclusion of xanthophyll, were without appreciable influence upon the amt. of pigment carried by the blood serum and deposited in the egg yolk. The feeding of rations relatively free from both carotin and xanthophyll to laying hens resulted in a marked reduction of the amt. of this pigment." The color of the flesh of fattening poultry and the amt. of natural pigment in the egg yolk can be controlled by selecting rations containing little xanthophyll in the first case, and feeds rich in that pigment when yellow yolks are desired. A. P. L.

The behavior of some hydantoin derivatives in metabolism. III. Parabanic acid. HOWARD B. LEWIS. Univ. Penn. *J. Biol. Chem.* 23, 281-6(1915).—Parabanic acid was fed to rabbits and to a dog, and the urine was analyzed for total N and for urea by the urease method of Van Slyke and Cullen. No evidence of the conversion of significant amts. of parabanic acid into urea was obtained in any of the expts. The increase in total N corresponded closely to the amt. of N administered as parabanic acid. In the dog the ingestion of the acid caused a stimulation of metabolism. In 2 perfusion expts. in which parabanic acid was added to blood which was perfused through the livers of a normal and of a phlorizinized dog, there was no destruction of the parabanic acid by the liver. A. P. LOTHEROP.

Experiments upon the fate of ingested sodium nucleate in the human subject. MAURICE H. GIVENS AND ANDREW HUNTER. Cornell Univ. Med. College. *J. Biol. Chem.* 23, 299-309(1915).—Na nucleate was ingested in 4 expts. after equil. had been established on a diet practically purine-free. In each case the administration of the nucleate was without effect on the purine bases of the urine. Only from 14 to 30% of the Na nucleate could be accounted for by the increase in uric acid excretion. In 2 cases there was a marked delay (3-4 days) in the elimination of the exogenous uric acid and it is evident that its elimination may normally take place much less promptly than is usually supposed. G. and H. are inclined to accept the view of Siven (*C. A.* 8, 2741) that "purines entering, or liberated in, the alimentary canal undergo, before absorption, a varying degree of bacterial destruction." A. P. LOTHEROP.

Studies on blood fat. II. Fat absorption and the blood lipoids. W. R. BLOOR. Harvard Med. School. *J. Biol. Chem.* 23, 317-26(1915).—Dogs which had fasted for 24 hrs. were given a feeding of fat and the blood lipoids were detd. in samples of blood drawn from the jugular vein at intervals over a period of about 8 hrs. The blood was analyzed for (a) total fat (fatty acid + cholesterol), (b) cholesterol and (c) lecithin. The fatty acids show the ordinary increase of alimentary lipemia but the increases vary in different animals and in the same animal at different periods. Cholesterol plays at most a minor part in fat absorption as in general there is only very slight variation in the amt. present. Lecithin increased in all the expts. from 10 to 35% with an av. of about 20%. "It is possible that the extra lecithin may represent that part of the absorbed fat which is intended for immediate use and which has been synthesized for that purpose from the material absorbed from the intestine." This synthesis may take place in the liver by the passage of the 30-40% of fat, which cannot be accounted for in the thoracic duct, through the intestinal capillaries and portal circulation to the liver, thus providing abundant material for the formation of the lecithin. On the other hand, the lecithin may be synthesized in the intestinal wall, just as the fatty acids and glycerol are converted into glycerides. "However, if fats and lecithin were formed simultaneously, the parallelism between the two in the blood would be more apparent." "The increases in lecithin come later and more gradually than the increases in fat, and the fat, in the blood, is the more abundant." "The increases in lecithin come later and more gradually than the increases in fat, and the fat, in the blood, is the more abundant."

crease in fat in the blood is the stimulus which starts the lecithin formation and that the intestine is not the seat of formation." A. P. LOTHROP.

Some features of purine metabolism. H. GIDRON WELLS. Univ. Chicago. *J. Lab. Clin. Med.* 1, 165-71 (1915).—Review of the literature, especially with reference to the work from the author's lab. H. G. W.

The influence of calcium supply on propagation. R. EMMERICH AND O. LOEW. *Landw. Jahrb.* 48, 313-30 (1915); *Chem. Zentr.* 1915, II, 717.—Expts. carried out with mice, rabbits and guinea pigs led to the following conclusions: A greater Ca supply increases the number of litters; the number of young is greater when their individual weight is less. CaCl_2 is more effective than KCl or MgCl_2 . NaCl was found to have a favorable action. The increased production brought about by NaCl results in a large decrease (12%) in the wt. of the mother animals (mice). C. F. M.

F. PHYSIOLOGY.

ANDREW HUNTER.

The coagulating power in vitro of the tissues most commonly used in hemostatic dressings. L. TORRACA. *Lo sperimentale* 69, 493 (1915).—In studying the coagulating power of the tissue exts., the method of Bürker (*Arch. ges. Physiol.* 149 (1912)) was followed. Exts. of aponeurotic, adipose, muscular, and epiploic tissues all possessed a certain coagulating power. This power is variable, depending on the tissue, the individual, and the locality from which the tissue was taken. The coagulating power is greatest in the epiploic ext., and least in the aponeurotic; the muscular and adipose tissues lie between these two extremes and are about equal. In even the most concd. exts. the differences are small, so that for the purposes of practical surgery these tissues may be regarded as equal in hemostatic power. H. W. BANKS, 3d.

Muscle chemistry. IX. Organic and inorganic phosphorus of the smooth and striated muscular tissue of birds; formation of phosphoric acid during the autolysis of muscular tissue of birds. A. COSTANTINO. Univ. Pisa. *Arch. farm. sper.* 20, 276-302 (1915); cf. *C. A.* 9, 1073.—Striated muscle of birds (chicken) is higher in total P, sol. P, and inorg. P, than smooth muscle. Both contain an appreciable amt. of sol. org. P. White muscle is richer in sol. P and inorg. P than red muscle. Phosphatide P and protein P occur in smaller amts. in white striated than in red striated or in smooth muscle. Total P and sol. P are higher in striated muscle of birds than in that of mammals. Total P, sol. P, inorg. P, phosphatide and protein P in smooth muscle of birds are higher than in that of mammals. The relative proportions of inorg. and org. P. are practically identical for the three kinds of muscle. During autolysis of striated and smooth muscular tissue of birds there is an increase in inorg. P. X. Chemistry of the phosphorus-containing substances of smooth muscular tissue of mammals. *Ibid* 361-70.—The phosphorylated proteins of the smooth muscular tissue of mammals belong to the nucleoproteins. Part of the nucleoproteins of smooth muscle can be extd. by physiological NaCl soln. A. W. DOX.

Anaphylactic shock produced by the blood of a woman in guinea pigs sensitized by placental proteins. F. D'HERELLE AND L. GÉRY. *Compt. rend. soc. biol.* 78, 55-8 (1915).—Guinea pigs which received 2 cc. of the ext. (prepd. with physiol. NaCl soln.) of a fresh placenta (free from blood) died with symptoms of cachexia. Guinea pigs which were sensitized by intraperitoneal injection of 1 cc. ext. (corresponding to 0.036 mg. of dried protein as detd. by comparisons with horse serum pptd. by alc.) survived; after 35 days these animals were used for the following expts.: Injection of 1 cc. of the serum of a man failed to produce anaphylactic crisis and the animals survived. Injection of 1 cc. of the serum of women (at various stages of pregnancy or non-pregnant and either virginal or non-virginal) invariably resulted in anaphylactic crisis

and death in 1-26 mins. Injection of 1 cc. of the centrifuged blood from the umbilical cord of a still-born, male infant failed to produce anaphylactic crisis. It is concluded that the blood of woman contains throughout life certain sp. proteins which are identical with those which are present in placental tissue. H. S. PAINE.

Formation of creatine in the animal organism. ALEXANDRE PALLADIN AND I. WALLENBURGER. Petrograd. *Compt. rend. soc. biol.* 78, 111-3(1915).—P. and W. have studied the possibility of the formation of creatine from glyco cyanamine in the animal organism in view of the contradictory data relating to the theory that creatine is produced from arginine with glyco cyanamine as an intermediate substance. Autolysis of the muscles of rabbits showed a content of 0.574-0.678% creatine, the period of autolysis being variable; when 1 g. glyco cyanamine was added, the corresponding amts. of creatine obtained varied between 0.806 and 1.426%. When 3.5-4.5 g. glyco cyanamine were injected subcutaneously (in 0.5 g. doses 3 times per day) in rabbits the creatine content of the muscles was found to be 21.5-35.6% greater than in normal rabbits; the creatine content of the muscles of the latter was nearly const., showing a variation between 0.517 and 0.545% (av. = 0.525%). Autolysis of the muscles of *Lotta vulgaris* with addition of glyco cyanamine also showed an increased content of creatine; the transformation of creatine was, however, considerably slower than in the case of rabbit muscles. The normal creatine content of the muscles of *L. vulgaris* was found to be 0.512-0.541% (very nearly the creatine content of rabbit muscles). It is concluded from the foregoing expts. that glyco cyanamine is transformed into creatine under physiol. conditions. H. S. PAINE.

Internal secretion of the testicles. RENZO ROVEDA. Modena. *Pensiero med.* 3, 803-7; *Zentr. Biochem. Biophys.* 18, 114(1915).—The testicles possess a true internal secretion which contains substances which play a part in the development of the secondary characteristics of male sex. H. S. PAINE.

Presence of skatole in the distillate from urine. P. BINDA. Pavia. *Gazz. med. ital.* 64, 301-2; *Zentr. Biochem. Biophys.* 18, 121(1915).—The distillate (also the CHCl_3 ext. of the distillate) from human and dog urine, when subjected to the Ehrlich test, assumed a wine red color which in the case of the CHCl_3 ext. became lighter in color after several days and finally assumed a bluish red color. This reaction must be attributed, not to indole, but to a substance which caused the color change of the indole reaction. This reaction is probably due to skatole, inasmuch as the latter was isolated from a 2nd distillate which had been acidified with HCl ; skatole was obtained as glistening red crystals after repeated extn. with Et_2O and soln. in satd. picric acid and C_6H_6 , etc. Detection of skatole in the urine is believed to possess clinical significance. H. S. PAINE.

Compounds of the benzene series which are present in sputum. P. BINDA AND CASSARINI. Pavia. *Gazz. med. ital.* 64, 461-3; *Zentr. Biochem. Biophys.* 18, 121(1915).—B. and C. have studied the compds. of the C_6H_5 series which have their origin in processes of putrid decompn. and are eliminated in the sputum and which sometimes accumulate in the bronchi and pulmonary cavities. Indole, either as such or as an indole-producing substance, is frequently present in the sputum, but this compd. does not necessarily originate from decompn. processes in the sputum itself. Indole may also, in such cases, be derived from the blood and may pass directly into sputum with effusions or by means of exudative and transudative processes. H. S. P.

Changes in the content of fatty substances of striated muscles during the first few hours after death. R. ROMANESI. Turin. *Liguria med.* 7, 200; *Zentr. Biochem. Biophys.* 18, 122(1915).—Detn. of the fat content of the same muscle immediately after death and 24, 48 and 72 hrs., resp., subsequent thereto indicated that the fat content first undergoes a decrease and then an increase. More exact study of the be-

havior of the satd. and non-satd. fatty acids showed that both participate in the decrease in the total fat content, but that the subsequent increase is due exclusively to the non-satd. fatty acids. The change during the 1st period is doubtless due to genuine fat consumption, while that in the 2nd period is probably caused by synthesis due to putrefactive bacteria.

H. S. PAINE.

Influence of alanine on bile secretion. FILIPPO LUSSANA. Bologna. *Bull. sci. med.* 84, 557-68; *Zentr. Biochem. Biophys.* 18, 125-6(1915).—Alanine, when administered *per os* in amts. of 5-20 g., caused a considerable increase in the bile secretion of dogs which had been fasting for 21 hrs. previously; sugar in similar amts. had not the slightest influence on the formation of bile. Stimulated secretion was first manifested by an increase in the H₂O content of the bile and subsequently by an increase in the free constituents thereof.

H. S. PAINE.

Viscosity of endolymph and perilymph. GILBERTO ROSSI. Florence. *Arch. fisiol.* 12, 415-28; *Zentr. Biochem. Biophys.* 18, 130(1915).—R. detd. the relative viscosity of the endolymph and perilymph of the pigeon. In view of the small amt. of liquid which is available for such expts. an especial method for detg. viscosity in instances such as the above is described. Measurements at 18-20° showed relative viscosity values of 2.9 and 1.7, resp., for endolymph and perilymph.

H. S. PAINE.

Blood sugar content of new-born and prematurely born children. FRITZ HELLER. Univ. Strassburg. *Z. Kinderheilk.* 13, 129-34(1915).—Values are given of the blood sugar content for 15 cases (3 prematurely born) during the 1st 9 days; they vary from about 0.066 to 0.12%. The age, the amt. or kind of food, and the time of feeding appear to have no influence upon the amt. of blood sugar.

H. GIDEON WELLS.

Formation of immune bodies by means of different typhoid vaccines. O. LÖWY. *Deut. med. Wochschr.* 41, 1277-8(1915).—Rabbits received injections of typhoid bacilli killed by heating for 1 hr. at 56°, bacilli killed with EtOH and living bacilli sensitized according to Besredka using a great excess of highly agglutinating horse serum. The serum of rabbits having received bacilli killed by heat or by ether showed a high agglutinating titer; that of rabbits treated with sensitized bacilli did not possess any greater agglutinating power than serum of normal animals. The bactericidal power of the serum was the same in all the instances, while the treatment with sensitized bacilli yielded a serum of greater complement-fixing power.

S. AMBERG.

The irrationality of bacterial vaccines in the treatment of pyorrhea alveolaris. ARTHUR H. MERRITT. New York City. *Dental Cosmos* 58, 62-9(1916).—The use of bacterial vaccines in pyorrhea alveolaris is irrational because the bacterial flora is exceedingly complex, and there is no evidence that any of the organisms produces the disease. The antibodies in the blood and lymph are practically without effect on the organisms in the pyorrheal pockets. The difference between the bacteriology of the normal mouth and that of pyorrhea is merely quant., not qual. Vaccines liberate protein poison, a drawback to their use.

JOSEPH S. HEPBURN.

The biologic co-relation of the law of similars. RALPH R. MELLON. Ann Arbor, Mich. *J. Am. Inst. Homeopathy* 8, 784-91(1916).—M. points out certain phenomena in physical chemistry and in immunity which are in harmony with the law of similars.

JOSEPH S. HEPBURN.

Metabolism in the severe chronic anemias of man. E. GRAFF. Heidelberg. *Deut. Arch. klin. Med.* 118, 148-62(1915).—In an earlier work (*Münch. med. Wochschr.* 59, 2840(1912)), it was found that the metabolism of rabbits made anemic by bleeding was normal, or somewhat raised, while that of rabbits made anemic by poison-

ing with phenylhydrazine was lowered. The object of the present work, is to find whether the same holds true with man. Ten cases of severe chronic anemia, 3 produced by severe hemorrhages into the stomach and 7 being pernicious anemia, were studied as to the respiratory quotient, N output, and heat production. In all, the heat production per kg. body wt. varied from 25.1 to 34.7 cal.. These figures are the normal ones and in none was there found the subnormal values as in phenylhydrazine poisoning in rabbits.

JULIAN H. LEWIS.

The influence of bleeding on the rest nitrogen of the blood serum in uremia. S. GUTMANN AND L. WOLF. Berlin. *Deut. Arch. klin. Med.* 118, 174-8(1915).—Whether or not there is any improvement after bleeding, or whether the amt. of blood removed was small or large, the rest N content varied only within narrow limits. Of the 22 cases investigated, 14 showed an increase and 8 a decrease. There was an increase in 6 of the 9 that showed improvement and a decrease in 3. In all cases only 3 showed a variation over 20%.

JULIAN H. LEWIS.

Lipase and leucocytes. ALFRED RESCH. Zurich. *Deut. Arch. klin. Med.* 118, 179-89(1915).—It was found that the lymphocytes are the origin of the lipolytic enzyme found in an exudate produced by injecting lecithin into the pleural cavity. The optimum action of the enzyme was at the true neutral point and at the H-ion concn. of the blood. Morphologically, the mononuclear cells in the exudate are lymphocytes and are of hematogenous origin.

JULIAN H. LEWIS.

The influence of the extirpation of the liver on the temperature and respiratory quotient. E. GRAFE AND G. DENECKE. Heidelberg. *Deut. Arch. klin. Med.* 118, 249-66(1915).—The most marked results of the extirpation of the liver were a fall in the body temp. and a great increase in the respiratory quotient. It is believed that these changes do not indicate any change in the metabolism of the carbohydrates, even though there is an increase in the CO₂ output from the blood. With the rise of CO₂ in the expired air there is a decrease in the blood, while in the case of increased carbohydrate oxidation, the increase of CO₂ in the blood and expired air, are parallel.

JULIAN H. LEWIS.

The influence of muscular work on blood sugar. W. VON MORACZEWSKI. Carlsbad. *Berl. klin. Wochschr.* 52, 1038-9.—A series of expts. was conducted to show the effect of muscular work on the blood sugar after certain diets. It is shown that after work the sugar is increased, but much more after a carbohydrate meal or if the organism is well nourished than during starvation. A large amt. of sugar can be assimilated as the result of hard work provided the organism has a tolerance for sugar. A diabetic with just an inclination to glucosuria accumulates sugar in the blood much more easily and on a diet with which a normal man would hardly show any increase in the blood sugar; with a carbohydrate diet, the increase is still more marked. It is suggested that these methods be used in detecting slight inclinations to glucemia. Another difference between normal people and diabetics is that the latter excrete more uric acid after work.

JULIAN H. LEWIS.

The clinical advantage of bile analysis in disease. EMIL MEDAK AND BRUNO OSKAR PRIBRAM. Vienna. *Berl. klin. Wochschr.* 52, 706-9, 740-3(1915).—The quant. analysis of the pigment and cholesterol in bile removed from the duodenum by means of a tube can assist in making prognoses and in detg. the indications for treatment in many different diseases. The methods of detg. the pigments and cholesterol are given.

JULIAN H. LEWIS.

The influence of milk and its antibodies on the action of hemolytic toxins. H. SACHS. Frankfurt a/M. *Berl. klin. Wochschr.* 52, 764-7(1915).—In the toxin from the garden spider there is a hemolytic element called by S. "arachnolysin" and by others

"epiralyain." It lyses beef and rabbit blood but not guinea-pig or sheep blood. Cells of the guinea-pig tissues, however, possess binding receptors for the toxin, because an antitoxic serum can be obtained by immunizing guinea pigs with the arachnolysin. Toxins may have 2 sorts of antitoxins, one which unites specifically with the toxin, as does diphtheria antitoxin, and another which unites with the receptors of the cells, thus depriving these cells of the ability of anchoring the toxin. Cow milk can inhibit the hemolytic action of arachnolysin for both beef and rabbit blood. This antitoxic action is destroyed by heating to 65° for 1/2 hr. There is no quant. difference in its action if the milk is incubated for a long while before injection. It is believed that there are in milk the sort of antibodies which act by satg. the toxin binding cells of the body. The difference between heated and unheated milk in their action on arachnolysin can be used for their differentiation.

JULIAN H. LEWIS.

Comparison of the Wassermann and the Hermann-Perutz syphilis tests. J. ZADREK. *Neukölln. Berl. klin. Wochschr.* 52, 893-5(1915).—The technic of the Hermann-Perutz test for syphilis is as follows: To 0.4 cc. of the hemoglobin-free inactivated serum is added 0.2 cc. of a 2% aq. soln. of Na glycocholate and 0.2 cc. of a soln. composed of 2 g. of Na glycocholate, 0.4 g. cholesterol, and 100 g. of 96% alc. If, after standing for 20 hrs., a distinct ppt. is produced, the reaction is considered to be positive. In the examn. of 1000 cases of syphilis in all stages, it was found that 51.2% gave a positive Wassermann and 72.7% a positive Hermann-Perutz test. With a large number of controls, 94.4% gave a negative Wassermann and 89% gave a negative Hermann-Perutz test. The latter test was not specific in severe pulmonary tuberculosis, carcinoma, typhoid, sepsis, uremia, and eclampsia. In the examn. of cerebrospinal fluid, it was non-specific only in uremia and eclampsia.

JULIAN H. LEWIS.

Brain lipoid as a hemostatic. ARTHUR D. HIRSCHFELDER. *Univ. Minn. Berl. klin. Wochschr.* 52, 976-7(1915).—By actual tests on experimental animals it is shown that the lipoidal substance prepared from ox brain could control hemorrhages. It stopped the bleeding that occurred during tonsillectomy. On account of its cheapness and ease of prepn., this substance lends itself to many fields of application, especially in field and emergency surgery.

JULIAN H. LEWIS.

The effect of acute serous meningitis on the metabolism of a diabetic. L. LICHTWITZ. Göttingen. *Berl. klin. Wochschr.* 52, 996-8(1915).—A patient who was convalescing from typhoid was being treated for diabetes. Careful analysis of the urine showed that he was improving; the sugar balance was positive, the acidosis was sinking, and there was a retention of N. On the fifth day the patient developed meningitis with a very high fever and as a result marked changes in the metabolism occurred. The vol. of urine increased about 4 times. The total N output increased from 7.39 g. to 30.9 g. Likewise the "acetone bodies" and NH₃ increased. He was given 30.2 calories of food per kg. body wt. but on account of the great excretion of sugar only 19.2 were utilized and consequently he was undernourished. The output of sugar was much over the intake, showing that the source of the excess was the broken down protein, because, being a diabetic patient, his tissues were glycogen-free. It is believed that these developments were the direct influence of the acute infection.

JULIAN H. LEWIS.

The miostagmin reaction with malignant tumors. O. WISSUNG. Copenhagen. *Berl. klin. Wochschr.* 52, 998-1001(1915).—The miostagmin reaction was made on 500 patients with malignant tumors and 350 patients with non-malignant tumors and other affections. A 2% soln. of linseed and castor oils in abs. alc. was used as antigen, and Frank's stalagmometer was used to measure the reaction. A positive reaction was obtained with 84% of the malignant tumors. Most were inoperable carcinomas. None of the non-malignant tumors gave a reaction. All febrile conditions gave a

positive reaction but only for a few days after the disappearance of the fever. All cases of pregnancy gave positive reactions in the last 3-4 months, but not 2 weeks after parturition. Cardiac disease with decompensation, cirrhosis of the liver, icterus gravis, pulmonary tuberculosis, severe diabetes mellitus, chronic rheumatic polyarthritis, chronic nephritis, and uremia gave positive reactions. Although the reaction is not specific it may be of assistance in the early diagnosis of carcinoma.

JULIAN H. LEWIS.

Practical application of the complement-fixation test. M. TSURUMI. *Berl. klin. Wochschr.* 52, 1142(1915).—By using exts. of bacteria instead of a suspension of whole bacteria, the complement-fixation test could be made so delicate that *B. paratyphosus* could be differentiated from *B. typhosus*.

JULIAN H. LEWIS.

The Wassermann reaction in pemphigus. ERNST NATHAN. Frankfurt. *Berl. klin. Wochschr.* 52, 1183(1915).—All cases of pemphigus vegetans and vulgaris, in which syphilitic infection was absent either from the history or clinically, the Wassermann reaction was negative. This is in direct contradiction to a statement made by Hesse that a positive Wassermann reaction is characteristic of pemphigus.

JULIAN H. LEWIS.

The significance of the virulence and morphological conditions of bacteria in immunization and the immunizing action of autolyzed cultures. ERICH TOENNIESSEN. *Centr. Bakt. Parasitenk., Abt. I* 76, 262-75(1915).—To study this question a strain of Friedländer's bacillus was studied. It was highly virulent, had a broad capsule and a well developed ectoplasm and endoplasm. This strain could be divided into 2 variants, one called the fluctuant and the other the mutant. The former was avirulent; it possessed a broad ectoplasm and endoplasm but no capsule. The mutant was also avirulent, possessed a meager endoplasm, only a barely visible ectoplasm, and no capsule. Twenty-four-hr.-old, killed, agar cultures of the stem strain and of the fluctuant strongly immunized mice and guinea pigs while the mutant did so only slightly. This shows that neither the virulence nor the possession of a capsule has any significance in affecting the immunizing properties of these bacteria. The most active part in immunization seems to be the ectoplasm. The immunizing relations of the bacteria were obtained with the use of autolyzed cultures.

JULIAN H. LEWIS.

The mechanism of the Abderhalden reaction with bacterial substrates. G. H. SMITH AND M. W. COOK. Glenolden, Pa. *J. Infect. Dis.* 18, 14-9(1916).—A bacterial immune serum when combined with its specific substrate in the cold and subsequently dialyzed alone undergoes some degradation, as is indicated by a positively reacting dialysate. This same serum, when combined in an identical manner with heterologous substrates, is not digested. A typhoid substrate which has been in contact with a typhoid serum in a specific union, now so acts upon all the sera (typhoid, paratyphoid A, *Staphylococcus aureus*, and normal) so that each serum upon subsequent dialysis gives a positive reaction. This reaction occurs with other bacteria but it is specific, that is, bacteria cannot be acted on by any other than its own antiserum so that it will cause a digestion when mixed with other sera. A previous contact of a substrate with a non-specific serum in no way impairs its activity when subsequently combined with a specific serum. It is thought that these expts. confirm the ideas of Bronfenbrenner and others that the substrate adsorbs antitrypsin and permits autodigestion of the serum.

JULIAN H. LEWIS.

Studies in non-specific complement fixation. I. Non-specific complement fixation by normal rabbit serum. JOHN A. KOLMER AND MARY E. TRIST. Univ. Pa. *J. Infect. Dis.* 18, 20-7(1916).—Fresh active serum from normal rabbits in doses of 0.1 cc. showed non-specific complement fixation with lipoidal exts. in 5-15% of sera. When these same sera were inactivated by heating them in a H₂O bath at 55-56°

for 30 min., complement fixation occurred in 38-49% of sera. With both active and inactive sera the highest percentage of positive reactions was observed when alc. exts. of heart muscle re-enforced with cholesterol were used as antigen; alc. exts. of syphilitic liver gave the 2nd highest, and an ext. of acetone-insol. lipoids gave the lowest percentage of positive reactions. With bacterial antigens of staphylococcus, colon and typhoid bacilli, fresh, active rabbit sera showed some degree of complement fixation in 31-42% of instances; when these sera were inactivated, positive reactions occurred in 51-62%. The degree of complement fixation with normal rabbit serum and lipoidal and bacterial antigens is usually moderate or slight, as about 50-85% of reactions show 50%, or less, inhibition of hemolysis. The reacting state of a rabbit's serum when the animal is on an av. diet is usually const., in that 80% of the animals used in these expts. reacted persistently negatively or persistently positively when examd. at intervals of 3 days or a month. It is emphasized that when rabbits are used for experimental studies with a view of using their sera for complement-fixation tests, their sera should be tested one or more times before inoculation, preferably with the particular antigen to be used, and only those selected that react negatively. II. *Non-specific complement fixation by normal dog serum.* JOHN A. KOLMER, MARY E. TRIST, AND GEORGE D. HEIST. *Ibid* 27-31.—Like rabbit serum, dog serum has a tendency to fix complement in a non-specific manner which is increased by heating at 56° for 30 mins. It is less likely to be non-specific, however, after heating at 62° for 30 mins. III. *The influence of splenectomy and anesthetics on the non-specific complement fixation sometimes shown by normal rabbit and dog sera.* JOHN A. KOLMER AND RICHARD M. PEARCE. *Ibid* 32-45.—Anesthetics, as ether, CHCl₃, and to a slight extent urethan, generally weaken or remove temporarily the power in normal rabbit and dog sera of absorbing or fixing complement with lipoidal and bacterial antigens in a non-specific manner. This alteration is usually not apparent at once after the administration of the anesthetic, but is found 1-3 days after; later the serum returns to its former power of causing this non-specific complement fixation. The administration of ether does not alter negatively reacting sera in such a manner as to bring about a positive reaction. N₂O anesthesia has no appreciable influence on the serum reactions of normal rabbits. Splenectomy alone has probably no influence upon the property in normal rabbit and dog sera of fixing or absorbing complement with various non-specific lipoidal and bacterial antigens, the effects being in a larger degree attributable to the anesthetic; the changes observed in dogs following splenectomy under ether were somewhat more profound than those in rabbits. IV. *The relations of serum lipoids and proteins to non-specific complement fixation with normal rabbit and dog sera.* JOHN A. KOLMER. *Ibid* 46-63.—Both the serum lipoids and proteins are concerned in the antilytic and non-specific complement-fixation reactions with normal rabbit and dog sera. The role of the serum lipoids in these processes is indicated in the observation that extn. of suitable sera with ether and CHCl₃ usually diminished the antilytic and complement-fixing powers of a serum, whereas the enteral and parenteral administration of lipoids increased the antilytic and complement-fixing powers. Sera that are extd. with ether are rendered primarily more antilytic; after heating an extd. serum the antilytic titer is generally reduced, as compared with the titer of plain heated serum. Both the globulin and albumin (filtrate) fractions of normal rabbit and dog sera possess thermostable antilytic and complement-fixing properties, usually the former to a slightly greater degree. The antilytic and complement-fixing substances of normal rabbit and dog sera are not dialyzable. V. *The effect of heat on normal rabbit and dog sera in relation to antilytic and non-specific complement-fixation reactions.* JOHN A. KOLMER AND MARY E. TRIST. *Ibid* 64-87.—Non-specific complement fixation by normal rabbit and dog sera is probably due primarily to thermolabile and thermostable antilytic (anticomplementary) substances in the sera. While fresh and active

rabbit and dog sera may yield non-specific complement fixation, the tendency is greatly increased as a result of heating the sera. At 56° the changes may occur in 20 min. or even sooner; at 62° for 30 mins. the tendency for non-specific reactions is much decreased, and is entirely removed by heating serum at 70° for 30 min., but the optimum temp. is between 55° and 60°. In complement-fixation tests for specific antibodies with inactivated rabbit, dog, and mule sera, it is advisable to heat the sera at 62° for 30 mins. and to use at least 2 units of complement or hemolysin and no more than 1/4 of the anticomplementary unit of antigen after it has been carefully titrated. Complementoids and amboceptoids probably bear no relation to the process of non-specific complement fixation by rabbit and dog sera. The blood corpuscles of various animals and various bacteria may absorb a portion of the antilytic substance from rabbit and dog sera, but they have much less influence on the complement-fixation reactions. Digestion of fresh sera with corpuscles and bacteria frequently increases the anticomplementary properties of the sera. Bacteriolytic amboceptors are not responsible for non-specific complement fixation by normal rabbit and dog sera. Parasitic infestations bear no relation to the antilytic and anticomplementary reactions of the sera. Single, large doses of salvarsan are without effect on the reactions with rabbit serum. Quantitative factors in the hemolytic system and antigen are of considerable importance in relation to these non-specific reactions.

JULIAN H. LEWIS.

Complement fixation in intestinal parasitism of dogs. JOHN A. KOLMER, MARY E. TRIST AND GEORGE D. HEIST. Univ. Pa. *J. Infect. Dis.* 18, 88-105(1916).—According to the results of complement fixation on a large number of dogs infested with intestinal parasites, it is believed that there may occur in the serum of the dog antibodies which are specific for these parasites. Production of antibodies was especially in evidence in infestations with tapeworms, to a less degree with the ascarides or round worms, and to a slight extent with the whip worm. The complement fixations have tended to show a biologic relation between the tapeworms, *Tenia serrata* and *Dipylidium caninum* and between *Ascaris canis* and *Strongylus gigas*, although on account of the wide morphological differences this question is left open; it is probable, therefore, that with the usual technic the complement-fixation test will not differentiate between related species of parasites, although it may show the presence of the parasite.

JULIAN H. LEWIS.

The value of virulent salt solutions in the production of anti-hog-cholera serum by the intravenous method. ROBERT GRAHAM AND L. R. HIMMELBERGER. Lexington, Ky. *J. Infect. Dis.* 18, 118-23(1916).—A NaCl soln. virus was made by injecting 25 cc. per lb. body wt. of sterile 0.9% NaCl soln. into the peritoneal cavity of virus pigs at least 5 hrs. before killing, when the NaCl soln. was removed aseptically. The intravenous injection of this virus together with the blood virus, reduced the cost of production of anti-hog-cholera sera. The strength of the antisera produced was equal to that produced in other ways.

JULIAN H. LEWIS.

The acid-base equilibria in the blood after parathyroidectomy. D. W. WILSON, THORNTON STEARNS AND MADGE DEG. THURLOW. Johns Hopkins Univ. *J. Biol. Chem.* 23, 89-109(1915).—A study was made of the variations of the values of the dissociation const. of oxyhemoglobin, the alveolar CO₂ pressure, and the H-ion concn. of the blood of parathyroidectomized dogs. After the removal of the parathyroids from dogs there may develop a condition of alkalosis in which the basic radicals in the blood are relatively increased over the acid radicals, disregarding CO₂. This alkalosis is counteracted by the acid products formed by the muscular activity incident to the tetany which neutralizes the excess of bases and may even produce an acidosis, which brings about relief from tetany in the same manner as injection of acid. Ca salts, injected into animals in tetany, lower the value of the dissociation const. of oxy-

hemoglobin and the alveolar CO_2 pressure, the action being similar to that due to the administration of acids, and apparently these salts produce a condition of artificial acidosis which is favorable for a relief from tetany.

A. P. LOTHROP.

The excretion of acids and ammonia after parathyroidectomy. D. W. WILSON, THORNTON STEARNS AND J. H. JANNEY, JR. Johns Hopkins Univ. *J. Biol. Chem.* 23, 123-37(1915); cf. preceding abstract.—A sudden diminution in acid and NH_3 excretion and a decrease in the NH_3 ratio and the H-ion concn. of the urine usually occur after parathyroidectomy in dogs. With the development of tetany there is an increase in all these factors. Apparently a condition of alkalosis is primary and acidosis develops only secondarily during tetany after neutralization of the excess of bases by the acid products of muscular activity. An alkalosis period may recur unless the tetany is sufficient to maintain the acidosis.

A. P. LOTHROP.

Rotatory power of plasma in various diseases. G. GASTALDI. Turin. *Chim. med. ital.* 52, 433-42; *Zentr. Biochem. Biophys.* 18, 130-1(1915).—G. has made numerous studies of the rotatory power of blood plasma in various diseases. Levorotation was observed to be very irregular during the course of any given disease. The observed differences in rotatory power appeared to be connected with the various stages of acute disease conditions and, in chronic affections (especially those which produced cachexia), with the condition of nutrition of the individual in question.

H. S. PAINE.

Gaseous gangrene. EDNA S. HARDE. Inst. Pasteur. *Compt. rend. soc. biol.* 78, 18-20(1915).—The following observations were made in the case of wounded soldiers where *B. perfringens* (usually associated with other bacteria) was the active agent in gas production in the 1st stage of gaseous gangrene. It appeared that the acute intoxication of the 1st stage might be due not only to sol. toxins, but also to absorption of gas (H_2S , NH_3 , CO_2 and H have been found in such gas). NaNO_2 was therefore administered both locally and *per os* in an attempt to control this gas production; evolution of gas was quickly checked in all instances where this treatment was employed and a general amelioration of the condition resulted. The diuretic action of NaNO_2 may possibly play an extensive part in the extremely rapid detoxication and possibly other diuretics would have the same beneficial action in this respect.

H. S. PAINE.

Sodium citrate and agglutination of the typhoid bacillus. A. SARTORY AND PH. LASSUR. *Compt. rend. soc. biol.* 78, 36-8(1915).—Expts. in which 1-10 pts. by vol. of a 3:1000 Na citrate soln. were added to agglutinating serum and a const. vol. of 20-hr. typhoid bacillus culture so as to make a const. final vol. of 21 parts indicated that the presence of Na citrate may lead to false conclusions by slightly increasing agglutination in the case of a serum which possesses weak agglutinating power. No agglutination was observed when as much as 4 pts. of a 5:1000 Na citrate soln. were mixed with 1 pt. of the bacterial culture and the agglutinating serum was omitted. Na citrate, even in 15:1000 soln., failed to promote agglutination when used in connection with non-agglutinating serum from a typhoid fever suspect. In another instance a guinea pig which yielded non-agglutinating serum on puncture of the marginal vein of the ear subsequently received an intraperitoneal injection of 5 cc. of a 2% Na citrate soln.; blood drawn at 4 successive periods thereafter failed to show agglutinating action.

H. S. PAINE.

Acute appendicitis produced by a medicinal calculus of bismuth carbonate. ER. BARRAL. *Compt. rend. soc. biol.* 78, 72-3(1915).—B. records some results of auto-observation. As a result of an intestinal hemorrhage resulting from an ulcer of the duodenum the usual treatment with Ca lactate and Bi carbonate in large doses was instituted. Six months thereafter an operation for acute appendicitis became necessary. A calculus which was removed weighed 0.37 g. and was composed of a mixt. of Bi

sulfide and carbonate with albuminoid material; the central nucleus contained 69.5% Bi carbonate.

H. S. PAINE.

Anaphylactic origin of nervous affections caused by intestinal worms. DEMETRIE E. PAULIAN. *Compt. rend. soc. biol.* 78, 73-5(1915).—The nervous derangements, eosinophilia and blood reactions observed in cases of intestinal worms are indicative of anaphylaxis and it is concluded that these nervous affections are due to anaphylactic shock caused by helminthiac toxins. These toxins do not differ in constitution from those of proteins in general and hence are capable of producing the same anaphylactic phenomena.

H. S. PAINE.

The urochromogen reaction in the urine of tuberculous individuals. B. NICOLA. Turin. *Gazz. osped.* 34, 1479-81; *Zentr. Biochem. Biophys.* 18, 120(1915).—The urochromogen reaction proposed by Weisz was found to be constantly positive in cases of pulmonary tuberculosis.

H. S. PAINE.

Significance of the Weisz permanganate reaction in the urine. ENRICO SALUSTRI. Camerino. *Il policlín.* 20, 1730-3; *Zentr. Biochem. Biophys.* 18, 120(1915).—A distinct permanganate reaction of const. occurrence in the urine of patients who are seriously ill indicates that the nature of the disease process is tuberculous and it may be concluded that the infection is in an advanced stage; when the Weisz reaction is negative or indistinct in such patients tuberculosis may be excluded. A positive permanganate reaction does not necessarily indicate tuberculosis in the case of mild disease aspects.

H. S. PAINE.

Lesions of the viscera in experimentally produced pancreatic necrosis. C. GRANDE. Turin. *Liguria med.* 7, 200; *Zentr. Biochem. Biophys.* 18, 117(1915).—G. has studied the extended histological lesions of the viscera which appear in death by pancreatic necrosis or following the introduction of pancreatic enzymes into the abdominal cavity. These lesions were observed in the liver in connection with necrotic and hemorrhagic areas and, in the kidneys, in connection with deposits of blood pigment (lesions were also observed in the suprarenals, spleen and pancreas). Other histological observations are described. These results constitute an argument in favor of the toxic theory of death as a result of pancreatic lesions and render it probable that the toxic effect is essentially dependent upon the action of the proteolytic enzyme.

H. S. PAINE.

Determination of residual nitrogen in the blood as a method for the testing of kidney function. H. HOHLWEG. Giessen. *Mon. Grenzgeb.* 28, 459-78(1915); *Zentr. Biochem. Biophys.* 18, 118(1915).—No increase in the residual N of the serum was observed in unilateral renal affection; a normal residual N value indicates, therefore, that at least 1 of the kidneys is capable of function. The residual N value was also maintained at the normal value after unilateral nephrectomy. The residual N value was increased in cases of bilateral renal suppuration or unilateral suppuration with toxic impairment of the other kidney. Nephrectomy is still indicated for residual N values up to 75 mg.; values of 100 mg. residual N in 100 cc. serum, however, unqualifiedly forbid the extirpation of a kidney. The residual N values are temporarily higher during the 1st few days or even weeks following nephrectomy than before the operation.

H. S. PAINE.

A supposed soluble toxin, produced in artificial culture by the bacillus of malignant edema. G. BARGER AND H. H. DALE. *Brit. Med. J.* 1915, II, 808-9.—The bacillus of malignant edema was grown for 6 days on minced ox heart in an atm. of H₂, and the resultant culture fluid was filtered through paper and a Berkefeld filter. 3-5 cc. of the filtrate were required to kill a 300 g. guinea pig. The large vol. required to produce symptoms, their immediate onset and the necessity of solid meat as a culture medium suggested a non-specific product of putrefaction as the toxic agent. Brief boiling and filtration through collodion did not affect the toxicity. The active agent

could not be concd. even at low temp. and pressure, but could be distd. from the alk. fluid. From 150 cc. of the collodion-filtered "toxin," volatile bases sufficient to neutralize 113.2 cc. NH_4SO_4 were obtained. Animal tests showed the NH_4 -containing fraction of the volatile bases to be responsible for the toxic action. A. H. RAHE.

Gastroalbumorrhoea in gastric cancer. MAX KAHN AND I. JACOBOWITZ. *Med. Record* 88, 1006-7(1915).—In the stomach-washings from 15 cases of gastric cancer the N content varied between 27.9 and 71.5 mg. per 100 cc., while washings from 3 cases of esophageal carcinoma gave figures intermediate between these. Parallel detns. of albumin by the Esbach, Tsuchiya, and Pfeiffer methods are given. Washings from cases of non-gastric disease never contained more than a trace of protein, whereas in cases of cancer the protein content was invariably high (0.4 to 1.2 parts per thousand).

A. H. RAHE.

Occurrence of acidosis in children. E. C. WILLIAMS. *Brit. J. Children's Dis.* 12, No. 143(1915); *J. Am. Med. Assoc.* 66, 64.—Thirteen cases between the ages of 3 and 11 years were studied, some of which were complicated by pneumonia or food poisoning. W. emphasizes the importance of an examn. of the urine for acetoacetic acid and acetone, also for *B. coli* in all cases of doubtful origin. L. W. RIGGS.

Proteolytic ferments of the blood serum in tabes dorsalis and general paresis. F. H. FALLS. Chicago Univ. *J. Am. Med. Assoc.* 66, 22-4(1916); cf. *C. A.* 9, 655, 1936, 2665.—From expts. in 9 cases of tabes dorsalis, 6 of general paresis, and, as controls, 5 of meningitis and 10 of pregnancy F. concludes that the enzyme activity of the blood serum is increased above normal in general paresis, and a lesser increase occurs in tabes dorsalis.

L. W. RIGGS.

Diabetes insipidus and functioning of the hypophysis. K. MOTZFELDT. *Norsk Magasin Laegevidenskaben* 76, No. 11(1915); *J. Am. Med. Assoc.* 65, 2206.—Three cases are reported, in one of which the intake and output of fluids, with the detn. of sp. gr., chlorides, and N, were recorded daily for 3 months while under treatment with an ext. of the posterior lobe of the pituitary substance. A marked improvement followed, the patient being apparently well. The treatment was continued with pituitary substance obtained fresh from the slaughter houses and eaten raw or cooked. The ext. of the anterior lobe seemed to have no action. In a second paper M. reports the administration of the ext. of the posterior lobe to 15 relatively healthy persons resulting in a diminution of the quantity of urine, but the amt. of N was unaffected.

L. W. RIGGS.

Postural albuminuria in relation to nephritis. P. F. HOLST. *Norsk Magasin Laegevidenskaben* 76, No. 11(1915); *J. Am. Med. Assoc.* 65, 2206.—Post-mortem examn. of a youth, who had had typical orthostatic albuminuria for 5 or 6 years, but who died of quick tuberculosis of the lungs, failed to show any traces of inflammation of the kidneys. Ten cases are cited in which orthostatic albuminuria was a chronic condition, but no tube casts were found in the urine. Such cases should be carefully distinguished from true nephritis in order to administer appropriate treatment.

L. W. RIGGS.

Analysis of a calcareous concretion observed in fatal case of heart disease. M. ACREMANN. *J. pharm. chim.* 12, 253-5(1915).—The concretion, in the case of a woman of 52 yrs., was one of pericardial symphysis, a whitish, translucent mass, of conchoidal fracture, horny and friable exterior and up to 2 cm. thick. Its % compn. was: H_2O , 16.40; fat and other Et_2O -sol. matter, 3.68; ash, 57.03; albuminoid matter, etc. (by difference), 22.99%. The ash includes 48.53% $Ca_3(PO_4)_2$ and 2.78% $CaCO_3$. The mode of combination of 1.10% Ca out of a total of 20.99% remains unaccounted for; no doubt it is joined to organic substances. Tests for oxalate and fluoride gave negative results.

S. WALDBOTT.

Ferment-antiferment balance of the serum. J. W. JOBLING, WILLIAM F. PETERSEN AND A. A. EGGSTEIN. Vanderbilt Univ. *J. Lab. Clin. Med.* 1, 172-80(1915).—Review of the literature, with special reference to the work from the authors' lab. on the nature of the normal antiferment of serum. They consider it to be related to the lipoidal constituents. H. G. W.

Effect of hemolytic drugs, toxins and anti-sera upon the hemolytic point (so-called isotonic point), and the association between this point and hemoglobinuria. S. R. CHRISTOPHERS AND K. R. K. IVENGAR. Kasauli. *Indian J. Med. Research* 3, 232-50(1915).—KClO₄, PhOH, Na glycocholate, Na taurocholate, quinine, diphtheria toxin and pyocyanus toxin neither induce hemoglobinuria nor have any effect upon the hemolytic point. Those substances which cause hemoglobinuria (pyrogallol acid, abrin and hemolytic serum) raise the hemolytic point. Hemoglobinuria does not occur until the hemolytic point is raised to 0.9. Cobra and daboia venoms raised the hemolytic point, but probably produced death before the onset of hemoglobinuria. C. J. WESR.

Pathological effects of atmospheres rich in oxygen. HOWARD T. KARSNER. Boston and Cleveland. *J. Exp. Med.* 23, 149-70(1916).—Atms. containing 80 to 96% O under normal pressure produce in 24 hrs., or more commonly in 48 hrs., congestion, edema, epithelial degeneration and desquamation, fibrin formation and finally a pneumonia, probably of irritative origin and to be described as a fibrinous bronchopneumonia. Although deficiency in O may affect the hematopoietic system, the animals subjected to high O percentages failed to show any demonstrable pathologic changes in blood, spleen, lymph, nodes, or bone marrow, except for the presence of congestion. C. J. WESR.

"Acetone bodies" in diabetes mellitus. JACOB ROSENBLOOM. Pittsburgh. *J. Am. Med. Assoc.* 65, 1715-7(1915).—Five cases were studied for 6, 8, 10, 10, and 12 day periods, respectively. The standard strict diets of van Noorden were used, with increased amts. of protein always given as meat. The protein, fat, and carbohydrate intake was measured, and the glucose, acetone, acetoacetic acid, and β -hydroxybutyric acid output was detd. All 5 cases show a marked increase in the amts. of the "acetone bodies" when the protein intake was increased; and a decrease in the excretion of "acetone bodies" when the protein intake was diminished. R. attributes the increase of acetone, etc., following an increased protein intake, to the fact that some of the amino acids in the protein, notably leucine, tyrosine, and phenylalanine, act as ketogenic substances. This agrees with the work of Moorhouse, *et al.* (cf. *C. A.* 9, 1800) wherein the substitution of gelatin (which is low in leucine and phenylalanine, tyrosine being absent) in place of meat, produced a marked diminution in the excretion of "acetone bodies." Three tables and 43 references, mostly recent, are given. L. W. RIGGS.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Experimental study of the biochemical and therapeutic action of colloidal mercuric sulfide employed intravenously. M. QUATTRINI. *Lo sperimentale* 69, 507-22(1915).—The amts. injected (in rabbits) were from 0.0117 to 0.25 g. HgS in vols. of 2, 5, and 25 cc. The HgS after injection changed its physical state in a few mins., becoming a fine granular suspension. The therapeutic effect in syphilitic rabbits is slight; in fact there is none while the scrotal lesion is in its period of increase. Healing, however, is accelerated by HgS during the regressive period of the lesion. HgS is most efficient in cases in which the lesions are situated in organs (spleen, liver, bone-marrow, and lungs) which have a particularly noticeable power of fixation of the HgS. H. W. B.

The absorption of potassium iodide by perfused thyroid glands and some of the factors modifying it. DAVID MARINZ AND H. O. FRISS. Cleveland. *J. Pharmacol.*

7, 557-76(1915).—The object of this work was to ascertain if surviving thyroid cells *in vitro* possess a specific affinity for I similarly to thyroid cells *in vivo*. A special perfusion app. is described. The thyroid perfusion effects were compared with those on the kidney and spleen. It was found that artificially perfused thyroids absorb and retain KI to the same extent as thyroids perfused *in vivo*, but not the perfused kidney and spleen. The absorption and retention of KI are characteristic of the living cells as judged by O consumption and histological structure. Dead cells, as indicated by desquamation of alveolar epithelium, did not absorb as much I as the living cells. Absorption is independent of the concn. of KI. It is inhibited by KCN, probably because enough was used to cause death of cells. The effects of such ions as Br, SCN and NO₂ in this direction were not studied. Small amounts of stored iodothyroglobulin could be washed out from surviving glands and very large amts. from dying glands. The fact that no I was detected in the fluid surrounding the perfused organ, despite the fact that the lymphatic vessels drained directly into it, strongly suggests that iodothyroglobulin is given up directly to the blood stream. Autolyzing glands did not absorb KI; they rapidly give up their stored I to the perfusate. The KI stored in a thyroid from 1 hr. perfusion, whether *in vivo* or *in vitro*, was pharmacologically inactive, as indicated by the tadpole test of Gudernatsch (*Arch. Entwickl.-physiol.* 1912, 25, 457).
P. J. HANZLIK.

Contributions to the physiology of the stomach. XXVIII. Further studies on the action of bitter tonics on the secretion of gastric juice. LOUIS D. MOORHEAD. Chicago. *J. Pharmacol.* 7, 577-89(1915).—The following bitters, tinctures of gentian and calumba, and elixir of iron quinine and strychnine were administered to dogs (normal and cachectic) in the mouth and into the stomach (Pavlov-pouch) in order to ascertain what effects, if any, are produced on the appetite and quantity and quality of gastric secretion. Acting either in the mouth or stomach of normal dogs, these bitters had no appreciable influence on either the appetite or the gastric secretion; acting in the mouths of cachectic animals, there was a favorable influence. Although these effects are not quite equivalent to normal, yet they are definite and worthy of note, indicating that the use of bitter tonics in medicine is not without a certain amount of material foundation. Acting in the stomach of cachectic animals, the bitters had no appreciable influence on the quantity and quality of gastric secretion.
P. J. HANZLIK.

The central action of digitalis as tested by the cardio-inhibitory center. C. W. GREENE AND J. O. PRELER. Columbia, Mo. *J. Pharmacol.* 7, 591-9(1915).—An attempt was made more definitely to analyze the action of digitalis (Mallinckrodt's sol.) on the nervous center of the cardio-inhibitory pathway by perfusion of the isolated head and brain of the turtle. The results obtained were strong and direct stimulation of the cardio-inhibitory center; paralysis of the center by excessive action as indicated by escapement of the heart during perfusion and failure of subsequent perfusions to produce inhibition; cumulative and persistent action as indicated by recurrence of various degrees of inhibition during subsequent perfusion. Besides inhibition of rhythm there was also a blocking of the passage of the contraction wave from the veins and sinus to the ventricle by a decrease in conduct.
P. J. HANZLIK.

The influence of some drugs used in the treatment of gout (and arthritis) on the elimination of uric acid and other waste products from the blood. W. DENIS. Boston. *J. Pharmacol.* 7, 601-12(1915).—Subjects convalescing from various diseases, other than gout, and on purine-free diet were used. BzOH (8 g. per day) increased the uric acid excretion in urine and decreased the uric acid content of the blood. Other drugs which were tried, cinnamic acid (4 to 6 g. per day), quinic acid, wine of colchicum and *p*-(HO)C₆H₄CO₂H, had little or no effect on the urinary or blood uric acid. None of the drugs produced any change in the non-protein N of the blood. No effect on

the creatine content of the blood was observed with BzOH, aspirin and atophan. Cf. *C. A.* 9, 3299. P. J. HANZLIK.

Fatal veronal poisoning. F. HUSEMANN. *Vierteljahreschr. ger. Med. öffent. Sanitätsw.* 50, 43-59(1915).—A general treatment of the subject in which the pharmacology and histology of the tissues are considered. EDWARD J. KELLEY.

Quantitative study of cutaneous analgesia produced by various opium alkaloids. DAVID I. MACHT, N. B. HERMAN AND CHAS. S. LEVY. *Proc. Nat. Acad. Sci.* 1, 582-5 (1915).—Finely graded pain sensations were produced on various surfaces of the body by fine electrodes attached to a graduated inductorium. In this way normal threshold values were first obtained for the hand, nose, lip, and tongue, and results were expressed in C. G. S., or electrical units. Opium alkaloids were then injected and a rise or fall of the sensory threshold noted. Beginning with the strongest the following substances are given in the order of analgesic efficiency: morphine (10 mg.), papaverine (40 mg.), codeine (20 mg.), and narcotine (30 mg.). Narceine and thebaine raised the sensory threshold. A combination of morphine with narcotine exhibited a synergistic potentiation, *i. e.*, a much greater analgesia was produced than could be explained by the arithmetical sum of the constituents (cf. Straub, *C. A.* 6, 2651). The same was true of Sahli's prepn. (a combination of total opium alkaloids). Also in *J. Pharmacol.* 8, 1-37 (1916). D. I. MACHT.

Arterial pressure and diuresis in hypophysis therapy. A. FARINI AND B. CECCARONI. Padua. *Clin. med. ital.* 52, 497-513; *Zentr. Biochem. Biophys.* 18, 110(1915).—Exts. of the posterior lobe of the hypophysis have the property of increasing diuresis and diminishing the max. of arterial pressure (approx. 10-20 mm. Hg). Minimal blood pressure remains practically unchanged so that a reduction of the differential pressure which depends primarily upon a decrease in maximal arterial pressure corresponds to the greatest amt. of urine. This behavior is exactly the opposite of that which is known regarding the diuretic action of digitalis. The pituitrin of Parke-Davis was found to be more active than the hypophysin of Merck; the diuretic action is especially pronounced in oliguria and, since the prepn. does not increase the max. of arterial pressure, it may be administered in cases of hypertension. The diuretic action of hypophysis ext. probably depends on a direct stimulation of the excretory mechanism of the kidney. H. S. PAINE.

Iodine and sodium hypochlorite as wound disinfectants. HARRY A. SCHÜTZE. *Brit. Med. J.* 1915, II, 921-2.—Tables are given showing comparative activities of I, C_6H_6 , and Dakin's soln. against staphylococci and spores of *B. edematis maligni*. A. H. RAHE.

The use of quinine hydrochloride solution as a dressing for infected wounds. KENNETH TAYLOR. *Brit. Med. J.* 1915, II, 923-4.—When employed in wound treatment in 1% soln., quinine-HCl is not pptd. by the serum present. Expts. *in vitro* show that at this strength the bactericidal activity of the compd. is not markedly diminished. A. H. RAHE.

Inhibition of the toxicity of uranium nitrate by sodium carbonate, and the protection of the kidney acutely nephropathic from uranium from the toxic action of an anesthetic by sodium carbonate. WILLIAM DEB. MACNIDER. Univ. North Carolina. *J. Exp. Med.* 23, 171-87(1916).—The toxicity of uranium in animals of different ages is associated with the power of the metal to lead to the formation of organic acids, such as acetoacetic acid, and acetone. The power of Na_2CO_3 to lessen the toxicity of uranium depends upon its power to delay the formation of such bodies and to cause their appearance in the urine in lessened amts., and is not due to any detoxicating action of the carbonate on the metal. The protection of the kidney by Na_2CO_3 is probably

dependent upon 2 factors: the neutralization of org. acids formed prior to and during the anesthesia and the neutralization of HCl which Graham has shown to be liberated by CHCl_3 during an anesthesia induced by this substance. C. J. WEST.

The salicylates. I. A historical and critical review of the literature. PAUL J. HANZLIK. Cleveland. Therapeutic Research Committee of the Council on Pharmacy and Chemistry of the Am. Med. Assoc., *Annual Rept.* 1914, 55 pp.—A very comprehensive review, with references, of the salicylates, their chemistry, pharmacological actions, actions under clinical conditions, modes of administration, and a summary indicating various phases still needful of scientific investigation. E. J. C.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Chemical hygiene. C. H. KETNER. *Chem. Weekblad* 12, 1071-6(1915).—A discussion of some analytical methods in use by the Dutch municipal food laboratories. J. T. FLOHL.

Some bacteriological problems arising under food and drugs act. GEORGE W. STILES. *Am. Food J.* 10, 469-72(1915).—S. reports bacteriological examn. of over 1,200 samples of food products, bottled water, etc., at the Denver, Colorado, laboratory of the Western Food Inspection District of the U. S., and gives a general discussion of bacteriological problems, and their application to the public health, in connection with milk, butter, cheese, condensed milk and other dairy products; candy, dried and frozen eggs, oysters, raw vegetables, bottled water, etc. The paper includes many references to the literature. G. A. MENGE.

Some phases of the citrus by-products industry in California. R. T. WILL. *J. Ind. Eng. Chem.* 8, 78-86(1915).—A discussion of the need for an industry in Calif. that will utilize the cull citrus fruit, with a brief sketch of various attempts that have been made to produce citrus by-products on a paying basis. The different possible products, such as lemon and orange juices, marmalades, citrus oils, candied peel, fruit sirups, and citric acid, are treated in detail. H. S. BAILEY.

Composition of frozen oranges and lemons. H. D. YOUNG. *J. Ind. Eng. Chem.* 7, 1038-41(1915).—Analyses of samples of frozen and unfrozen navel oranges and Eureka lemons. The samples comprized fruit which had been freshly picked and that which had been stored. The following detns. were made: sp. gr. of the fruit and juice, % total and invert sugar, and % acid in juice and g. of sugar per fruit. P. J. D.

Analysis of English malt vinegar. HANS FOERSTER. *Deut. Essigind.* 19, 149-50 (1915); *Chem. Zentr.* 1915, II, 370.—Results of analysis of malt vinegar carried out according to directions in "Aids to the Analysis of Foods and Drugs," by Moor and Partridge. E. H.

Examination of cocoa. KELLER. *Apoth. Ztg.* 30, 560-1(1915).—The article deals with the detn. of shells in cocoa and its products, recourse being had to a microscopical examn. for the possible detection of large spiral organs present in the shell tissue. W. O. E.

Examination of cocoa. T. F. HANAUSEK. *Apoth. Ztg.* 30, 590-1(1915).—Reference is had to the article by Keller (cf. preceding abstract). W. O. E.

Effect of storage on coffee. R. E. DOOLITTLE AND B. B. WRIGHT. *Am. Food J.* 10, 473-4(1915).—*See C. A.* 10, 226. G. A. MENGE.

Coffee. CHARLES. *Repert. pharm.* 27, 293-5(1915).—As a result from Belgium and northern France has been cut off.

Chicory has come to be very generally used among all classes of people not only to fortify the flavor of coffee but also as a separate and distinct flavor. It was thought that at this time other roots might be substituted for chicory. Examn. of a large number of samples did not reveal any such adulteration. Some of the samples showed much more caramel than others. If sugar is a natural constituent of chicory this caramel could be accounted for by variations in the roasting. If chicory root be macerated with water and allowed to stand 24 hrs., an alc. fermentation takes place with an abundant evolution of CO_2 . An aq. soln. of raw chicory gives a strong rotation to the left, due to inulin and sugar. As the root is subjected to increasing intensities of roasting this rotation gradually diminishes and becomes slightly positive. As roasting approaches complete caramelization the dextro rotation approaches zero. This behavior shows the presence of dextrose and sucrose. Chem. analysis revealed as much as 40% sucrose and 10% of dextrose in some varieties of raw chicory. The amt. of sugars found varied with the soil, species, environment, etc. H. R. SMITH.

Non-alcoholic carbonated beverages. Sanitary condition and composition. R. M. ALLEN, J. O. LABACH, W. R. PINNELL AND L. A. BROWN. Kentucky Agr. Expt. Sta., *Bull.* 192, 59-125(1915).—The first part of the bulletin deals primarily with the sanitary side, along with inspection and control work. The second part deals with the chem. examn. of pops. Pops are defined as "non-alcoholic, artificially carbonated beverages, sold in the original bottles, and intended to be consumed as soon as opened." They are sweetened and flavored and colored to imitate some fruit. A discussion of flavoring principles as well as the colors employed is given. Part III deals with bacteriological data. B. E. BROWN.

Short notes from practice. L. KALUSKY. *Z. Nahr.-Genussm.* 30, 337-8(1915).—*Glycerol detns. in wine according to Rothenfusser*: K. uses a Gooch crucible for filtering the ppt. of CaC_2O_4 obtained in the Rothenfusser procedure (*C. A.* 6, 2132), the asbestos of which the filter pad is prepd. having previously been treated with hot H_2SO_4 of the same strength as that used for the final soln. of the CaC_2O_4 and then thoroughly washed. The CaC_2O_4 is washed upon the Gooch; the filter pad and its contents are then introduced into a beaker to which is added half the usual amt. of dil. H_2SO_4 , the acid being first used to rinse the crucible. Boil for 1 min., filter through a new Gooch, wash with the remaining half of dil. H_2SO_4 , then with hot water, and titrate the filtrate as usual. *The microscopical analysis of cocoa, chocolate, tea and coffee*: Rub up 1 g. of the substance (3 g. of sweet chocolate) in a porcelain dish with 20 cc. of hot water, then add 40 cc. of 5% KOH soln. and allow to digest for $\frac{1}{2}$ hr. with frequent stirring on a steam bath. Allow to stand until the solid matter settles, decant the supernatant liquid and wash the residue with 500 cc. portions of hot water by decantation until the washings are practically colorless. Finally decant as much as possible of the liquid and drain the residue by gentle suction on a paper disk within a Gooch crucible. Sep. the material from the paper and soak for 24 hrs. in a satd. chloral hydrate soln. containing a little glycerol. This treatment clears the tissues so that they are easily recognized under a microscope. In the case of ground coffee preps. it is well also to digest a little of the sample for 2-3 hrs. in water on a steam bath, replacing the water as it evaps. The coarse pieces of coffee can then be picked out and after shredding and mounting in chloral hydrate may readily be recognized under the microscope. A. F. SEEGER.

The determination of moisture in sirups by the calcium carbide method. R. M. WEST. *J. Ind. Eng. Chem.* 8, 31-5(1916).—Expts. with a modified McNeil app. (*C. A.* 6, 2120) for the detn. of H_2O by the CaC_2 method lead to the conclusion that on sirups it is accurate within 0.3-0.4%, and equal to the A. O. A. C. method. The CaC_2 method gives a sharp end point, is more rapid than the A. O. A. C. method, and

can be used when acids are present in fruit juices by correcting the vol. of C_2H_2 for total acidity. It is necessary to run a blank on each batch of CaC_2 to detn. its H_2O equiv.

H. S. BAILEY.

Estimation of moisture in dried fruits. H. E. BARNARD. *Am. Food J.* 10, 474 (1915).

—B. briefly discusses the published work of previous investigators in this field. It is recommended that a number of methods heretofore used be discarded as impractical. Commercial New York State evapd. apples were used. Twenty g. of the sample were passed twice through a meat grinder using a fine cutter. Material thus prepd. was applied in 10 sets of expts., the essential technic for drying in each set being as follows: (1) in a current of H in special tubes at 98° ; (2) in special tubes without H, at 98° ; (3) in open dishes on steam bath, at 98° ; (4) rubbed up with hot water, open dishes, steam bath, 98° ; (5) same as (4) except rubbed with alc.; (6) same as (4) except rubbed with amyl alc.; (7) same as (4) except rubbed with satd. NaCl soln.; (8) in open dishes at 23 inches Hg and 70° ; (9) same as (8) except at 72° ; (10) same as (9) except for use of glass-stoppered weighing bottles. The results are plotted on a chart showing time as abscissa in hours from 0 to 20, and loss of moisture as ordinate from 11 to 26%. Drying *in vacuo* at 70° gives lower but more concordant results than the other methods employed.

G. A. MENGE.

Effect of storage on moisture content of cloves. A. W. OGDEN. *Am. Food J.* 10, 474 (1915); see C. A. 10, 90.

G. A. MENGE.

Determination of bitter almonds in sweet almonds. A. F. SEEKER. *Am. Food J.* 10, 474 (1915).—The method of tasting, usually applied among dealers, is not adequate when many samples are involved. A simple application of the Schönbein test is recommended as a rapid method: Sat. a strip of filter paper (similar to C. S. & S. No. 597) with a 10% ext. in 95% alc., of freshly powdered guaiac rosin and allow to dry spontaneously. Immediately before applying the test sat. the paper with $CuSO_4$ soln. (1–10,000) and spread upon a glass or porcelain plate. Take 100 almonds from the sample, cut each in two so as to furnish a smooth cut surface and place one piece of each almond on the wet sensitized paper so as to obtain close contact between the cut surface and the paper. In a few minutes the bitter almonds will show a deep blue stain on the paper while the sweet almonds are without effect. This test compared with the taste test gave identical results. The test does not apply to blanched almonds. These must still be tested by taste.

G. A. MENGE.

Some notes on the examination of saffron. J. F. DARLING. *Am. Food J.* 10, 468–9 (1915).—D. gives a brief botanical description of the flower of the crocus plant, the source of saffron of commerce. The plant has been cultivated for centuries in Europe and Asia Minor. The principal sources of importations to the United States are France, Spain and, in small amounts, Turkey. The yield of dry saffron per acre is about 33 to 36 pounds and the consequent high cost is conducive to adulteration. Methods of applying and detecting adulteration are briefly discussed. Methods of analysis include: (1) Examn. as to identity, (2) moisture and ash, (3) character of stain on filter paper, (4) water-sol. content, (5) sugars, (6) glycerol, (7) NH_4 salts. Saffrons of good quality should conform approx. to the following analytical values: Yellow tissue attached to stigmas 8, moisture 15, ash (dry basis) 6–8, petroleum-ether ext. 1.5, non-volatile ext. (dry basis) 1.1, and water-sol. content (dry basis) 55–65%; the limit for sugars has not been definitely detd. Corresponding data obtained by examn. of 43 samples from Spain, 22 samples from France and 5 samples from Turkey, presented for entry into the United States, are tabulated.

G. A. MENGE.

The banana and its by-products. E. COLLIN. *Ann. fals.* 8, 280–91 (1915).—A botanical and histological description of several varieties of banana, with microscopic drawings, followed by a brief discussion of banana starch and flour. Cuts showing

the microscopic characteristics of these products, and tabulated chem. analyses of banana products and other flours and starches, are given. When the calorific food value and the cost of banana flour are compared with those of other farinaceous foods, it appears to be a very expensive diet.

H. S. BAILEY.

The carbohydrates and the enzymes of the soy bean. J. P. STREET AND E. M. BAILEY. *J. Ind. Eng. Chem.* 7, 853-8(1915).—The soy bean is especially suitable for food for the diabetic, because it is rich in protein and fat and contains only traces of starch. The EtOH and cold water exts. were examd. for sugars and digestions of the soy meal, after extn. with Et₂O and boiling EtOH, made with malt ext. The cell constituents, crude and true cellulose, galactans, and pentosans, and their distribution were detd. A study of the enzymes leads to the conclusion that in addition to urease, amylase, and glucoside-splitting enzymes previously reported, there is also present in soy beans a protease of the peptoclastic type, a peroxidase and a lipase. No sucrase nor protease of the peptonizing type was obtained.

H. S. BAILEY.

The milling of rice and its mechanical and chemical effect upon the grain. F. B. WISE AND A. W. BROOMELL. U. S. Dept. Agr., *Bull.* 330, 31 pp.(1915).—The paper describes the milling processes and machinery employed, and considers each operation in the light of its effect on the chem. and mechanical qualities of the finished products. During the process of milling the rice grain, the hull, the germ, 6 of the bran layers, and a portion of the 7th are removed. Approx. 10% of the wt. of the kernels is lost by removal of the germ and bran coat. In the modern mill the brown or hulled rice loses about 70% of its ash, 85% of its fat or oil, 70% of its crude fiber, 10% of its protein, and 30% of its pentosans, due to the removal of germ and bran coats. The mill yield of rice hulls approximates 30 lbs. of rice hulls, 20 lbs. of rice bran, and 6 lbs. of rice polish per bbl. of rough rice. Bran and polish are rich in fat and protein, and when fresh and not adulterated with hulls are considered an excellent stock feed.

P. B. DUNBAR.

A method for the determination of the strength and baking qualities of wheat flour. C. H. BAILEY. *J. Ind. Eng. Chem.* 8, 53-7(1916).—"The strength of a flour is detd. by the ratio between the rate of production of CO₂ in, and the rate of loss of CO₂ from, the fermenting mass of dough." In baking tests, as ordinarily made, the element of personal judgment enters to a large extent. Details of proposed empirical methods which will tend to place such tests on a more scientific basis are given, and a simple "Expansimeter" which automatically records the max. expansion of the dough is described.

H. S. BAILEY.

Preservation of Indian meal. A. MARBACH. *Oesterr. Chem. Ztg.* 18, 96(1915).—Indian meal can be preserved best by germination previous to milling. It thus loses its specific taste. Maize oil and the oil cake are the by-products. The first is valuable in the manufacture of soap, the latter as a cattle feed.

ARTHUR LEDERER.

A biochemical reaction for rancid fats. I. VINTILESCU AND A. POPESCU. *Bull. acad. sci. roumaine* 4, 151-7(1915); *J. pharm. chim.* 12, 318-23(1915).—By mixing 10 g. fat which had been exposed to the air several hrs., with 4-5 drops dil. blood or hemoglobin, 10 drops tinct. guaiac and 10 cc. H₂O, the mixt. is colored blue. Fresh fat does not give this reaction. Other oxidizable substances like benzidine and guaiacol may be substituted for guaiac but the test is not so good. V. and P. have not been able to detect an oxidizing ferment either in fresh or rancid fat. They therefore conclude that the rancidity of fats (lard, butter, olive oil, almond oil) is due to the presence of some substance which on exposure to air fixes oxygen. This in turn can be released by peroxidases.

L. H. CHERNOFF

Effect of time upon optical rotation of lemon oil. A. F. SEEKER. *Am. Food J.* 10, 466(1915).—Six samples of lemon oil, representing composites of several oils pro-

duced, under the supervision of the U. S. Department of Agriculture, in the 6 principal producing districts of Sicily, were collected during the winter of 1907-8. They were stored in small coppers, partly filled and tightly closed with cork stoppers but not sealed, in a refrigerator which, except at rare intervals, contained ice. When examined in 1915, the samples had a pronounced turpentine-like odor but could still be used as an inferior lemon flavor. $[\alpha]_D^{20}$ in 1908 and 1915, resp., are as follows: (1) 64.92°, 54.92°; (2) 61.53°, 61.63°; (3) 63.33°, 63.16°; (4) 59.58°, 59.58°; (5) 58.30°, 58.06°; (6) 62.22°, 62.01°.

G. A. MENGE.

Recent advances relating to the composition and analysis of edible oils and fats. E. RICHARDS BOLTON AND CECIL REVIS. *Analyst* 40, 494-503(1915).—A review.

P. B. DUNBAR.

The determination of citric acid in milk. R. KUNZ. *Arch. Chem. Mikros.* 8, 129-33(1915).—Using the pentabromoacetone method previously described (*C. A.* 9, 587), with slight modifications, K. detd. the quantity of citric acid in various milks. The market milks of Vienna (4 samples) contained from 0.1553 to 0.1730 g. per 100 cc., 2 samples of human milk gave 0.0618 g. and 0.0439 g. The first of a milking from one cow ran 0.1980 g., that taken during the middle of the milking, 0.1992 g., and the strippings, 0.1806 g. of citric acid per 100 cc. Upon standing 24 hrs., the citric acid content of 1 sample of market milk fell from 0.1707 g. to 0.1206 g. and in a second from 0.1571 to 0.0915. After 48 hrs. neither sample contained any citric acid. When 1 cc. of toluene was added to 100 cc. of fresh milk the citric acid content did not change during 2 days. Bulgarian sour milk (Yoghurt) showed no diminution in citric acid, even after 3 days. The difference between natural souring and that in Bulgarian sour milk needs further investigation.

H. S. BAILEY.

Cheese examination and guarantee of fat content in dry substance of cheese. S. TIJMSMA AND M. KAUFMANN. *Chem. Weekblad* 12, 1052-63(1915).—Method for cheese analysis suitable for rapid work in cheese control stations. Place 3 g. of cheese in the wide part of a cheese butyrometer which has previously been half filled with H_2SO_4 (1.53 sp. gr.). The butyrometer is placed in H_2O at 65-70°, and frequently shaken. When the cheese is disintegrated, 1 cc. amyl alc. is added and more H_2SO_4 up to the mark. Let stand 5 min. in warm water and whirl for 4 min. at not less than 1000 r. p. m. The fat column is read in the usual manner.

P. J. DONK.

Skimmed milk and potatoes as a meat substitute. T. PFRIFFER. *Wiener landw. Zeit.* 65, 366-7(1915).—P. states that 4.5 l. of skimmed milk and 1.1 kg. of potatoes have the same protein content and calorific value as 1 kg. of beef which costs about three times as much. Figures are given to show the saving of meat which can be realized in Germany through the use of this substitute.

C. F. MILLER.

The determination of sucrose in condensed milk. G. W. KNIGHT AND G. FORLANEK. *J. Ind. Eng. Chem.* 8, 28-31(1916).—A review of previous work upon the detn. of sucrose in condensed milk, and the details of a new method are given. Phosphotungstic acid and $Pb(OAc)_2$ are used as clarifying agents, the excess of Pb being removed by $K_2C_2O_4$. The % of sucrose is calcd. from the direct polarization and the tading taken after inversion with HCl in the cold for 8 hrs.

H. S. BAILEY.

Salted market milk. F. REISS. *Z. Nahr.-Genussm.* 30, 333-4(1915).—A milk containing 2.75% fat and showing evidence of having been watered, also gave a nitrate reaction and was found to contain 1.23% NaCl. The peculiar sophistication of this product was found to have been caused by a leak in the brine pipes used for cooling the contents of a stock tank at the dairy.

A. F. SEEGER.

The persistence of hydrogen peroxide in milk. E. HINKS. *Analyst* 40, 482-91(1915).—The length of time during which H_2O_2 persisted in milks was studied, using

varying concn. of H_2O_2 , varying temp., and fresh and old milks. It was found that the H_2O_2 was destroyed rapidly at first, but that the rate of destruction diminished, and if the concn. of H_2O_2 was high enough to withstand the first rapid destruction, the residual H_2O_2 remained const. over long periods. In fresh milk the proportion of H_2O_2 destroyed was much less than in the same milk which had stood for 3 days, and consequently possessed a higher catalytic activity. In general a rise in temp. lengthens the time during which H_2O_2 persists. The ultimate result is due in every case to the resultant of destructive effects of catalase on H_2O_2 , and of H_2O_2 on catalase. $o\text{-HOC}_6\text{H}_7\text{NHMe.H}_2\text{SO}_4$, benzidine and $p\text{-C}_6\text{H}_4(\text{NH}_2)_2$ have all been used for the detection of H_2O_2 in milk. The last named is on the whole most generally applicable. The reaction depends upon the simultaneous presence in milk of H_2O_2 and a peroxidase. Owing to the destruction of the latter by H_2O_2 , it is necessary when testing for H_2O_2 to add some fresh milk as well as the reagent used to insure the presence of peroxidase. Under certain conditions a milk containing H_2O_2 and a heated milk will react in exactly the same manner.

P. B. DUNBAR.

Serological detection of potatoes and potato preparations. A contribution to the knowledge of precipitant serums. D. SCHENK AND H. BURMEISTER. *Z. Natur.-Genussm.* 30, 325-32 (1915); cf. *C. A.* 9, 2112.—A specific anti-serum for potato protein was prepd. by filling an Erlenmeyer flask to the brim with freshly grated potatoes to which a few drops of phenol had been added, allowing to stand for 24 hrs., decanting the juice, filtering and then centrifuging until perfectly clear, the clarified product being injected into rabbits in 5 cc. portions repeated every 5-6 days until each animal had received 30 cc. A serum prepd. from the blood of the rabbits produced a ppt. when added to a dil. ext. of potatoes prepd. with physiological salt soln. Exts. of barley, oats, wheat and rye prepd. in a similar way did not react with the serum. This serum can be used only in the case of unheated potato preps., products like bread containing potato flour giving no reaction. Following the general plan adopted by Schmidt (*C. A.* 6, 2108) in the case of cooked meat, S. and B. also prepd. an anti-serum applicable to heated potato products as follows: Grate well cleaned and scraped potatoes in such a way that the pulp falls into a sufficient quantity of physiological salt soln. to prevent discoloration of the paste by oxidation changes. Strain the pulpy mass, filter the strained liquor, acidify the filtrate slightly with a few drops of dil. HCl, and heat at 70° until no more protein is pptd. Allow the ppt. to settle and wash with water by decantation until the washings show only a slight HCl reaction. Drain the ppt. as free from water as possible, add a few drops of 10% NaOH, and heat at 70° until a clear yellowish soln. is produced. Dialyze in a parchment cell until the protein soln. is only slightly alk. to litmus (12-48 hrs.). Preserve the soln. by adding a few drops of phenol and keeping in a refrigerator. The soln. used by S. and B. contained 17.06 g. of protein ($N \times 6.25$) per l. Prep. the anti-serum from the blood of rabbits injected with this soln. as described above. Test the anti-serum against the soln. used for injection by dilg. the latter with physiological salt soln. until it yields only a weak biuret reaction. The weakest of the serums prepd. by S. and B. gave a reaction in 20 min. when applied to the heated alkali-protein soln. dild. 0.1 cc. to 100 cc., 0.1 cc. of the serum being added to 1 cc. of the dild. protein. The serum does not react with solns. of heated cereal proteins prepd. in the same manner. In order to test bread or similar products by this method proceed as follows: Treat 10 g. of finely divided bread in a 100 cc. Erlenmeyer flask with 1.5% alc. NaOH and heat on a water bath under a reflux condenser to 70° allowing the flask to remain at this temp. for 10 min. Filter while warm, dil. with an equal vol. of water and neutralize with HCl until only slightly alk. to litmus. Add 2-3 cc. of 7% $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ which should render the mixt. slightly acid to litmus. Introduce into a separatory funnel and shake with ether to remove

fatty acids. Allow to sep. and remove most of the aq. layer through the stopcock allowing the liquid to flow upon a filter. Decant the clear ether layer, and reject. Shake the residue of protein once more with ether, allow the layers to sep., and then run the layer containing the suspended protein upon the filter, wash with water, place the filter and its contents in a beaker, moisten with a few drops of 0.1 N NaOH, add a little water, filter through a double filter into a parchment cell, and dialyze until there is only a slightly alk. reaction with litmus. Dilute the alkali-protein soln. with physiological salt soln. and test with the anti-serum as described above. Bread containing as little as 10% of boiled potatoes gives a distinct reaction, whereas in the case of those prepd. from pure cereals the reaction is negative. A. F. SEEKER.

Examination of scallops. A. L. SULLIVAN. *Am. Food J.* 10, 472-3 (1915).—The edible portion, which consists only of the muscle by which the scallop opens and closes its shell, constitutes about 17% by weight of the scallop. They are a valuable food product, containing 19 to 24% of solids and 12.6 to 15.6% of protein. A fraudulent and usually unsanitary practice in the industry consists in soaking the scallops in fresh water overnight, the effect of which is to increase the size and otherwise produce an appearance of superiority. By this treatment $4\frac{1}{2}$ gallons of fresh scallops will swell enough to fill a 7 gallon keg. Under methods of analysis S. briefly discusses the values to be detd., the most important of which are detns. of solids, protein and ash. Analytical data for 31 samples of unsoaked, and for 12 samples of soaked, scallops are included in a table. The range for the important factors are: For the unsoaked samples, solids 19.21-24.17, av. 22.48%; protein 12.62-15.69, av. 14.38%; ash 1.33-1.81, av. 1.56%; the corresponding values for the soaked samples are 14.18-19.64, av. 16.20%; 9.06-11.80, av. 10.57%; 0.93-1.17, av. 1.02%. G. A. MENGE.

Method of desiccating milk or other liquid. G. A. KRAUSE. U. S., 1,166,225, Dec. 28. The liquids are sprayed into a dehydrating gas current.

Apparatus for sterilizing milk by ultraviolet rays. M. VON RECKLINGHAUSEN. U. S., 1,165,921, Dec. 28.

Meat extracts. H. WATKINS-PITCHFORD. *Brit.*, 19,087, Aug. 26, 1914. Meat exts. prepd. as specified in 19,431, 1912 (*C. A.* 8, 539) are mixed with excipients such as glycerol, liquid paraffin, or vegetable oils, which render them palatable and stable. The mixt. may be further concd. to remove all the H_2O , and then mixed with cod-liver oil, with or without malt ext., etc. It may also be mixed with milk, grape juice, wine, brandy, stout, etc., or made into jujubes, etc.

Meat extract. H. WATKINS-PITCHFORD. U. S., 1,165,924, Dec. 28. A highly-flavored meat ext. is prepd. by roasting slices of meat, scraping off the browned superficial portions, extg. the remaining portion with warm H_2O , evapg. the ext. thus formed *in vacuo* and mixing this concd. ext. together with an ext. prepd. from additional fresh meat with the browned portion previously sepd. The ext. of fresh meat may be predigested if desired by treatment with pawpaw juice.

Predigested meat product. H. WATKINS-PITCHFORD. U. S., 1,165,925, Dec. 28. Lean meat is treated with warm H_2O to dissolve out salts and extractives and then is digested with pepsin, papain or pawpaw juice. The digested product is boiled and filtered, mixed with glycerol or bland oils and the mixt. is concd. *in vacuo* to drive off the H_2O .

Granulated meat product. C. MARCHAND. U. S., 1,167,193, Jan. 4. Meat pulp is macerated with dil. HCl at a temp. of about 25° until a gelatinous mass is formed. This is neutralized, treated with H_2O_2 to prevent decompn., heated to 40° to melt the fat, the latter and moisture are removed by skimming and centrifuging and the residue is dried and granulated.

Extracting grape pomace. E. MONTI. U. S., 1,167,006, Jan. 4. Crushed, pressed grape pomace is soaked in H_2O at a temp. of $50-60^\circ$ until thoroughly extd., the liquid is pressed out and strained and then used to ext. another portion of the pomace, cooled to 0° and concd. by freezing or evapn. *in vacuo* until an ext. is obtained containing 66-80% of sugar and other solids.

Preserving fruit. A. F. HOFFMAN. U. S., 1,166,588, Jan. 4. Fruit is chilled in H_2O of a temp. near 0° , sterilized by ultraviolet rays and then coated with wax, applied at a temp. of $100-105^\circ$.

Pineapple waste. R. A. GOULD and C. S. ASH. U. S., 1,166,674, Jan. 4. Recovery of albumin, sugar and acid from pineapple waste is effected by pressing out and straining the juice and adding to the expressed juice an additional amt. of juice recovered by diffusion, heating the mixed juices to about 82° to coagulate the albumin. The juice is sepd. from the pptd. albumin and treated with CaO or $CaCO_3$ to form an insol. citrate (still leaving the juice with an acidity equal to 0.01 *N*). The initial ppt. of citrate is sepd. and a further ppt. produced by concn. *in vacuo* of the soln. remaining. After filtration the soln. is heated to about 70° and decolorized with charcoal and reduced to a sirup. The dried exhausted pulp is utilized as a source of cellulose.

Preserving food stuffs. CHEM. FABRIK VON HEYDEN. Ger., 285,726, Nov. 5, 1913. The preservative used is furfuracrylic acid, added to the food in soln. or not, or applied to the surface of the food. The furfuracrylic acid is said to have the advantage over cinnamic acid in that as the Na salt it does not irritate the kidneys. A mixt. of 100 g. curd and 50 cc. H_2O , to which 1.0 g. furfuracrylic acid has been added, shows no decompn. after 4-6 days nor any bad odor.

Preserving eggs. H. L. S. LOFT. Brit., 19,721, Sept. 12, 1914. Eggs are treated with vapors of a disinfectant or sterilizing agent such as $HCHO$, in air or other gas, which may contain steam, at about 35° and are then cooled to about 10° while still in the vapors. The eggs are finally coated with paraffin.

Milk containing iron and glycerophosphate. G. HÖNSCH. Ger., 285,725, Dec. 5, 1913. The product is especially suitable for anemics and children. By glycerophosphates is to be understood the salts of glycerophosphoric acid, the active substance of lecithin. From 20 to 30% of commercial Fe glycerophosphate is added to skimmed milk which is then heated, the casein pptg. out. The ppt. and the filtrate contain large amts. of Fe, about in equal proportions. Glycerophosphoric acid, however, is present in the ppt. only in traces. The excess acid in the filtrate is neutralized by Na glycerophosphate (75%). From 5 to 10% of the filtrate treated in this manner is added to the whole or skimmed milk, according as a smaller or larger content of Fe and glycerophosphates is desired. The milk does not curdle now upon heating, it has a pleasant taste, and is very stable.

Flavoring jams. A. CORDIER. Brit., 20,143, Sept. 24, 1914. An aq. ext. from apples or pears which have been pressed to make cider or perry, is sterilized and dried to obtain a flaky product which is used for flavoring jams, etc.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Determination of the electrical conductivity of Caculata water to verify its stability and chemical composition. G. A. DAMIAN. *Bull. acad. sci. roumaine* 4, 136-43 (1915).—This water contains highly ionized compds. and results of elec. cond. detns. are therefore of great interest to the chemist and from the hygienic and therapeutic standpoint. D. has detd. the elec. cond. every day for a month and has found the variations to be

exceedingly slight in spite of heavy rainfall. Chem. analyses by various investigators at various times have shown the compn. of the water to be const. The work supports the hypothesis that a direct relationship exists between elec. cond. and the compn. of a water.

L. H. CHERNOFF.

Contribution to the study of the physical properties of Roumanian mineral waters. Electrical conductivity. Applications. E. GIURGEA. *Bull. sci. acad. roumaine* 2, 171-9(1914); *Chem. Zentr.* 1915, I, 1339.—G. has detd. by the Kohlrausch method the elec. cond. of a large number of mineral waters and shows that the method affords a means of detg. the presence of waste waters or the admixt. of other waters. Similarly the degree of chem. change caused by the material of the conduit pipe may be detd. Fe or Cu pipes are often to be replaced with pipes of Al, cement, clay, or wood. The cond. enables one to follow the changes in mineral waters on warming and to det. an optimum. Results are reported and discussed.

F. W. SMITHER.

Contribution to the study of the physical properties of Roumanian mineral waters. Determination of the cryoscopic coefficient. E. GIURGEA. *Bull. sci. acad. roumaine* 2, 311-9(1914); *Chem. Zentr.* 1915, II, 47.—G. reports the results of his detns. of the cryoscopic coeff. for a number of noted Roumanian springs and discusses the significance of this work for judging the physiological action of the waters.

F. W. SMITHER.

Quantitative determination of the alkalinity of Roumanian mineral waters. E. GIURGEA. *Bull. sci. acad. roumaine* 3, 18-23(1914); *Chem. Zentr.* 1915, II, 47.—G. reports and briefly discusses results for a number of noted Roumanian springs. Method: Titrate 20 cc. of the water with 0.1 N H_2SO_4 , using methyl red as an indicator. Cf. *C. A.* 9, 3015, 3312.

F. W. SMITHER.

True object of water analysis. F. L. RECTOR. *J. Am. Water Works Assoc.* 2, 709-11(1915).—R. emphasizes the need to consider each individual water in connection with its surroundings rather than by a strict lab. standard. The U. S. Public Health Standard is criticized for ignoring the bacterial count at 20° F. and such criticism is justified by a practical example.

D. K. FRENCH.

Estimating the sanitary quality of water supplies. W. H. FROST. *J. Am. Water Works Assoc.* 2, 712-34(1915).—The subject is considered specifically from the standpoint of typhoid fever causes as typical cases. The detn. of evidence and extent of pollution in a water supply in itself is not sufficient but should be used in connection with further information as to the effect produced by a given amt. of pollution on the community. The methods of sanitary survey and examn. of water supplies with reference to their effect in causing typhoid fever are considered in detail, but the fact is emphasized that most of these results depend upon detn. of intestinal bacteria of all kinds rather than knowledge of any specific form; consequently, the necessity to det. effects produced by such pollution. In the liberal discussion which follows methods of applying the standards established for interstate carriers are considered extensively. In general, laboratory methods, both bacteriological and chemical, should be considered always with careful epidemiological studies of their relation to typhoid prevalence.

D. K. FRENCH.

The determination of alkalinity in water. F. W. BRUCKMILLER. *Chem. Eng.* 22, 231-2(1915).—Both the phenolphthalein and the methyl orange alkalinities are detd. from a single portion of water as compared with 2 portions recommended in "Standard Methods of Water Analysis" and elsewhere.

W. F. LANGELEIR.

Present status of disinfection of water supplies. F. F. LONGLEY. *J. Am. Water Works Assoc.* 2, 679-92(1915).—L. considers principally the results from the use of hypochlorite and liquid Cl in water disinfection. 80 % of the municipalities coöperating in the gathering of the information use $CaOCl_2$; the others liquid Cl. The av.

cost of treatment is about 25 cents per million gallons. Concrete tanks and wood tanks lined with concrete are used in connection with the treatment in $\frac{2}{3}$ of the cases. Concrete tanks, lead pipes and rubber compn. showed the greatest resistance to corrosion. The results from the use of hypochlorite in the reduction of typhoid death rate are itemized in about 15 typical cases. Reference is made to the objectionable odor and the quantities capable of producing this are given in several cases. Sufficient information is not at hand to establish relations between color and turbidity of the supply and the quantity of disinfecting agents that can be used without objectionable results. The discussion brings out more interesting information regarding in particular the use of hypochlorite and deals especially with odor produced. D. K. FRENCH.

Sterilization of water by carbon dioxide under pressure. H. COLIN. *Compt. rend.* 161, 652-5(1915).—A metallic cylinder of 2000 cc. capacity and capable of withstanding a pressure of 54 kg. per sq. cm. was used. One liter of water was introduced into the app. and after sterilization in an autoclave, was inoculated with 200 cc. of broth culture of the organism under investigation. CO₂ under pressure was then applied with const. shaking of the app. so that satn. of the liquid was obtained for any given pressure. The results with *B. typhosus* showed that in order to produce sterilization 20 hrs. at 10 kg., more than 8 and less than 20 hrs. at 15 kg., more than 3 and less than 9 hrs. at 20 kg. and 3 to 6 hrs. at 25 kg. pressure were required. *B. coli communis* resisted a pressure of 25 kg. for more than 5 days. *B. dysenteriae* was destroyed in less than 15 hrs. at 15 kg. and in less than 6 hrs. at 20 kg. pressure. *B. cholerae* was killed in less than 10 hrs. under 10 atmospheres. *B. pyocyaneus* under 18 kg. preserves its vitality and faculty of pigment formation for a few hours but at the end of 24 hrs. growth is slight and after 48 hrs. sterilization is complete. With *B. diphtheriae* at pressures of 10, 15 and 20 atms., sterilization was obtained after 24, 9 and 3 hrs., resp. *B. subtilis* spores resisted 25 kg. pressure for 4 days. A sample of polluted water from the Seine at 20 atms. was found to contain many putrefactive organisms after a long time but at 25 kg. pressure all organisms except *B. subtilis* were killed within a few hours. W. F. LANGELIER.

Water softening by lime and soda process. F. A. ANDERSON. *J. Soc. Chem. Ind.* 34, 1180-2(1915).—In softening water with lime and soda the detns. that are necessary are CO₂, Ca, Mg and alkalinity. CO₂ is detd. by the Seyler method. Total Ca and Mg is detd. by the Lunge-Pfeifer method. The accuracy of the method is indicated by the fact that in 13 consecutive tests, grav. detns. of Ca and Mg differed from detns. by this method by not more than 1°, the av. difference being 0.2°. Mg is detd. by A.'s modification of the Pfeifer method which is as follows: make 100 cc. of water slightly acid and conc. to about 30 cc. by boiling. Neutralize exactly to methyl orange and transfer to 100 cc. cylinder. Add 10 cc. 0.1 N NaOH, make up to 100 cc., stopper and allow to stand 2 hrs. or more. Titrate supernatant liquid. In comparative tests the following amounts of MgO in gr. per gal. were found: Gravimetric 0.93, 1.66, 1.92, 10.96; above method 0.90, 1.62, 1.95, 10.80. After treatment, the water should be tested with soap soln. and the alkalinity to phenolphthalein and methyl orange detd. If the amt. of soda added has been correct the hardness and alkalinity will be the same. If the quantity of lime added has been correct the phenolphthalein alkalinity will slightly exceed $\frac{1}{2}$ the methyl orange alkalinity. The excess OH ions are due to sol. Mg(OH)₂ and vary with the Mg salts originally present in the water. Any correction necessary in the quantities of chemicals applied can be calcd. from these simple control tests. W. F. LANGELIER.

Washing slow sand filters. J. GAUB. *J. Am. Water Works Assoc.* 2, 596-611 (1915).—Improvements in sand handling during the last few years are discussed. 1. the Blaisdell machine and the Nichols washer are described. Washing-

ton, D. C., and Springfield, Mass., use methods almost identical, the sand being removed by ejectors to sand washers, discharged into storage bins and carried by another ejector back to the filter bed. The ejectors and washers are described. Albany, N. Y., and Philadelphia, Pa., use the Nichols machine. Denver, Colo., replaces sand by cars loaded by hand owing to stratification due to high uniformity coefficient of sand. Toronto, Canada, uses portable washer. Lawrence, Mass., returns sand by hand owing to stratification due to uniformity coefficient which prevents replacement by hydraulic means. Pittsburgh uses the hydraulic method. Wilmington, Del., uses the Blaisdell machine. The cost for cleaning and replacing sand by hydraulic processes is slightly lower than the cost of cleaning by machine. The methods in practice at Washington and Springfield are the most economical of those considered. The uniformity coefficient of sand must be considered in connection with hydraulic processes.

D. K. FRENCH.

Water from gravel wells. C. W. WILES. *J. Am. Water Works Assoc.* 2, 625-8 (1915).—The paper deals largely with physical difficulties due to air leakage in the pipe lines, the suggested cause being due to the fact that the 4 in. wells in question are too small; a diam. of 8 in. to 10 in. is recommended.

D. K. FRENCH.

Design and operation of intermittently operated water purification plants. N. T. VRECH. *J. Am. Water Works Assoc.* 2, 759-61 (1915).—V. considers in particular plants where the water is retained in the basins from 4 to 6 hours. The design of the settling and coagulating basins is equally important with the operation of filters. Variation in the time of agitation, degree of mixing, with alum, lime, or lime and iron, as a coagulant, application of the chemical treatment in the basins, sedimentation, point of application of chemicals, etc., are discussed. Continuously operated plants are much more easy to handle than those of intermittent operation.

D. K. F.

Impounded waters of Alabama in relation to public health. E. B. KAY. *J. Am. Water Works Assoc.* 2, 657-78 (1915).—A very extensive and comprehensive discussion of the development of impounded waters, covering the geographical features of the drainage areas and existing knowledge regarding the physical effect of such supplies upon the fauna of the submerged area. In preliminary treatment to an investigation as to the effect of such supplies upon public health, there is a very thorough discussion of existing health conditions including malarial fevers and mosquito breeding, based upon records prior to such development. No conclusion is drawn.

D. K. FRENCH.

Distilled feed water. C. F. HIRSHFELD. *Eng. Mag.* 49, 725 (1915).—H. reviews present chem. methods of feed water treatment and discusses various means for obtaining distd. feed water.

A. N. BENNETT.

Arsenic content of filter alum. E. BARTOW AND A. N. BENNETT. *J. Am. Water Works Assoc.* 2, 585-95 (1915).—A minimum of 0.8 and a maximum of 4.0 p. p. m. of As_2O_3 was found in the alum used by Illinois water purification plants. Samples obtained from 17 sources outside of Illinois showed an As_2O_3 content of between 0.5 and 1240 p. p. m. An expt. treating water with 6 grains per gal. of an alum containing 941 p. p. m. of As_2O_3 showed that 78% of the As was pptd. and could be recovered in the sludge. It is concluded that an alum of low As content can readily be obtained and that water works officials should specify a low content.

W. F. LANGLEIER.

Effect of algae on bicarbonates in shallow reservoirs. S. T. POWELL. *J. Am. Water Works Assoc.* 2, 703-8 (1915).—Certain forms of algae can entirely remove free CO_2 from water and can convert bicarbonates to normal carbonates by removal of the half-bound CO_2 . The dissolved O at the same time is greatly increased, thereby materially changing the chemical compn. of a water. In the case under observation in 2 reservoirs, in addition to complete removal of free CO_2 , there was a bicarbonate de-

crease of from 52 to 43 p. p. m. and then a further decrease of 11 p. p. m.; a dissolved O increase from 90% to 125% of satn. and an algae increase of 444.2%. CuSO_4 was used to destroy algae after which there was a great increase in the number of bacteria.

D. K. FRENCH.

Preventing boiler scale formation by means of aluminium. I. POUGET. Paris. *Lumiere elec.* 30, 284(1915); cf. *C. A.* 10, 362.—By actual test P. finds that after 15 days heating of 2 small boilers, the one with Al (Al powder was contained in a small bag suspended in the boiler) had a scale of but 7 g. whereas the one without the Al had scale of 17 g. Coarse Al grains were not as efficient. The best results were obtained with Al "bronze" made up with fine powder added to oil of turpentine and a little resin.

C. G. F.

Leading situations in the waterworks field. *Eng. Record* 73, 6-7(1916).—Litigation at Denver and San Francisco with water companies is detailed.

F. B.

The disposal of waste liquors from industrial plants. E. ROTH. *Völjschr. off. Gesundh.-Pflege* 47, 129-68; *Chem. Zentr.* 1915, II, 727.—The legal ordinances which are of importance to health officers as forming a basis for the control of waste liquors are discussed. The compn. and disposal of the following org. wastes are dealt with: Sugar, starch, brewery, dairy, slaughter house, tannery, wool scouring, cellulose, strawboard, paper, bleachery and dyes. Inorganic wastes are: NH_3 , mine, metal working, potash liquor, chemical manuf., electric and automobile works. The ordinance of April 7, 1913, is given verbatim.

W. F. LANGEЛИER.

Sewage disposal for manufacturing plants. H. WINKELMANN. *Z. angew. Chem.* 28, I, 331-2(1915).—Preliminary treatment of the waste in septic tanks and subsequent treatment in contact beds or trickling filters (preferably the latter) are recommended. Details of plant design and comments on the proper mode of operation are given.

W. F. LANGEЛИER.

Experts testify on means of eliminating odors in garbage reduction. ANON. *Eng. Record* 73, 20-1(1916).—Suit at Springfield, Mass. evokes opinions regarding best methods of treating foul gases from digester tanks.

FRANK BACHMANN.

The character and extent of atmospheric pollution in English and Scotch towns. J. B. C. KERSHAW. *Mel. Chem. Eng.* 13, 967(1915).—The atm. burden of soot and dust in tons per sq. mile area per yr. for various towns is as follows: Oldham 1064, Birmingham 764, Sheffield 642, Manchester 526, Malvern 64. The results were obtained by the analysis of rain water and are reported as tar, carbonaceous matter and ash. A device for measuring sunlight is described and it is shown that approx. 12% of sunlight is cut off in the lowest 100 feet of atm.

F. N. CRAWFORD.

Phenol coefficient of germicides. F. B. KILMER, A. W. CLARK AND P. HAMPTON. *J. Ind. Eng. Chem.* 8, 45-7(1916).—The writers discuss their experiences in trying to check the results of another lab. in detg. the coeff. of camphenol using the Hygienic Laboratory method. It is claimed that the method as outlined in *Bull.* 82 is not explicit enough. Investigation showed that the inability to obtain a satisfactory check was due to the fact that the 2 labs. used broth of different compn.

W. F. LANGEЛИER.

Use of alkaline hypochlorites as disinfectants. P. BRETEAU. *J. pharm. chim.* 12, 248-9(1915).—When an alk. hypochlorite soln. is dild. with distd. H_2O , there is dissociation of the salt and loss of a small amt. of Cl. (1) When 5 cc. of a soln. containing 0.047 g. active Cl are dild. with 400 cc. H_2O , there is loss of 3.8% of titer, due to dildn. This loss is increased, even doubled when dildn. is made with H_2O containing slight amts. of carbonates, bicarbonates or chlorides. (2) The remaining hypochlorite is dissociated by about 0.4 if dildn. is made with 200 cc. distd. H_2O , by 0.6 if dild. with 400 cc. Small amts. of NaHCO_3 or NaCl do not hinder the dissociation; but small

amts. of Na_2CO_3 reduce it by $\frac{1}{2}$. (3) When 1 drop of Javel water is added to 1 liter of H_2O , the hypochlorite may be considered almost completely dissociated. Acidification would not contribute further to bactericidal action. (4) The same is not the case for Labarraque soln., which contains excess of Na_2CO_3 , and whose diln. is made with only a few vols. of H_2O . The addition of an excess of boric acid with or without subsequent addition of NaHCO_3 seems bound to increase the disinfecting power of this alk. hypochlorite soln. S. WALDBOTT.

The sterilization value of "Katacid" and the precipitation of bacteria by ferric hydroxide. P. KÖTHNER. Univ. Marburg. *Arch. exp. Path. Pharm.* 79, 118-37 (1915).—Strauss's "Katacid" tablets, containing about 0.4 g. H_2O_2 , 0.53 g. citric acid and traces of catalase (absent in many preps.) are not suitable for sterilizing drinking water. Better results are obtained by using a soln. containing 2.5 g. citric acid, 0.379 g. FeCl_3 and 1.0 g. $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ per l. C. J. WEST.

Determination of carbon dioxide in sea water (MORGULIS) 11B. Sewage sludge for gas making (SNYDERS) 21.

Purifying water. H. NEEL. Brit., 19,722, Sept. 12, 1913. Excess of Cl is removed from H_2O which has been treated for purification, clarification, or sterilization with Cl or compds. of Cl such as NaOCl or $\text{Mg}(\text{OCl})_2$ by addition of FeSO_4 and filtration through base-exchanging bodies, such as permutite, containing Mn. Thiosulfate, sulfites, or bisulfites may be added before or after the FeSO_4 , and "ferric alumina" (containing sulfates of Fe and Al), $\text{Al}_2(\text{SO}_4)_3$ or other salt, alum, Mn salts, or other clarifying agents may be added at any stage prior to filtration.

Purifying and filtering water. C. J. RICHARDSON and F. KNIGHT. Brit., 20,170, Sept. 25, 1914. A filter comprises, within a single casing, a cloth filter and a container for ppt.-forming chemicals which is situated adjacent to but out of the direct path of the liquid entering at a suitable inlet. The liquid upon entering the filter dissolves the chemicals and deposits the ppt. upon the cloth, the ppt. thus forming the filtering medium. The chemical may have a sterilizing action and may consist of $\text{Al}_2(\text{SO}_4)_3$ and Na_2CO_3 together with bleaching powder, or a mixt. of alum and bleaching powder.

Purifying sewage. W. JONES and JONES & ARTHUR. Brit., 19,915, Oct. 11, 1913. In purifying sewage and other impure liquids, the sewage, etc., is aerated and forced from one compartment or tank to another by means of compressed air introduced by a pipe into the lower end of an uptake pipe which delivers into the upper funnel-shaped end of a down-take pipe terminating in a hollow chamber or foot vessel. The falling column of liquid in the down-take pipe draws in air through a suitable pipe. Air sepg. from the liquid in the foot vessel escapes through holes into the liquid in the 2nd tank, while the liquid containing the remainder of the absorbed air passes out through apertures in the bottom of the foot vessel.

Purifying sewage. W. JONES and JONES & ARTHUR. Brit., 19,916, Apr. 11, 1914. In a tank in which sewage, etc., is treated with diffused air, diffusers of porous material are arranged in the bottom of the tank at distances apart so that an up-and-down circulation and distribution of the liquid takes place, the bottom of the tank being curved or inclined downwards to the diffusers from points between the same to cause the deposited solids falling to the bottom of the tank between the diffusers to pass under the influence of the air currents from the diffusers. Cf. C. A. 9, 1814.

Aerating sewage. G. W. NAYLOR and J. F. NAYLOR. Brit., 20,259, Sept. 28, 1914. Sewage is aerated by air forced through porous tiles laid at the bottom of a sewage tank and supplied with air by horizontal pipes laid on or embedded in the base of the tank. Each tile or each row of tiles encloses an independent air space.

Sewage filtering system. R. W. AMOS. U. S., 1,165,741, Dec. 28.

Destructor furnaces. S. O. S., LTD. and E. W. JANSON. Brit., 19,561, Sept. 8, 1914. In app. for treating fecal or other sewage matter of the kind comprizing a mechanical retort having a series of superposed chambers with revolving arms or scrapers mounted on a vertical shaft and with hollow floors through which are passed furnace gases, heated feed-rollers are arranged in the feed-hopper for evapg. urine and destructively distg. the organic contents thereof.

Fertilizer from sewage. T. K. IRWIN. U. S., 1,166,373, Dec. 28. Basic or acid phosphate is added to a flowing stream of sewage and the ppt. formed is collected and mixed with yeast and starch waste or other fermentable matter which causes the solid material in the ppt. to rize to the surface, so that the liquid may be drawn off. Cf. C. A. 9, 3111.

Disinfectant. C. S. MINER. U. S., 1,167,360, Jan. 4. A dry powdered mixt. is made of CaO 98% and KMnO₄ 2%, which when moistened liberates O.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

The principles of crop production. EDWARD J. RUSSELL. *J. Chem. Soc.* 107, 1838-38(1915).—A lecture. W. H. FRY.

Salts, soil-colloids and soils. L. T. SHARP. Coll. Agr. Univ., Cal. *Proc. Nat. Acad. Sci.* 1, 563-8(1915).—A preliminary statement of the effect of certain substances upon soils before and after leaching. W. H. FRY.

The development of a dynamic theory of soil fertility. FRANK K. CAMERON. *J. Frank. Inst.* 181, 27-49(1916).—Early theories, the humus theory and the mineral theory are briefly discussed and the dynamic theory described at length. The role of the soil soln. in the nutrition of plants receives special consideration. W. H. FRY.

The adsorption of potassium by the soil. A. G. MCCALL, F. M. HILDEBRANDT AND E. S. JOHNSTON. *J. Phys. Chem.* 20, 51-63(1916).—Durham sandy loam soil was used as the adsorbing material and KCl as the material to be adsorbed. The app. used consisted of a porcelain-lined filter chamber into which was fitted a short filter tube, made by cutting off the upper end of a Pasteur-Chamberland filter tube and forcing it down over the projection on the rubber gasket at the bottom of the chamber. A brass jacket, which serves as a container for the soil, surrounded the filter tube. Twenty g. of air-dry soil were used as a charge, being placed in the brass jacket; the salt soln. was poured into the porcelain-lined chamber. The filter tube serves to give a clear filtrate. Grinding the soil very fine by means of a ball mill increased the solubility of the soil K 10-fold. In the expt. in which the KCl soln. was run through the 20 g. of soil the concn. of the soln. was first decreased from 62 parts per million of K to 40 p. p. m. and later to 36 p. p. m. After this, with a further supply of soln. the strength of the soln. rose to within 3 p. p. m. of that of the original soln. It is shown that the amt. of K retained by the soil after the passage of 250 cc. of KCl soln. is 233 p. p. m. By passing 300 cc. of water through the soil the adsorbed K was reduced to 99 p. p. m. The authors also give results on the adsorption of K from KCl soln, by finely pulverized soil and in addition the amt. of K adsorbed from such soil by water alone. B. E. B.

The determination of nitrates in soils. P. S. BURGESS. Honolulu, H. I. *Science* 43, 67-8(1916).—Polemical. B. favors the Al reduction method. W. H. FRY.

Soil gases. J. W. LEATHER. *Mem. Dept. Agr. India (Chem. Ser.)* 4, 85-134 (1915).—The object of this investigation was to det. the compn. of the gases in the soil

under various conditions, and the rate of diffusion of gases out of and into the soil. In unmanured fallow soil the % of O varied from 16 to 18% in the hot dry season and was higher than in the cool wet season, when it varied from 8 to 12%. The % of CO₂ varied within wide limits, and was as high at a depth of 5 and 6 ft. as in the surface soil. In a manured soil the % of O was slightly less than in the unmanured, and there was an increase in the amt. of CO₂. The amt. in the surface and subsoil was practically the same. With green manured soil the results were indecisive except that the % of N was greatly increased. An analysis of the gas from a swamp rice soil showed it to be composed of 84.2% N, 4.3% CO₂, 8.8% H, 1.4% CH₄ and less than 1% of O and A. The vol. and compn. of the gas surrounding the roots of growing *Crotalaria juncea*, *Indigofera arrecta* and *Zea mays* are given. The % of N was about the same in the gas surrounding each plant. The O was higher from the *Zea mays* and the CO₂ was higher from the *Indigofera arrecta*. The other constituents varied but slightly. In green manured soil the quantity of O diffused is much in excess of that required for CO₂. In the neighborhood of growing crops, N, CO₂ and in some cases H were found to be passing out of the soil while O diffused into it.

J. J. SKINNER.

Effect of temperature on some of the most important physical processes in soils. GEORGE J. BOUYOVOS. Michigan Agr. Expt. Sta., *Tech. Bull.* No. 22, 63 pp. (1915).—Data are presented on the influence of temp. on capillary movement and retention of moisture, gravitational flow of water, thermo-osmosis, gas flow, aeration of soils, etc.

B. E. B.

Cyanamide, dicyanodiamide, and calcium cyanamide. J. C. DE RUIJTER DE WILDT AND A. D. BERKHOUT. *Versl. Landbouwk. Onders. Rykslandbouwproefstat* 1913, No. 13; *J. Soc. Chem. Ind.* 34, 972.—Cyanamide (0.5%), when kept for 3 years in 0.002 N solns. of NaCl, NH₄Cl and KCl, was only slightly decomposed; in presence of CaCl₂ (0.002 N) and CaCO₃, decompn. was more marked. Mineral acid solns. (0.02 N) contg. 0.5 and 1.0% of cyanamide, which were kept for 2 months, were found to contain urea. The results of pot expts. in which buckwheat grown in humus sand received cyanamide and Fe oxide showed that the Fe was without effect. Decompn. of CaCN₂ when stored is shown to be due to atm. moisture rather than to CO₂; production of dicyanodiamide is to be expected more than loss as NH₃. CaCN₂ may be mixed with K₂SO₄, magnesia and kainite. The results of fertilizing expts. with fresh and with stored CaCN₂ showed that the value of the stored fertilizer was considerably less than that of the fresh.

E. J. C.

Composition of wood and plant ash. R. A. BERRY. *J. Board Agr.* 22, 766-8 (1915); *J. Soc. Chem. Ind.* 34, 1263.—The quantities of potash and of H₃PO₄ present in various wood ashes, etc., are shown in the following table:

Ash.	Potash (K ₂ O).		Phosphoric acid (P ₂ O ₅). Total %.
	Total %.	Sol. in water. %.	
Bracken.....	20.45	10.61	3.37
Spruce.....	11.94	8.23	7.01
Hardwood, largely oak trimmings	3.53	2.75	
Mixed forest produce.....	3.13	1.50	1.54
Soft wood, forest fire.....	11.79	6.53	5.23
Hardwood, engine fire.....	10.44	6.77	5.02
Flue dust from blast furnaces...	3.75-3.93	2.13-2.64	

The phosphates are present chiefly in the form of Ca and Mg phosphates. While it is difficult to value the ashes for fertilizing purposes on the basis of the total potash, it is evident that four of the above ashes could be used in place of a low-grade potash fertilizer, such as kainite. The phosphates have much the same value as those in

steamed bone flour. From the "lop and top," undergrowth, weed growth, and litter in any av. type of woodland, about 0.5 ton of ash is obtained per acre; 10 acres of fully stocked bracken land produce 1 ton of ash. Cf. Russell, *C. A.* 9, 684. E. J. C.

Cause of the occasionally observed red coloration of the sulfuric acid solution of Thomas meal. HUGO DIRZ. *J. prakt. Chem.* 91, 507-20(1915).—The color is due to a mangani-phosphoric acid compd. It does not appear if the meal contains an excess of reducing substance. Meals which gave the usual green color on digestion with H_2SO_4 could be made to give the red color by sufficient preliminary roasting of the meal with the Bunsen burner or the blast. L. J. GILLESPIE.

Lead nitrate as a catalytic fertilizer for sugar beets. J. K. GREISENEGGER. *Oesterr.-ung. Z. Zuckerind.* 44, 91-6(1915).—Expts. in which $Pb(NO_3)_2$ was used, together with superphosphate and potash salt as a fertilizer for sugar beets, show that this compd. either does not affect the quality of the beet at all, or that its effect is so uncertain that it must be used with great care. E. A. TSCHUDY.

Blasting artificial fertilizer heaps. WILHELM SZIGHTI AND WILHELM FÄRBER. *Brassó. Chem. Ztg.* 40, 11(1916).—For drilling holes in heaps of hardened superphosphate sharpened Fe or steel tubes, provided with a head for hammering, have proved better than a spiral borer. A cut of a simple press is shown for making superphosphate plugs for tamping. J. H. MOORE.

Effect of elemental sulfur and of calcium sulfate on certain of the higher and lower forms of plant life. WALTER FITZ. *Agr. Expt. Sta., Univ. Wis. J. Agr. Research* 5, 771-80(1916).— $CaSO_4$, when added to a soil, apparently has no marked effect on the total number of bacteria that grow on agar plates; nor does it produce any marked increase in ammonification or nitrification. Large amts. of elemental S cause a decrease in the total number of bacteria that grow on agar plates, but produce an increase in ammonification at concns. of 0.05%. This increase is accompanied by a parallel decrease in nitrate formation. The decrease is very probably due to the acidity or toxicity produced by the oxidation of S. $CaSO_4$ stimulates the growth of pure cultures of red-clover bacteria in nutrient solns. and in soil exts. The increase is as great with 0.01% as with 0.1%. The root development of red-clover is increased by $CaSO_4$, the above per cents. apparently being equally efficient. In small amts. $CaSO_4$ increases the yield of red clover and also the number of nodules. Concns. as high as 0.5 to 1% however, produce no increase in growth. The application of elemental S to Miami silt loam soil increased but slightly the yield of clover and apparently did not affect root development or nodule formation. In producing this slightly increased growth 0.01% was as efficient as were higher concns. W. H. FRY.

The influence of nitrates on the development of root tubercles. A. J. EWART. *J. Dept. Agr. Victoria* 13, 759-60(1915).—The object of this investigation was to det. whether or not the addition of nitrate to the soil decreases the formation of root tubercles in legumes. The total yield of beans (*Vicia faba*) fertilized with KNO_3 was slightly greater than in the case of the control and the yield with $NaNO_3$ was the same as that of the control. The nitrates used did not diminish appreciably the formation of root tubercles, yet their use as fertilizers proved unprofitable, the plants being able to gain all the N they required through their root tubercles. J. J. SKINNER.

How contact insecticides kill. III. GEORGE D. SHAFER. *Michigan Agr. Expt. Sta., Tech. Bull.* No. 21, 67 pp.(1915); cf. *C. A.* 6, 525.—S. has studied the properties of CS_2 , gasoline, and a few other liquids, and certain dry powdered contact insecticides, e. g., borax, NaF, white hellebore, etc., which give them insecticidal action after their absorption into the insect tissues. The effect of temp. also was studied. Suggestions for possible practice are given. Reductases, catalases and oxidases were

found in aq. exts. and in the insol. pulp of the tissues of insects, which were injuriously affected by heat, and by gasoline, CS_2 , borax, etc., if in great enough concn. It was shown that an absorption of gasoline ensued when the living insect was subjected to the influence of air laden with gasoline vapor which rendered the membranes (fat-like) less permeable to oxygen. Absorption of certain solid insecticides was shown. Generally these act as stomachic poisons. B. E. B.

Fertilizer. T. L. WILLSON and M. M. HAFF. U. S., 1,166,104, Dec. 28. A dry fertilizer containing CaNH_4PO_4 , a small amount of NH_4 phosphate and free from acid is mixed with NH_4Cl , $\text{Ca}(\text{NO}_3)_2$, NaNO_3 , KCl or other fertilizing salts.

Salts; nitrates; fertilizers. NORSK HYDRO-ELEKTRISK KVAELSTOFAKTIESELSKAB. Brit., 19,791, Sept. 15, 1914. Salts such as $\text{Ca}(\text{NO}_3)_2$ and NH_4NO_3 , which may be used as fertilizers, are prevented from hardening into lumps by mixing with diatomite or kieselguhr, a small quantity being sufficient. The salt may be heated directly or by blowing hot gases therethrough before mixing with the kieselguhr.

Insecticide. A. S. RAMAGE. U. S., 1,166,387, Dec. 28. A H_2O -repellent insecticide for spraying on plants is formed by coating particles of Pb arsenate with Pb stearate or other Pb soap, e. g., pptg. the insol. soap in an aq. suspension of Pb arsenate, Cu soap may be similarly pptd. on Paris green.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Physico-chemical study of wine. Electrolytic dissociation constant of wine. CLELIA DI MAIO. Milano. *Ann. chim. applicata* 4, 245-68(1915).—The process of dissociation follows, with sufficient approximation in genuine wines, the law of diln., $K = \alpha^2/(1 - \alpha)v$, in which K = dissociation const., α , the degree of dissociation of the binary electrolyte, v , the vol. in which the gram-mol. is dissolved. K has different values for different wines, but the variations are comprized within narrow limits, so that the appreciable convergence permits of the application of the method in detg. adulteration with strong mineral acids. K , for 9 wines examd., had an av. value of 0.0184 ± 0.0016 , with probable variations of 9.1%. When strong mineral acids are added to wines, they alter considerably the value of K , and if in quantities above 0.5%, change very much the degree of constancy in relation to the prevalence of strong electrolytes that do not follow the law of diln.. This lack of uniformity in the value of K also exists in those wines poor in natural acidity, to which metabisulfite has been added. While the study of the variations of K is of great importance in recognizing genuine wines, the difficulty and laboriousness of the methods of research limit its practical application at the present time. S. LEVY.

Proceedings of the chemical research and pure yeast breeding laboratories and of the institute cellars of the K. K. Höheren Lehranstalten für Wein- und Obstbau in Klosterneuburg. W. SEIFERT. *Separate* 56 pp.; *Chem. Zentr.* 1915, II, 161.—On freezing the must an abundance of $\text{HKC}_4\text{H}_4\text{O}_6$ sepd. The unfrozen portion tasted like the original wine, and the ice water possessed a wine-like character. By sub-cooling, new wines changed their characters in a manner not understood. During the formation of volatile S compounds, a small and regular increase in the sugar content was noted in the fermenting mass, but no marked increase of AcOH was observed. Expts. on the action of different breeds of yeast upon $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ during their growth and fermentation in beer worts seemed to show that the disappearance of large amts. of the free acid was due

to bacteriologic rather than to chem. activity, and was dependent upon the lively condition of the yeast. Yeast cultivated in unsulfured must was more resistant toward SO_2 , than if cultivated in the presence of SO_2 . CHCl_3 up to 4 cc. and $\text{C}_2\text{H}_5\text{CNS}$ up to 13 drops per liter of must appear to be the limits to which these agents can be added without lessening the activity of *penicillium*. SO_2 bleaches the color of red wine but the color slowly returns, reaching its original intensity in 14 days; this shows that the color is not decomposed. The peronospora activator "Diasogen" contains soft soap 35 and HCHO 6%; on trial it gave a negative result. The "copper-sulfur paste" of Heider in Warnsdorf has the following compn.: At 105° the liquid constituents amount to 68.49, CuS 22.10, CuSO_4 3.86, Fe_2O_3 + Al_2O_3 0.10, H_2SO_4 2.16, Cl 0.38, water of crystn. 0.44%.
L. W. RIGGS.

Acid ratio of malt. A new basis for malt valuation. C. A. NOWAK. Communications U. S. Master Brewers' Assoc.; *Brewers' J.* 51, 509-12(1915); cf. C. A. 10, 367.—N. considers the malt acidity of greatest moment in the valuation of malt for brewing purposes. Basing his conclusions on a careful study of the analytical data covering several thousand malt analyses, he finds that: Malts giving highest acidity in cold water ext. will invariably yield a lab. wort which filters more rapidly and is far more brilliant than a wort prepd. from a malt which has a comparatively low acidity. He also finds that: (1) Medium-berried barleys are, as a rule, preferable for malting purposes. (2) Brilliancy of filtration and yield of ext. are partially dependent upon the natural acidity of the malt. (3) Six-rowed, two-rowed, and Western malts behave differently and require different standards of valuation. (4) Growth and kilning-off temp. exert a far-reaching influence upon the acid ratio. N. sees no reason why two-rowed barleys could not be so malted as to be high in acid ratio and yield a malt well suited for the prepn. of stable bottle beer.
C. A. NOWAK.

Determination of moisture and bitter principles in hops. D. WIEGMANN. *Allgem. Brau.-Hopfen-Ztg.* 55, 1711-2(1915).—A reply to Ö. Winge's response (C. A. 10, 248) on D. Wiegmann's criticism (C. A. 10, 248).
L. W. HAAS.

Barleys of crop 1915. R. HEUSS. *Z. ges. Brau.* 38, 393-4(1915).—Analyses of Bavarian barleys from 29 different localities are given with regard to moisture, N, protein, starch, yield of ext., hl-wt., 1000 berry wt., assortment as to size, and germination energy and capacity. The av. protein content of 12.53% exceeds that of the previous crop by 1.2%, while with regard to the other data, there is a general resemblance between this and last year's barleys.
L. W. HAAS.

The resins in hops from various geographic localities. G. A. RUSSELL. *J. Ind. Eng. Chem.* 7, 1033-5(1915).—R. intended to investigate the variations in the compn. of hops due to locality and season, and to establish the influence of the size of the sample on the final result of hop analyses. The soft resins were extd. by petr. ether (b. p. $35-60^\circ$) and the hard resins subsequently by Et_2O . R. draws the following conclusions: One 10 g. sample picked either at random or from selected cones does not give a correct index to the amt. of soft resins in a quantity of hops. The av. from a number of detns. of 10 g. samples picked at random gives a true value of the amt. of soft resins in a quantity of hops, as likewise does one large representative sample of approx. 1.5 kg. wt. The yield of soft resins varies from season to season in the same and in different localities. The percentage of ash in hops varies in samples from different localities but remains approx. the same in samples from the same locality from year to year.
L. W. HAAS.

Determination of moisture in worts, sugar solutions, barley, hops, malt sprouts and yeast by means of the carbide method. W. WINDISCH AND M. GLAUBITZ. *Wochschr. Brau.* 32, 389-91, 397-8(1915).—The quantity of C_2H_2 evolved was detd. from the loss in wt. of the small app. used for the detns. For the detn. of moisture in barley,

malt, hops, dregs, grounds (lees), etc., the carbide method gives acceptable results, which are regularly higher than those by direct drying. The difficulties of accurate moisture or ext. detns. in worts are not yet overcome by the carbide method. With worts or similar solns., the regulation of the flow of gas can cause difficulties leading to erroneous results. A principal weakness of the carbide method is the necessary employment of very small quantities of soln. (0.2–0.4 g.) to work with. The investigations are being continued, using an entirely different arrangement, which allows working with a far greater quantity of soln. and promises most accurate results.

L. W. HAAS.

Fermenting vessels. P. ROHLAND. *Z. ges. Brau.* 38, 203–5 (1915).—Aluminium vessels, which are enveloped by concrete or a brick wall, usually show after a short time bad corrosions (white efflorescence of Al_2O_3). These may be caused by the alkalinity of the mortar and concrete on getting damp or by electrolytic oxidation due to the impurities of the Al employed in conjunction with the damp mortar or concrete serving as electrolyte. R. recommends the coating of Al vessels first by a protective and insulating layer (asphaltic material, etc.) and then enveloping by concrete or brick walls.

L. W. HAAS.

Change in the nutritive value of potatoes by the distilling process. W. VÖLTZ. *Z. Spiritusind.* 38, 145–6, 153–4 (1915).—Expts. on ruminantia and omnivora revealed that the transformations in the utilizable nutritive substances in potatoes involve a gain of 7.2% for the former against a loss of 6.3% for the latter. L. W. HAAS.

Bákhar, the Indian rice-beer ferment (HUTCHINSON) 11C. Estimation of methyl alcohol in presence of ethyl alcohol (REIF) 7. Glycerol determinations in wine (KALUSKY) 12.

Extracting hops. T. R. SHERCLIFF. *Brit.*, 19,380, Sept. 3, 1914. An app. is specified.

Oxygenated water for malting purposes. O. SCHULZE. *Ger.*, 283,532, July 4, 1913.

Light and dark caramel malt. A. BEHR. *Ger.*, 282,646, Aug. 1, 1912. The green malt is saccharified by treatment with hot air, supersatd. with moisture and having a circular motion; then it is dried, and roasted by superheated air. The germination of the green malt follows according to a special process.

Removing bitter constituents of malt extracts having a burnt taste and odor. E. CANTOR. *Ger.*, 283,471, Mar. 7, 1913. The removal of these substances from colored malt ext., wort, or beer, is effected easily by the passage of steam through these worts.

Obtaining acetone and alcohol by fermenting sugar and materials containing sugar. BAYER & Co. *Ger.*, 283,107, July 19, 1913. Sugar cane 90 is mixed with malt-husks 60, chalk 45, and H_2O 3000, and sterilized for 20 min. at 2 atms. After inoculation with *B. macerans*, an active fermentation takes place at 40°, and after 5 days the cane sugar has disappeared completely. About 30 parts of alc. and acetone, however, are found in the mash. Without the husks, a yield of 10 parts is obtained during 7 days of fermentation. Cf. C. A. 9, 3326.

Non-alcoholic wine. M. DÖNITZ. *Ger.*, 283,641, Dec. 7, 1913. Wine, freed from alc. by the usual process, is mixed with H_2O , without the addition of sugar, and then subjected to fermentation with yeast with the formation of alc. Cf. C. A. 9, 2791.

Rendering used sparkling-wine bottles suitable for re-use for the same purpose. H. EBBERT. *Ger.*, 284,515, Mar. 11, 1914. The old bottles are heated to a high temp.,

preferably until they begin to soften, then cooled slowly in the known manner, and finally filled with the crude wine and carried through the sparkling-wine manuf. in the usual manner.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Procedure for the mechanical purification of used alcohol by means of a drop of paraffin. A. POHL. *Deut. med. Wochschr.* 41, 1373(1915).—Alc. contaminated by particles of dust, etc., is put in a dish and some paraffinum liquidum is dropped in. Moving the dish about the drop of paraffinum rolls along the bottom and takes up all particles. The alc. can also be shaken in a bottle with a little larger amount of paraffin leaving a heavy residue. S. AMBERG.

Method for the determination of tobacco resins and its application to various tobaccos. J. VON DEGRAZIA. *Fachliche Mitt. der österreichischen Tabakregie* 1914, 1-4; *J. Soc. Chem. Ind.* 34, 978; cf. *C. A.* 8, 3096.—Two portions of 60 g. each of the dry powdered tobacco are extd. in a Soxhlet app. with ether, about 100 g. of ether being used for each portion. One of the ethereal solns. is then washed with water contg. a small quantity of acid to remove nicotine, the ether evapd., the residue dissolved in 90% alc., and the soln. strongly cooled. After the sepd. wax has been removed, the alc. soln. is boiled with the addition of 150 cc. of 2% KOH soln., and the mixt. is extd. with ether; the ethereal soln. contains the tobacco resin, together with small quantities of ethereal oils. The soln. usually has a reddish brown color, but in the case of Cserbel tobacco it has a green color. After the ether has been evapd., the residue of tobacco resin is weighed. The alk. soln. contains the resin acids and the resin alc.; the latter is in suspension, and is sepd. and weighed, while the resin acids are sepd. by extn. with ether in the usual way, the ethereal soln. evapd., the residue weighed, the acids dissolved in alc., and the tobaccic acid pptd. by the addition of alc. Pb(OAc)₂ soln. The Pb salt is sepd. by filtration, and the filtrate mixed with ten times its vol. of water acidified with HNO₃; the β -tobaccic acid which seps. in flocks is collected, dissolved in ether, the soln. evapd., and the residue weighed. The γ -tobaccic acid is found by difference. The other portion of the ethereal soln. is evapd., and the residue extd. with alc. to dissolve the α -tobaccic acid; the alc. soln., which contains tannin and nicotine in addition to the acid, is evapd., the residue heated with very dil. KOH soln., cooled, filtered, the filtrate neutralized, and the sepd. α -acid collected. The following table shows the compn. of the resins from various tobaccos expressed as percentages of the latter; the figures indicate that it is possible to differentiate between different kinds of tobacco:

Kind of tobacco.	Total resin.	Wax.	Resene.	Acids.			Resin alcohol.
				α .	β .	γ .	
Havana.....	4.65	0.59	2.64	1.44	0.18	0.38	0.01
Brazilian.....	3.36	0.55	1.97	0.93	0.12	0.32	0.02

E. J. C.

Wood alcohol as denaturant. ANON. *Oil, Paint and Drug Rep.* 88, No. 26, 18 (1915).—Treasury decision, T. D. 3368, has been revized so that the specification

for the acetone content of approved wood alc. calls for not more than 20 or less than 10 g. of acetone per 100 cc. A method of detg. acetone by absorption of I is given.

E. W. BOUGHTON.

Comparative investigations on the evaluation of semen sinapis, spiritus sinapis, oleum sinapis and charta sinapisata. FR. WEHRMANN, K. WEGENER, FR. H. BRAUN-WARTH AND K. MEYER. *Arch. Pharm.* 253, 306-27(1915).—A résumé of the work by H. Frerichs. The investigation of W. and W. embodies a large number of expts. which relate, however, to the best known methods. M. likewise considers only the more common procedures and makes but few expts. B. treats the subject more from the literary than the practical side and considers some 25 fundamental methods for detg. ol. sinapis, together with variations of such methods. The work presents a very careful compilation of the available literature.

W. O. E.

Chrysanthemum cinerariaefolium Trev. P. SIEDLER. *Ber. pharm. Ges.* 25, 287-302(1915).—In addition to cultural and morphological data, the paper deals with the microscopical exam., the importance of pollen grains in identification, and the investigation of volatile principles. Steam distn. of the flowers yielded 0.067% of a peculiar aromatic, salve-like mass containing among other things the elements of palmitic and other fatty acids, unidentified phenols, ketone or aldehyde-like substances.

W. O. E.

Norwegian turpentine oil. H. W. FOSSE. *Ber. pharm. Ges.* 25, 303-13(1915).—The crude oil resulting from the distn. of pine and fir in closed retorts contained in addition to terpenes and sesquiterpenes oxygenated substances (resins) as well as S compds. belonging to the mercaptans. The terpenes consist largely of *d*-pinene and small quantities of sylvestrene. Cadinene could not be detected. Oil purified with CaOCl_2 proved to be free from S compds. and no longer possessed the disagreeable odor of the crude oil. A purified sample was found to be *d*-rotatory, thus indicating a possible change of *l*-pinene to *d*-pinene during the process of purification. Purified oil consisted of almost 80% pinene, with small quantities of sylvestrene and sesquiterpene. Pine oil was present in neither the crude nor purified product.

W. O. E.

The hypodermic injection of ergot and ergotinine. M. G. PEGURIER. *Reperl. Pharm.* 27, 265-9(1915).—The article calls attention to the confusion often observed in prescribing and using certain prepn. of ergot mentioned in the Codex. In order to obviate the uncertainty frequently obtaining in the administration of such products, suggestions are offered relative to the prepn. and sterilization of the solns. in question.

W. O. E.

Changes in iodized benzine. RAPP. *Pharm. Ztg.* 60, 609-10(1915).—The principal changes, due to age and the action of light, result in the formation of HI and an I deriv. of a hydrocarbon. Iodized petroleum ether was found to be more stable than iodized commercial benzine. The addition of paraffin liq. to iodized benzine is to be discouraged.

W. O. E.

Determination of chloroform in cough sirups. EARLE B. PUTT. *Am. Food J.* 10, 467-8(1915).—By analysis of more than 100 sirups, P. found that they contained CHCl_3 in amts. ranging from 5 minims to a fraction of one minim, an av. of 2 to 3 minims, per fluid ounce. Small amts. of CHCl_3 can be readily detd. by utilizing the well-known reaction with KOH and detg. the resulting KCl. For most sirups this method cannot be applied directly because of the presence of interfering substances. P. proposes a modification which makes the method applicable to all cough sirups and to other medicinal prepn. containing CHCl_3 such as pastilles and lozenges: For sirups, to a 10 cc. sample in a 250 cc. Kjeldahl flask add about 1 g. CaCO_3 (to neutralize free acid) and 80 cc. 95% alc. Distil through a vertical condenser, having a delivery

tube extending well down into a 150 cc. pressure flask standing in cold water, until about 70 cc. of distillate is collected. To the distillate add exactly 10 cc. standard alkali (100 g. KOH in 100 cc. H_2O), close the flask with a sound cork securely wired, mix thoroughly and heat on a gently boiling water bath for 1 hr., cool, transfer to a 400 cc. beaker and det. KCl with $AgNO_3$, either gravimetrically or volumetrically. For lozenges, etc., to about 2 g. of sample in 10 cc. of water the alc. is added and the chloroform distilled off as for the sirups, further procedure being identical. The method, checked with a known alc. soln. of $CHCl_3$, was found to be reasonably accurate.

G. A. MENGE.

Nature of pharmaceutical naphthene oil (liquid petrolatum). B. T. BROOKS. Mellon Inst., Pittsburgh. *J. Am. Med. Assoc.* 66, 24-6(1916).—The claim that Russian oils alone consist of naphthene hydrocarbons is not warranted as America has great quantities of petroleum of the same general characters as the Baku oil. Emphasis is laid on the necessity of a uniform nomenclature to be adopted to designate the viscous, water white, tasteless mineral oils which are now known by a score of trade names. Most of the so-called paraffin oils contain no paraffin being made up of the naphthene and polynaphthene classes; hence B. suggests that they be called "white naphthene oils." The most important tests for these preps. are taste, keeping quality and viscosity.

L. W. RIGGS.

Formic acid as a reagent in essential oil analysis. WM. H. SIMMONS. *Analyst* 40, 491-4(1915).—The use of HCO_2H as a reagent in the quant. analysis of essential oils is based on the fact that geraniol is very largely converted into terpenes by treatment with HCO_2H , while citronellol is esterified to citronellyl formate. The method is carried out by heating a mixt. of 1 vol. of oil with 2 vols. of 100% HCO_2H under a reflux condenser for 1 hr. on a boiling water bath, washing the esterified oil with brine until free from sol. acid, rendering it neutral to phenolphthalein, and then saponifying it with 0.5 *N* alc. KOH, and titrating back the excess of KOH with standard acid.

% citronellol =

$$\frac{\text{Number of cc. 0.5 } N \text{ KOH absorbed} \times 0.078 \times 100}{\text{Wt. of esterified oil taken} - (\text{number of cc. 0.5 } N \text{ KOH absorbed} \times 0.014)}$$

Wt. of esterified oil taken — (number of cc. 0.5 *N* KOH absorbed $\times$ 0.014)

S. has applied the method to a number of oils, including oils of geranium, peppermint, sandalwood, etc. In a previous paper he has shown that the decompn. of geraniol and the esterification of citronellol are incomplete (*Yearbook of Pharm.* 1913, 565-8; cf. also *C. A.* 7, 3816). He concludes from the present work, however, that terpineol is almost completely decompd. by formylation, geraniol and linalol are both converted into an appreciable quantity of ester, while santalol is only partially decompd., and citronellol, menthol and the borneol in rosemary oil may be approx. estd. by the process. The use of HCO_2H as a reagent is undoubtedly of value in the examn. of geranium oils, and, if the right conditions as to strength and proportion of acid and duration of heating can be detd., enables an accurate detn. of the proportion of menthol in peppermint oils.

P. B. DUNBAR.

Estimation of methyl alcohol in presence of ethyl alcohol (REIF) 7.

Medicinal composition. H. HÖRRLIN. U. S., 1,166,208, Dec. 28. β -Imidazolylethylamine hydrochloride is combined with 4 times its wt. of *p*-hydroxyphenylethylamine hydrochloride to obtain a medicine in which desirable physiological action of each constituent predominates without harmful after-effects such as follow the use of the constituents separately.

Aperient extracts. R. TAMBACH. U. S., 1,167,230, Jan. 4. An alc. ext. is prepd from rhubarb, cascara or senna and ether is added to the ext. as long as a ppt. is formed.

The liquid is then concd. by evapn. and reduced to the desired standard strength by addition of sugar of milk.

Lipoid compounds containing phosphorus from high-molecular fatty acid derivatives. F. HOFFMANN-LA ROCHE & Co. Ger., 284,736, July 31, 1914. Addition to 281,801 (C. A. 9, 2292). In order to obtain a purer product with a better yield than possible by the parent process, PCl_3 instead of phosphorous acid is allowed to act on the high-mol. keto fatty acids and their derivs.

Lipoid compounds containing phosphorus. F. HOFFMANN-LA ROCHE & Co. Ger., 285,991, Apr. 26, 1914. Addition to 280,411 (C. A. 9, 1708). The products are obtained from higher-mol. fatty acid derivs. The hydroxyphosphinic acids obtained according to the parent process are esterified according to the usual methods.

Separating the pharmacologically active constituents of *Cannabis indica*. F. HOFFMANN-LA ROCHE & Co. Ger., 285,829, Dec. 5, 1913. The exts. obtained from *Cannabis indica* with org. solvents, which are not miscible with H_2O , are treated with dil. alkali with exclusion of air, and from the resulting solns. the alkali-sol. and the alkali-insol. constituents are sepd. The resulting products are distinguished from each other in their poisonous and narcotic properties.

A tasteless cholic acid compound. Ger., 285,828, Mar. 19, 1914. BAYER & Co. Cholic acid is treated with acetyl formate or with a mixt. of AcOAc and HCOOH . In addition to the properties of cholic acid, the product possesses disinfecting properties.

Cobalt cholate. KNOLL & Co. Ger., 284,762, Oct. 21, 1913. Co cholate is obtained by the reaction between Co salts and alkali cholates.

Diarylurea chlorides. BADISCHE. Ger., 285,134, Aug. 5, 1913. COCl_2 is allowed to act upon diarylamines or their hydrochlorides, with heating and in the absence of substances which prevent the formation of diarylamine hydrochlorides, until the reaction mass contains no unconverted diarylamines or their hydrochlorides, or contains them only in inconsiderable amts.

Urea nitrate. ÖSTERREICHISCHER VEREIN FÜR CHEM. UND METALLURGISCHE PRODUKTION. Ger., 285,259, Mar. 19, 1913. The product is obtained by treating the aq. soln. of cyanamide with HNO_3 . The acid is added with continued cooling of the reaction mixt. in which the temp. must not be allowed to exceed $+20^\circ$. This is accomplished by evapg. the cyanamide soln. carefully, practically to the consistence of a sirup, taking care that it does not become alk. by adding small amts. of free acid (HNO_3 , H_2SO_4 , etc.). The sirupy cold lye is carefully cooled, and HNO_3 of 40°Bé . is added with stirring, so slowly that the cooling prevents a rise in temp. until the gas evolution begins. Even a temp. of $+20^\circ$ is to be avoided. The lye thickens finally to a stiff slurry. The ppt. is then drained and must be freed from adhering HNO_3 by covering it with concd. aq. soln. of urea.

Ureas of the naphthalene series. BAYER & Co. Ger., 284,938, Oct. 17, 1913. Addition to 278,122 (C. A. 9, 1096). According to the process of 278,122, ureas of the naphthalene series are obtained by treating aminobenzoylated 1,8-aminonaphthol-sulfonic acids with COCl_2 . The same products are obtained if in these aminonaphthol-sulfonic acids the aminobenzoyl residues and their derivs. are wholly or partially substituted by aminobenzenesulfonyl residues, their homologs or substitution products.

Compounds of urethans and diurethans with methyl bromides. GEHR & Co., AKT-GES. Ger., 284,734, May 14, 1913. The urethans are heated with CaBr_2 or SrBr_2 in a suitable solvent in the mol. proportion of 1 to 4. The process is completed in several hrs.

Hydroxyisopropyl derivatives of hydrocarbons and their derivatives. BAYER & Co. Ger., 284,764, Nov. 29, 1913. Addition to 280,226 (C. A. 9, 1371). In the

parent process for the introduction of the hydroxyisopropyl group into organic compds. the compds. (ketones, aldehydes, etc.) are allowed to act upon the soln. of Na acetone in ether, ligroin, etc., at a low temp. Instead of Na acetone, other ether-sol. alkali compds. of acetone can be employed.

Derivatives of 2,3-hydroxynaphthoic acid amide. BAYER & Co. Ger., 284,997, Nov. 29, 1913. These derivs. are obtained by the action of the halides of 2,3-hydroxynaphthoic acid, or of the free acids in the presence of dehydrating agents, on aminonaphthols.

Hydrazine monocarboxylic acid esters. E. MERCK. Ger., 285,800, Feb. 12, 1914.

Sulfomethylbenzophenone-*o*-carboxylic acids. FARBW. v. M. L. & B. Ger., 285,700, Oct. 21, 1913. These acids and their substitution products are obtained by oxidizing *unsym*-dimethylbenzophenonesulfonic acids obtained from the chlorides of benzoic acid and their substitution products with *m*-xylene followed by sulfonation.

Ethyl acetate. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. Ger., 285,990, Jan. 31, 1914. Addition to 277,111 (C. A. 9, 1829). In accordance with the parent process the production of EtOAc from AcH is effected with the employment of an alcoholate catalyzer. A more practicable procedure consists in applying this alcoholate catalyzer in dissolved form, preferably in AcOEt soln. The procedure is preferably such that the solvent acts simultaneously with the aldehyde upon the catalyzer. Cf. C. A. 9, 1226.

Acetic anhydride. BOSNISCHE ELEKTRIZITÄTS-AKT.-GES. Ger., 284,996, Jan. 20, 1914. For the manuf. of Ac₂O from the HOAc esters of the aliphatic aldehydes with not more than 4 C atoms, these esters are heated, alone, above the b. p. They may also be warmed with catalyzers or superheated highly in their presence.

Formates. G. BREDIG and S. R. CARTER. Ger., 283,895, Dec. 23, 1913. Salts of HCO₂H are obtained by the catalytic reduction of carbonates and bicarbonates.

Crystalline polymerization products of formaldehyde. F. POLLAK. Ger., 284,756, Dec. 14, 1912.

3-Methyl-butinol and its homologs. BAYER & Co. Ger., 285,770, Nov. 22, 1913. These products are obtained by allowing acetone or its homologs to act upon the alkali compds. of C₂H₂ and its homologs.

Esters of orthosilicic acid. L. KNORR and H. WEYLAND. Ger., 285,285, Mar. 22, 1914. Esters of H₄SiO₄ with polyvalent alcs. are obtained by heating the simple silicic acid esters, such as Me₄SiO₄ or Et₄SiO₄, with polyhydric alcs., in varying proportions. The products are said to possess therapeutic properties.

Pyrimidine derivatives. S. J. THANNHAUSER. Ger., 285,286, Apr. 25, 1914. Pyrimidine derivs. are obtained by treating diaminopyrimidines with sugars or other substances containing an aldehyde group, or with the carboxylic acids obtained from such sugars by oxidation.

Salt-like double compounds of the ω -methylsulfonic acid of *p*-aminophenyl salicylate with purine derivatives. J. ABELIN, E. BÜRG and M. PERELSTEIN. Ger., 285,579, May 18, 1913. The double salts are obtained by acting upon an alkali salt of ω -Me-sulfonic acid of *p*-aminophenyl salicylate with a basic deriv. of purine, or upon an alkali compd. of such a purine deriv. with the free ω -Me-sulfonic acid of *p*-aminophenyl salicylate. The purine derivs. specified are 1,3,7-tri-Me-2,6-dihydroxypurine, 1,3-di-Me-2,6-dihydroxypurine. The products, which are readily sol. in H₂O and are suitable for injections, are applicable therapeutically.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

The disposal of niter cake. ANON. *J. Soc. Chem. Ind.* 34, 1121(1915).—A report of the special joint committee of the Chemical Society and the Society of Chemical Industry, appointed to consider the question of utilization of niter cake. The following suggestions were received. Heating the cake with NaCl, collecting the HCl, and afterwards treating the Na_2SO_4 in the black-ash furnace in the usual way. Heating with magnesite to make Epsom salts for use in the textile industries. Replacing H_2SO_4 in the manuf. of superphosphates. Roasting with Fe scale to get off the available acid in its most concd. form. Use in the making and glazing of slag bricks. Sprinkling on manure heaps to fix the NH_3 . Heating with mixed sulfide ores to ext. the Zn. Blowing steam or air into the melt and directing the mixt. of acid vapors into the H_2SO_4 plant. Granulating the melt by pouring into H_2O and centrifuging the grains to obtain a clean Na_2SO_4 and an acid mixt., which can be sprayed into an auxiliary chamber of acid plant, the chamber acid obtained being concd. and used again in the HNO_3 process where a little NaHSO_4 is unimportant. Using the niter cake to increase extn. of Cu when roasting chalcopryrite, by charging into the lower floors of a multiple hearth furnace. Utilizing niter cake as a source of acid for lixiviation of Cu materials, pyrites, cinders, etc. Utilization in the trenches in place of $\text{Fe}_2(\text{SO}_4)_3$. Using the cake instead of H_2SO_4 to decompose soap suds and to liberate free fatty acids instead of discharging into rivers. Using after neutralizing to ppt. $\text{Ba}(\text{SH})_2$ to make blanc fixe and NaSH (cf. U. S. Pat. 714,145). Mixing 1 part of leather-clippings with 2 parts of niter cake and heating to 300° , when much of the N is converted into $(\text{NH}_4)_2\text{SO}_4$; the product is cooled and mixed with 1 part of mineral phosphate and sold as fertilizer. Use as a weed killer; for flushing drains; in place of H_2SO_4 to make "pearl hardening;" roasting with potash feldspar and crystg. out the potash alum. Using it with NaCl for the roasting of Cu, Zn, and Ni ores previous to leaching. Using it in the place of Na_2CO_3 in the manuf. of W powder. Grinding with dry CaCl_2 to produce HCl, and then adding more CaCl_2 to form gypsum. Replacing H_2SO_4 in converting Na_2CrO_4 into $\text{Na}_2\text{Cr}_2\text{O}_7$; for opening up W ores. Neutralizing the free acid, reducing to sulfide by means of fine coal at $600\text{--}850^\circ$, and crystallizing the product. Manuf. of soda alum (cf. U. S. Pat. 714,846). Fusing the cake with sand to produce H_2SO_4 and Na silicate for glass making, etc.

F. W. SMITHER.

Preparation of alkali nitrates from calcium nitrate. H. LECHATELIER AND B. BOGRRCH. *Compt. rend.* 161, 475-9(1915).—A description is given of the prepn. on a commercial scale of NH_4NO_3 from $\text{Ca}(\text{NO}_3)_2$, such as is obtained from Norway. The chief difficulty met with lies in the nature of the pptd. CaSO_4 , but by heating to 150° a mixt. of CaSO_4 and $\text{CaSO}_4 \cdot 0.5\text{H}_2\text{O}$ can be obtained which settles and filters rapidly.

GEORGE W. MOREY.

Internal temperature of sulfur furnaces. STEFANO PAGLIANI. Palermo. *Ann. chim. applicata* 4, 268-70(1915).—A reply to criticisms on a previous article by P. (C. A. 9, 3331).

S. LEVY.

Relations of the inorganic nitrogen compounds to protein and their technical production from coal and the constituents of the atmosphere. A. BAUDREXEL. *Wochschr. Brau.* 32, 264-6(1915); cf. C. A. 9, 2772.—A review of the synthetic manufacture of the different inorganic N compounds and their use for industrial and agricultural purposes.

L. W. HAAS.

The chemical industry of Holland under the influence of the war. ANON. *Chem. Ztg.* 39, 965-6(1915).

J. H. MOORE.

Progress of the inorganic heavy chemical industry in 1913 and 1914. BRUNO WASSER. *Chem. Ztg.* 39, 741-3, 750-4, 782-5, 848-9, 886-9, 902-6, 915-7, 934, 957-61, 967-9, 977-9, 988-9(1915).—A review of conditions, processes and app., with 26 cuts and a bibliography of 1756 references. A special edition of the review may be ordered from *Chem. Ztg.*, Cöthen, Germany. J. H. MOORE.

The royal bureau for testing materials at Lichterfelde-West near Berlin and its problems. WERNER MECKLENBURG. *Naturwissenschaften* 3, 645, 665(1915).—Descriptive. The investigations carried out by this laboratory are similar in nature to those carried out at the Bureau of Standards, Washington. The paper is profusely illustrated. C. G. F.

The gaging of storage tanks. R. L. OGDEN. Rahway, N. J. *J. Ind. Eng. Chem.* 8, 58-9(1916).—Method of solution of the problem of calcg. the vol. of liquid in a cylindrical tank with dished ends, lying on its side, for each inch of depth. F. A. H.

The reciprocal salt pair $\text{KCl} + \text{NaNO}_3 \rightleftharpoons \text{NaCl} + \text{KNO}_3$ and the manufacture of conversion salt-peter (REINDERS) 2.

Nitric acid. NORSK HYDRO-ELEKTRISK KVAELSTOFARTSELSKAB. Brit., 19,792, Sep. 15, 1914. In concg. HNO_3 in counter-current with H_2SO_4 , the requisite temp. is maintained in the concg. tower by introducing the HNO_3 as a mixt. of liquid and vapor preferably produced by boiling the HNO_3 outside the concg. tower. Cf. C. A. 9, 1375.

Ammonia from the elements. BAYER & Co. Ger., 285,698, Jan. 3, 1914. When the ferri- or ferro-cyanic acid salts of the alkali and alk.-earth metals are heated, at first alone with as complete exclusion of air as possible (e. g., in a covered crucible or in a current of gas free from O), and H and N are then conducted over the resulting decompn. products, a union of the gases, to form NH_3 , results, with an exceptionally large yield. The union of the elements is effected with the employment of these catalytic agents, at a relatively low temp. and pressure. E. g., $\text{K}_4\text{Fe}(\text{CN})_6$ is heated at 600-700° in a current of H under atm. pressure. The grayish black roast is placed in a high pressure app., heated to 430°, and upon passing through this mass a N-H mixt. under a pressure of 150 atm., a continuous formation of NH_3 results, yielding 15 vol. % in the escaping gas.

Catalyst for synthesis of ammonia. C. ELLIS. U. S., 1,167,280, Jan. 4. Atomized molten Ce containing La, Yt or Di is intimately mixed with granular charcoal.

Ammonia and carbon compounds containing nitrogen. H. KOPPELS. Ger., 285,354, Sep. 16, 1913. Addition to 257,188 (C. A. 7, 2289). The heating of the nitrogenous masses is effected by means of circulating gases, freed from their NH_3 -content by keeping the content of water vapor as constant as possible.

Titanic oxide. A. J. ROSSI and L. E. BARTON. U. S., 1,166,547, Jan. 4. Ore containing oxides of Ti and Fe is melted with NaOH. The melt is lixiviated to remove excess NaOH and the residue is digested with an amt. of concd. HCl which is proportioned to combine only with the Fe and alkali present. Cold H_2O is added to promote the settling of hydrated TiO_2 , while retaining the other compds. in soln. (the settling being accelerated if desired by adding NaCl) and the ppt. is calcined. The product contains 90-99% TiO_2 .

Pure zinc oxide. W. ASKE. U. S., 1,165,743, Dec. 28. Na_2CO_3 is added to a soln. of Na zincate to ppt. pure ZnO and form NaOH in soln. The ppt. is sepd. and the mother liquor is treated with lime and the resulting CaCO_3 ppt. is sepd. to recover the NaOH in soln.

Aluminium sulfate. J. BOULTON. Brit., 20,227, Sept. 26, 1914. $\text{Al}_2(\text{SO}_4)_3$, free from Fe, is obtained by treating crude material such as bauxite or oxidized shale with H_2SO_4 under the action of electrolysis and magnetism at 100°F ., the liquor being finally filtered and crystd. The electrolysis and magnetism are applied by means of a frame of magnetized steel wires having Cu wire cross-pieces from which hang electrodes of Zn. The whole is immersed in the liquor and is supported on a wooden stool.

Sodium carbonate. M. SPAZIER. Brit., 19,245, Aug. 29, 1914. App. for mfg. soda crystals from soda ash by the process of 29,827, 1913 (C. A. 9, 1673), consists of open tanks in which the soda ash is dissolved in cold H_2O , drainage boards, and reservoirs for receiving the mother liquor from the tanks. The soda ash is preferably fed to the tanks through a screen. The tanks are preferably used alternately, the crystals from one being removed to the drainage board, and the mother liquor to the reservoir while crystn. proceeds in the other tank. The liquor drains back from the drainage boards to the tanks, the liquor is returned from the reservoir through one of the openings closed by screw plugs, and H_2O is added from one of the taps provided for that purpose.

Solid ammonium carbonate. J. BUEB and DEUTSCHE CONTINENTAL GAS-GES. Ger., 285,498, Mar. 22, 1914. Experiments have demonstrated that in the production of sublimed $(\text{NH}_4)_2\text{CO}_3$, if the gaseous components (NH_3 , CO_2 and steam) be intimately mixed before entrance into the sublimation chamber, and heated above the decompn. temp. of the $(\text{NH}_4)_2\text{CO}_3$, the union of the components can be effected in the sublimation chamber. For this purpose, a sufficient amt. of H_2O or NH_3 soln. is placed in the lower portion of the sublimation chamber. The supply pipes for the CO_2 and NH_3 dip into the liquid to a sufficient depth. If, now, the gaseous components are conducted into the liquid in a rapid stream, while at the same time the upper portion of the sublimation chamber is cooled, the H_2O heats up to such a degree that at the surface a rapid sublimation of $(\text{NH}_4)_2\text{CO}_3$ takes place with deposition of the solid salt, in a thick crust, in the upper, cooled portion of the sublimation chamber. The H_2O , as used, may be replenished, either continuously or from time to time, as such or in the form of steam.

Solid ammonium carbonate. J. BUEB and DEUTSCHE CONTINENTAL GAS-GES. Ger., 285,531, Mar. 22, 1914. In previous processes the product obtained is not uniform, for the layers deposited in a disintegrated state in the sublimation chamber show a higher content of $(\text{NH}_4)_2\text{CO}_3$ than those layers produced later in the process and deposited higher up. A solid product, uniform throughout, may be obtained by cooling the upper portion of the sublimation chamber, while supplying heat to the lower portion. In this way the yield of the sublimed product is increased, while at the same time the $(\text{NH}_4)_2\text{CO}_3$ deposits quickly on the walls, so that the period of reaction is shortened.

Apparatus for treating lead ore with nitric acid. S. W. ANDERSON. U. S., 1,165,742, Dec. 28. Stoneware vessels 10, each of which contains a vertical spiral agitator operated by gears 35, 36, are partly filled with galena through the chutes 22

and with HNO_3 from the tanks 14 and the vessels are heated by hot H_2O in the trough 11. Pb nitrate soln. produced is drawn off and purified and N oxides are led off from the tops of the vessels 10 and reconverted into HNO_3 in the tower 25.

Furnace for making sodium sulfate and hydrochloric acid. K. THELEN and F. WOLF. U. S. 1,165,815, Dec. 28. H_2SO_4 , NaHSO_4 and NaCl are heated together

in the furnace to produce HCl . The charge is introduced through the inlet *J* into the mixing vessel *B*. The stirrer *C* when rotated in one direction mixes the charge and when rotated in the opposite direction feeds the charge through the conduit *D* to the calcining furnace where the stirrer *L* and scraper *M* distribute it. Gaseous HCl is led off through the outlet *G* and through another outlet from the furnace chamber.

Anhydrous sodium hyposulfite. E. VON PORTHEIM. U. S., 1,166,160, Dec. 28. A mixt. of Na formate and Na pyrosulfite is reacted on with SO_2 in dil. alc. containing about 75-80% alc. at a temp. of 65-70°.

Barium chloride. E. V. GRANO. U. S., 1,167,061, Jan. 4. Cl gas is passed into a concd. soln. of BaS at a temp. of about 85° and the S and BaCl_2 formed are sepd. by allowing the pptd. S to settle through a perforated false bottom in the reaction vessel.

Continuous production of nitrogen compounds from metal carbides and nitrogen. C. KRAUSS, P. STÄHELIN and AKT.-GES. FÜR STICKSTOFFDÜNGER. Ger., 285,699, June 15, 1913. Addition of 282,213 (C. A. 9, 2298). In order to prevent the reversion of the cyanamide obtained according to the parent process, and to avoid the fusion of the transporting agent, the channel furnace is provided with a regulable external cooling device. The reaction can then, throughout its entire extent, be maintained readily within the temp. limits which are necessary to obviate the difficulties stated. Also practically only the theoretical amt. of N required for the reaction need be used.

Obtaining nitrogen from the air. R. WINNE. U. S., 1,166,294, Dec. 28. Air is led through the inlet *g* into a porous alundum tube 2 glazed at one end 4 and heated throughout most of its length by a resistance wire 3. This tube is maintained at 800-900° and H_2 is supplied through the pipe 12 and passes through a porous sand filling 11 and the wall of the tube 2, forming a mixt. of almost pure H_2O and N which is led off through the outlet 13 and treated to remove the H_2O and other impurities present in small amts.

Catalyst containing copper or nickel. C. ELLIS. U. S., 1,165,956, Dec. 28. A friable mixt. containing non-colloidal $\text{Ni}(\text{OH})_2$ and sol. salts is prepd. from $\text{Ni}(\text{NO}_3)_2$ or $\text{Cu}(\text{NO}_3)_2$ and NH_4OH and employed as a starting material for making a catalyst by drying, washing and reducing with H_2 .

Treating blast furnace slag. T. TWYNAM. Brit., 20,258, Sept. 28, 1914. Molten blast-furnace slag is used for raising steam, *e. g.*, by allowing it to flow into H_2O or by discharging jets of H_2O onto the slag in a closed receptacle, the slag being thereby granulated; the steam is used, as in low-pressure turbines, for the production of high-tension elec. current, which is used to obtain HNO_3 by oxidation of atm. N, the HNO_3 being then used to obtain from the slag $Ca(NO_3)_2$ and other products. The acid should be neutralized by the slag as completely as possible. SiO_2 is sepd. in a gelatinous form, and to the soln., lime or dolomitic lime is added to ppt. the metals other than Ca, the filtrate being $Ca(NO_3)_2$. The ppt. is treated with soda to obtain $NaAlO_2$, from which Al_2O_3 is prepd. by known methods. and the residue, consisting of MgO and MnO , may be used for the production of MgO bricks. Alternatively, the Al_2O_3 may be pptd. first. The $Ca(NO_3)_2$ is evapd. to dryness. It usually contains some potash from the slag, and may be used mixed with $(NH_4)_2SO_4$ or K_2SO_4 as a fertilizer, to which the SiO_2 obtained as above described may be added as a diluent; or the SiO_2 , which usually contains a little $Ca(NO_3)_2$, may be used alone as a fertilizer, or may be used as an ingredient of mortars and bricks.

Absorber for absorption refrigerating machines. A. ZELLNER. Ger., 285,026, Jan. 25, 1914.

Electric insulating materials. W. TRIGGIN and LONDON ELECTRIC WIRE Co. and SMITHS LTD. Brit., 19,878, Sept. 17, 1914. An insulating material for elec. conductors which is not readily combustible consists of strip asbestos coated on one side with an even layer of combed or carded cotton or wool, or a mixt. of cotton and wool, or paper made from manila, wood pulp, hemp, flax, jute, or mixts. of these substances, the whole being impregnated with rubber soln. A machine is specified.

Plastic compositions. A. G. HOPKINS. Brit., 19,437, Sept. 4, 1914. A sol. silicate and pptd. chalk are mixed to produce $CaSiO_3$, which is rendered sticky and non-drying by the addition of molasses or treacle and glycerol or the like. The product may be employed for mending tanks for containing hydrocarbons, etc., or for making liquid-tight joint for use in connection with hydrocarbons, etc. The compn. may be spread upon calico and applied as a patch, or it may be worked into a plug.

Phosphorescent motion-picture screen. A. WRIGHT. U. S., 1,166,569, Jan. 4. The surface of the screen is coated with varnish mixed with willemite or other material which becomes luminescent by the action of light and thus reduces eye-strain in viewing motion pictures by effecting continuous illumination of the screen when in use.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Jena glass and the war. E. ZSCHIMMER. *Chem. Ztg.* 40, 7-8(1916).

J. H. MOORE.

Special glasses and their constituents. A. GRANGER. *Mon. sci.* [5] 5, 274-85 (1915).—A review and discussion (with some analytical data) of the literature under the captions: (a) Ba glass, (b) ZnO in glass, (c) MgO in glass, (d) Al_2O_3 in glass, (e) B_2O_3 , P_2O_5 , Sb, As in glass.

F. W. SMITHER.

The influence of some unusual zinc compounds in a chrome green glass. R. H. MINRON. *Trans. Am. Ceram. Soc.* 17, 667-71(1915).—Various forms of Zn were introduced while Cr_2O_3 was kept const. All ordinary Zn salts were tried in 2 burns: (1) regular kiln, (2) small muffle test kiln. From burn 1 the following conclusions were drawn: (1) no evidence of green color is found in any glaze containing Zn from any source; (2) $ZnCrO_4$ produces strongest color; (3) $Zn_3(PO_4)_2$ produces the strongest pink shade;

(4) most of these salts have not produced good glaze texture; (5) Zn salts not containing O destroy the green color of Cr_2O_3 the same as Zn salts combined with O. From burn (2) the conclusions were: (1) short fire has made much difference in maturity; (2) the short fire changes most of the colors showing more of the green tints.

C. H. KERR.

Causes of stony glass and the relation of potassium carbonate to it. C. J. BROCKBANK. *Trans. Am. Ceram. Soc.* 17, 760(1915).— K_2CO_3 is not ordinarily a cause of stones. One case is cited where K_2CO_3 containing 16% H_2O was replaced by H_2O -free material resulting in a scum which caused some stones.

C. H. KERR.

Causes of stony glass and the relation of potassium carbonate to it. FREDERIC CARDER. *Trans. Am. Ceram. Soc.* 17, 761-3(1915).—The chief cause of stones are: (1) soln. of the pot; (2) slow fusion; (3) imperfect mixing of the batch; (4) too large SiO_2 grains. K_2CO_3 makes glass more liable to stone simply because it is less liquid than Na glass.

C. H. KERR.

Cause and differentiation of seeds in glass. ROBERT L. FRINK. *Trans. Am. Ceram. Soc.* 17, 793-802(1915).—Causes given are: (1) increase in factory production, meaning overworking of the tank; (2) faulty furnace operation. Seeds (or bubbles) are stated to come from: (1) CO_2 and CO from batch materials; (2) smoke or oil vapor; (3) SO_2 or volatilized NaCl; (4) gas evolution accompanying devitrification; (5) arsenic; (6) occlusion of air. Characteristic appearances and methods of occurrence are described.

C. H. KERR.

The silvering of glass. ALEXANDER SILVERMAN AND PAUL D. NECKERMAN. Univ. Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 505-19(1915).—Some historical data are given and a good bibliography. Tabulation of qualitative results is given, using a reducing agent, both hot and cold in each case, both concd. and dil., the reagents and results being briefly as follows (consult original for exact data): (1) Na-K tartrate, good; (2) HCHO, fairly good; (3) tartaric acid, fair; (4) citric acid, poor; (5) dextrin, poor; (6) tannic acid, poor; (7) Na tartrate, fair; (8) milk sugar, fairly good; (9) SnCl_4 , poor; (10) cane sugar, good; (11) phenylhydrazine, poor; (12) HCOOH , poor; (13) KNO_3 , poor; (14) Na_2SO_3 , poor; (15) HNO_3 , poor; (16) FeSO_4 , poor; (17) CH_3CHO , good.

C. H. KERR.

Saggers: past, present, future, their scientific, humanitarian and commercial aspects. J. P. GUY. *Trans. Eng. Ceram. Soc.* 14, 27-37(1914-15).—Saggers should be fired to their max. temp. of use before being put into service. A special material called "aluminous asbestos" from South Africa is highly recommended. This apparently is a waste product (probably the rock matrix) accompanying S. African asbestos. A sample sagger containing this material was exhibited in good condition after 10 burns. Cf. C. A. 9, 1835.

C. H. KERR.

Microscopic investigation of some compounds noted in the systems soda-zinc oxide-silica and soda-zinc oxide-titanic oxide-silica. A. A. KLEIN AND G. H. BROWN. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 745-59(1915).—In melts of that part of the system, Na_2O - ZnO - SiO_2 lying between the following concn. in mol. %: 90.0 SiO_2 , 10.0 ZnO , 10.0 ZnO ; 50 Na_2O , 40.0 SiO_2 ; and 60.0 ZnO , 40.0 SiO_2 , 3 types of structures are encountered, glassy, mat, and cryst. In the mat and cryst. melts, with 1 exception, the compd. which seps. appears to be 2 $\text{ZnO} \cdot \text{SiO}_2$. This closely resembles the mineral willemite in optical constns. Allowing for the chem. inhomogeneity of the glass the max. n follows the Lorentz-Lorenz law of sp. refractivities fairly closely. Glassy, mat and cryst. structures occur in melts of Na_2O - ZnO - TiO_2 -

SiO_2 . Two types of crystals are noted. One type is 2ZnOSiO_2 containing a small amt. of TiO_2 . The compn. of the other type is unknown, but its peculiar optical properties, point to either zinc titanate or TiO_2 .
C. H. KERR.

The physics of the clay molecule. R. F. MACMICHAEL. *Trans. Am. Ceram. Soc.* 17, 616-28(1915).—As a result of several years' exptg. the following statement of the case is made: (1) The strength of clay is due to the mol. cohesion of the clay particles themselves. (2) H_2O when added to a mass of dry clay produces a disruptive force within the mass. (3) Plasticity results from a balancing of the forces of cohesion and disruption. (4) Fluids other than H_2O produce plasticity in clay. (5) Org. matter, sol. salts, sols, and colloids, except as the latter are considered to be merely very fine clay particles, are not essential to plasticity.
C. H. KERR.

Use of sodium salts in the purification of clays and the casting process. A. V. BLENNINGER. Bur. of Standards, *Tech. Paper* 51(1915).—Deflocculation of clays in aq. suspension by use of alkalies permits a more complete sepn. of the fine clay matter from the coarser granular material and a quicker sedimentation of the latter takes place due to the reduced viscosity. The "liquifying" action is due to OH ions from hydrolysis of Na_2CO_3 and Na_2SiO_3 , which repel the clay particles, due to their negative charges, and increase the dispersion. An increase of the alkali beyond the point of max. deflocculation causes coagulation. It may be followed by a second liquefaction, due to absorption of the salts. Org. colloids have a somewhat similar action but also protect the clay particles from the flocculating anions. The presence of chlorides or sulfates of Ca, Mg or Al requires an increased amount of alkali for deflocculation and may prevent max. liquefaction. In using alk. reagents in clay washing a dil. soln. of a definite amt. of NaOH or of Na_2CO_3 and Na_2SiO_3 in equal parts replaces the H_2O used in the blunger. After passing the settling troughs and screening, the slip stands until sufficient sepn. of fine-grained SiO_2 , biotite, etc., takes place. It is then run into another tank, is flocculated with AlCl_3 and filter-pressed. The reagents should not cost over 7-8 cents per ton of clay. In certain fire clays $\text{Na}_2\text{C}_2\text{O}_4$ was a better deflocculator. This washing process greatly improves the color, increases the content of clay substance, decreases the drying shrinkage and tends to increase the burning shrinkage of most kaolinitic clays. It is not successful with clays containing finely divided Fe_2O_3 . The elec. process of clay purification does not result in a product superior to that from the ordinary washing process. Finely divided Fe_2O_3 is not removed, but finely divided quartz in suspension is deposited with the clay on the + electrode. The electrical process itself is a mechanical separation having the same function as the filter press. The preliminary sedimentation by use of electrolytes is the real purification feature of the process. The viscosity of clay slips and casting slips is detd. with a flow viscosimeter in the Mariotte tube principle. Na_2SiO_3 is more effective than Na_2CO_3 in reducing viscosity. N. C. kaolin slips are not markedly affected by these reagents due to coarseness; Georgia kaolin shows a well defined min. viscosity of short range; Tenn. ball clay No. 3 and Florida kaolin show no well defined min. viscosity. A large vol. of air is absorbed in clay slips, removal of which increases the viscosity. Interaction occurs between different clays in slips independently of alk. additions, which may considerably influence their behavior in casting. The ball clay should be reduced to a min. in casting slips. The absorption of NaOH by clays is greater than that of Na_2CO_3 . The tensile strength of cast bodies containing alkali additions may be greater than that without alkalies and the strength with max. deflocculation does not seem to be less than with a less addition of alkali. The formula, $n_1 = n(1 + Kf)$ is suggested for interpolation purposes for const. alk. additions. Casting bodies with low additions of alkali are more likely to change in viscosity with time than those containing larger amounts.
R. K. HURSH.

Notes on German clayworking plants. T. W. GARVE. *Trans. Am. Ceram. Soc.* 17, 592-605(1915).—Descriptive. C. H. KERR.

The testing of clay. R. F. MACMICHAEL. *Trans. Am. Ceram. Soc.* 17, 639-59 (1915).—Details of the ordinary physical tests are given, describing some new modifications of app. C. H. KERR.

Factory practice in the casting of clay ware. A. V. BLEININGER, T. G. McDUGAL, R. C. PURDY, *et al.* *Trans. Am. Ceram. Soc.* 17, 691-6(1915).—Unless the slip is beaten up vigorously when mixed it will change on standing, especially after the first 24 hrs. Even if well beaten some changes occur during the first day. Temps. also are very important. The thicker the wall of the ware to be cast the greater the amt. of electrolyte needed. C. H. KERR.

A study of earthenware bodies. I. LIONEL J. TRUSS AND P. STANWAY. *Trans. Eng. Ceram. Soc.* 14, 173-5(1914-15).—To find the difference in behavior of china clay and ball clay in their effect on crazing and peeling when used in earthenware bodies, mixtures were made of all compns. in 10 and 15% steps from 0 to 85% each of clay, feldspar and quartz, $\frac{1}{2}$ of the clay being ball clay and the other half china clay. The results are shown in the accompanying triaxial diagram. C. H. KERR.

A study of fire clay, shale and surface clay mixtures with reference to their porosity-temperature relations. G. H. BROWN. Bur. Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 451-8(1915).—When shales or surface clays are mixed with fire clays the impure clays retain their characteristic tendency to overburn, but the temp. of overburning is increased with increasing amts. of fire clay. Intimate grinding would probably change these results. Addition of 10-30% fire clay to surface clays, or shales, improves their vitrification behavior but increased burning temp. is necessary. C. H. KERR.

The relation between the modulus of elasticity and the porosity of burned clay. A. V. BLEININGER AND G. H. BROWN. Bur. Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 464-70(1915).—Two No. 2 fire clays, 2 paving brick shales and 3 surface clays were tested. The modulus of elasticity was found to be a function of the porosity, each clay having its own characteristic porosity-modulus curve. With shales the modulus of elasticity increased gradually from max. porosity, remained const. during vitrification and rose rapidly when complete vitrification was reached. The marked difference in the value of modulus of elasticity favoring paving brick shales indicates the possible application of such data in estg. toughness. C. H. KERR.

The effect of lime on certain cracking clays. N. B. DAVIS. *Trans. Am. Ceram. Soc.* 17, 497-504(1915).—Preheating is usually too costly. In agriculture lime is used to granulate soils. The same idea may be applied to clay working. Adding Kelley Island hydrate to 4 clays which cracked in drying, the trouble was overcome with 3, 4, 6 and 12%, resp. Analysis of clays shows low CaO in clays which crack. The

effect of the lime is to form Ca salts with the acid silicates and silicic acid. Clay should be ground to 15 mesh and hydrate mixed in dry before using. C. H. KERR.

The deformation of plastic bodies under compression as a measure of plasticity. WARREN E. EMLY. U. S. Bur. Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 612-5 (1915).—Working with hydrated limes, samples were molded into cylindrical form and placed on the pan of a Troemner soln. balance. The top head could be adjusted to place. Load was applied upward by placing wts. on the beam and any deformation previous to rupture was taken up by lowering the top head. Measurements were made of load area and the angle of the plane of rupture was measured by a comparometer. With 31 samples the order agreed well with practical comparisons. Thus a sticky, high-CaO hydrate showed a value of $n = 0.8$, $S_0 = 17.5$; a dolomitic hydrate of excellent plasticity showed $n = 0.56$, $S_0 = 32.5$; and a short, sandy hydrate showed $n = 0.44$, $S_0 = 17.0$. n is the coeff. of internal friction and S_0 is the force of cohesion between the particles, these being calcd. from the formula: $S_0 = S \tan \theta/2n$. With clays the 2 chief objections are: (1) the load should be increased continuously rather than by adding 100 g. every 30 secs.; (2) difficulty of applying the load exactly parallel to the axis of the cylinder. An improved machine is being built. C. H. KERR.

The effect of salts on the drying behavior of some clays. HOMER F. STALEY. Iowa State College. *Trans. Am. Ceram. Soc.*, 17, 697-719 (1915).— Na_2CO_3 usually decreases the rate of drying, increases the tendency to crack and lengthens the vitrification range. It is seldom of commercial value. NaCl decreases rate of drying, usually increases shrinkage and helps color and vitrification behavior. The use of 1/4-2% NaCl is a feasible method of rendering workable certain Iowa clays, which crack in drying and burning. The use of MgSO_4 or CaSO_4 is objectionable because of harmful effects in the burning. Reduction of cracking by certain salts is due to coagulation and the production of a structure favorable to capillary action which permits H_2O to be drawn from the interior as rapidly as it evaps. from the surface. C. H. KERR.

Some casting slip troubles. J. A. AUDLEY. *Trans. Eng. Ceram. Soc.* 14, 151-63 (1914-15).—A review of Ger. publications. [Cf. *Keram. Rundschau*, are 22, 317 (1914).] Usually the very plastic clays are but little affected by alkali and they therefore not well adapted for use in casting. Often the presence of very fat clay is the cause of poor casting results. Adding scrap clay helps to correct the trouble but is apt to bring in dirt. The Na_2CO_3 added is commonly regarded as the cause of dark stains on the ware. Repeated use of the plaster molds may have some connection because of sol. salts evapd. on the surface of the dried molds. Fe rust from blunger and other vessels containing the slip must be avoided. Hard spots in the molds absorb H_2O more slowly and leave moist patches which show different structure. The most likely theory of the discoloration is that in pouring the slip into the mold a thin layer of raw clay particles remains sticking to the mold at the point of pouring, while the non-plastic ingredients rebound and are washed away, thus causing difference in body compn. Very low calcination of part of the mix may be helpful. Cf. C. A. 9, 1835. C. H. KERR.

Slip weight and specific gravity of solutions of water glass. H. STEELE AND J. W. MELLOR. *Trans. Eng. Ceram. Soc.* 14, 164-6 (1914-15).—The object was to find the relation between sp. gr. and dry silicate content of water glass so as to standardize additions to casting slips. Detn. showed that the wt. of dry silicate (in oz. per pint of liquid) = $(1.33 \times \text{oz. per pint wet wt.})$ minus 27.8. A complete table is given. C. H. KERR.

Some notes on hard or felspathic porcelain. J. W. MELLOR. *Trans. Eng. Ceram. Soc.* 14, 176-92 (1914-15).—No ware is made in England. The chief Eng. raw material

not used in Germany is Cornish stone. Standard types of bodies are given as follows: Standard porcelain: clay 50, feldspar 25, quartz 25; insulator body: clay 51, feldspar 43, quartz 6; mortar body: clay 62, feldspar 21, quartz 17; parian body: clay 40, feldspar 58, quartz 2. The analysis of a number of German porcelains shows that they vary between these limits: clay 42-66, feldspar 18-35, quartz 12-30. The old French and Berlin bodies contained, resp.: clay 42, 53, feldspar 25, 27, quartz 33, 20. Seger porcelain (low firing) is made of: clay 25, feldspar 30, quartz 45. A body used near Limoges which is fairly translucent at cone 11 contains: clay 43, feldspar 27, flint 30. Berlin body for chem. ware contains: clay 75, feldspar 23, flint 20. Eng. ball clay spoils translucency and the china clays are not plastic enough. Ball clay must be kept low and casting may be necessary on account of low plasticity. Ageing is necessary if the ware is to be thrown or pressed and perhaps introducing tannin, etc., might be helpful. With hard porcelain the glaze burning is at higher temp. than the biscuit. It is often done in double deck kilns, the glaze below and biscuit above, the waste heat from the glaze section being used in burning the biscuit above. Marquardt porcelain analyzes between 30 and 35% SiO_2 with 60-65% Al_2O_3 . The tubes are suspended vertically in the oven for firing. Hard porcelain glazes have the formula of cone 4 softened with 0-0.3 BaO and 0-0.3 MgO. The variation is usually: 0.1-0.3 K_2O , 0-0.3 MgO, 0-0.3 BaO, 0.4-0.7 CaO, 0.4-1.2 Al_2O_3 , 3.5-11.0 SiO_2 . With the RO just given the maturing temps. with varying Al_2O_3 (a) and SiO_2 (b) are as follows: 0.4 (a), 3.5 (b) cone 7; 0.5 (a), 4.5 (b) cone 9; 0.6 (a), 5.5 (b) cone 10; 0.7 (a), 6.5 (b) cone 11; 0.8 (a), 7.5 (b) cone 12; 0.9 (a), 8.5 (b) cone 13; 1.2 (a), 11.0 (b) cone 16. The atm. of the hard porcelain kiln is usually reducing. C. H. KERR.

Experiments in casting heavy pieces of porcelain for electrical purposes. HUGO J. LUNDGREN. *Trans. Am. Ceram. Soc.* 17, 627-38(1915).—Sp. gr. of 1.82-1.85 gave the best results for the casting of large wares. One objection found was the presence of small blisters near the surface. C. H. KERR.

Coloration of porcelain. S. T. WILSON. *Trans. Eng. Ceram. Soc.* 14, 213-5 (1914-15); cf. Bernard Moore also S. T. Wilson, *Trans. Eng. Ceram. Soc.* 1905.—President's address. C. H. KERR.

Cobalt and nickel colors. A. D. HOLLINSHEAD, J. TURNER AND J. W. MELLOR. *Trans. Eng. Ceram. Soc.* 14, 167-72(1914-15).—Mixts. of Co and Ni with Zn and Al_2O_3 calcined at cone 10, wet ground, sieved through 200-mesh and dried, were printed on standard earthenware slabs. The colors were hardened on at a dull-red heat, and dipped (a) in standard leadless glaze, (b) in standard raw-lead glaze, and (c) in the same as (b) but converted into a low soly. glaze. The Thenard's blue tint of the Co_2O_3 - Al_2O_3 -ZnO colors is unstable when heated in the vicinity of free SiO_2 , Pb glazes, etc., for it passes into the violet-blue characteristic of Co silicate. Violet-blue is the equil. tint of Co blues, under Pb glazes and leadless glazes. Anything that favors the attack of SiO_2 or glaze hastens the change from the mat blue to the equil. tint. The tint of the mat blue is very sensitive to the compn. of the glaze, high Al_2O_3 glazes low in Pb() favor the color, while high PbO glazes and glazes with vigorous solvent action on the body rapidly change the color to the equil. tint. This shows why the flux on underglaze mat blues must be low, and why the color must be worked as dry and as high in Al_2O_3 as possible. The color must be protected from the solvent action of the glaze. Ni colors were all unsatisfactory, being too unstable. C. H. KERR.

Experiments to overcome scumming and improve the color of brick. A. E. WILLIAMS. *Trans. Am. Ceram. Soc.* 17, 764-70(1915).—The expts. are summarized as follows: (1) treating the surface of a stiff-mud clay column with FeSO_4 did not markedly effect the color in burning; (2) treatment with Fe_2Cl_6 helped the color, evidently by removing the scumming, but as results in commercial kilns have been

obtained; (3) MnCl_2 , volatilized in brick kilns at the finish of a burn, produced dull black colors with but little previous flashing of the kiln; (4) CuCl_2 darkened the color very slightly.

C. H. KERR.

Strength tests of Oregon building brick. IRA A. WILLIAMS. *Trans. Am. Ceram. Soc.* 17, 660-6(1915).—Samples were tested from 29 firms, 15 stiff mud, 13 soft mud and 1 dry pressed brick. Soft mud bricks (a) and stiff mud bricks (b) showed the following range of properties: absorption (a) 17.4-49.6, (b) 9.5-28.7; modulus of rupture, (a) 207-732, (b) 163-1340; compressive strength tested dry, (a) 1186-3524, (b) 1386-9038; compressive strength tested wet, (a) 1151-3327, (b) 1429-8670.

C. H. KERR.

Note on the silica bond in sand-lime brick. W. E. EMLEY, A. A. KLEIN AND E. M. SANBORN. *Bur. Standards, Pittsburgh. Trans. Am. Ceram. Soc.* 17, 471-3 (1915).— H_2S soln., CH_3COOH and alc. are unsatisfactory as solvents to recover the free CaO . Any attempt to dissolve the free CaO must result in partial decompn. of the silicate no matter how weak the acid used. Results of Parr and Ernest are, therefore, unsatisfactory (cf. *C. A.* 5, 3886; *Illinois State Geol. Surv.*, *Bull.* 18).

C. H. KERR.

Choice of raw material for the manufacture of silica (dinas) bricks. A. K. KHOETSKY. *Rev. soc. russe de metall.* 1, 170-202(1914); *Rev. Metal.* 12, 143-5; *J. Soc. Chem. Ind.* 34, 1055.—The value of natural SiO_2 for the manuf. of bricks is detd. by the chem. purity, size of grain obtainable, and the smallness of the increase in vol. on being heated. To withstand a temp. of 1700° the brick must contain not less than 96% SiO_2 , this condition requiring that the raw material must contain 98% SiO_2 . The raw material must not give too fine a powder on crushing, as bricks composed of fine grains are not sufficiently porous, and break down on being heated. As regards the 3rd factor, the order of merit of the natural forms of SiO_2 is given as follows: Chalcedony, plutonic quartzites, quartzite derived from vein quartz, vein quartz. The 2 latter forms contain a modification, α , which passes on roasting into a second modification, β , with increase of vol. Schistose quartz, sandstones, and sand are unsuitable for the manuf. of bricks, the first on account of its structure and the presence of many impurities in the form of inclusions, the two latter on account of their variability of compn. and their too great fineness after being ground.

H. J. C.

Classification of floor tiles as related to degree of vitrification. FORREST K. PENCE. *Trans. Am. Ceram. Soc.* 17, 484-92(1915).—The following is offered as a basis of classifying all floor tiles not obviously belonging to special types. "The class to which floor tiles shall be assigned shall be detd. by the amt. of H_2O they will absorb. Absorption shall be detd. by immersing the tile in boiling H_2O for 1 hr., followed by soaking in the same H_2O for 24 hrs. Av. results shall be obtained from no less than 5 tiles and shall be expressed in terms of % of the dry wt. Classes of tiles shall be defined by the amt. of absorption as follows: absorption 0-2%, vitreous; 2-10%, semi-vitreous; 10 or more %, plain unglazed."

C. H. KERR.

Oxide of lead versus carbonate of lead in glazes. ARTHUR S. WATTS. *Ohio State Univ. Trans. Am. Ceram. Soc.* 17, 474-83(1915).—The lowest PbO content is possible when litharge is used, the increase being very slight in using Pb_2O_3 and quite appreciable in using PbCO_3 .

C. H. KERR.

Note on pros and cons of use of zinc oxide in glazes for semi- and vitrified China bodies. ROSS C. PURDY. *Norton Co., Worcester. Trans. Am. Ceram. Soc.* 17, 520-6(1915).—The advantages of ZnO are: (1) improved color; (2) improved gloss; (3) absence of egg shell finish; (4) less crazing; (5) greater heat range, thus decreasing requirement of PbO and B_2O_3 . The disadvantages are: (1) decreased range of possible

color; (2) soln. of ZnO glaze in caustic washing solns. used at hotels, etc. The use of ZnO for cheaper wares is recommended; for vitrified goods it should be omitted.

C. H. KERR.

Galena and lead-bearing waste materials as glaze ingredients. JULIUS MILLER. Ohio State Univ. *Trans. Am. Ceram. Soc.* 17, 779-92(1915).—Suggestions applicable to cheap ware are offered.

C. H. KERR.

Notes on the burning of salt-glazed sewer pipe. GEORGE D. MORRIS. *Trans. Am. Ceram. Soc.* 17, 606-11(1915).—Water smoking (up to 177°) must be slow to avoid scaling, blistering and cracking. The heating up (177-427°) may be rapid if other precautions are taken. The oxidation (427-760°) must be slow if the clay is high in C. Vitrification (760-1149°) is commonly carried to a point where draw trials show a glassy fracture, if broken while hot. Salt glazing should be done when the fires are clean and the draft good but not excessive. Details of control are given.

C. H. KERR.

Quarry tile. C. P. OUDIN. *Trans. Am. Ceram. Soc.* 17, 777-8(1915).—A steam sewer pipe press is now used.

C. H. KERR.

Protective coating for dryer cars. M. C. BOOZE. Univ. Ill. *Trans. Am. Ceram. Soc.* 17, 727-44(1915).—Bakelite is recommended.

C. H. KERR.

Bauxite: a source of aluminium. ANON. *Engineering* 100, 625-6(1915).—A general article in which are discussed the occurrence and properties of bauxite and its use as a refractory lining for cement kilns and metallurgical furnaces, particularly lead furnaces.

E. H.

Data on the effect of pressure applied to a dust body. C. W. PARMELEE. *Trans. Am. Ceram. Soc.* 17, 459-63(1915).—With increase in pressure the d. of the mass increased rapidly up to a certain point which varied with different materials, but beyond that point increase in pressure did not produce a proportionate or even material increase in d.

C. H. KERR.

Progress in economy and efficiency in firing. The Dressler tunnel oven. P. O'H. DRESSLER. *Trans. Am. Ceram. Soc.* 17, 527-48(1915); cf. following abstract. —Data are given from a large up-draft kiln in Staffordshire holding 1300 tons of ware and requiring 1600 tons of fuel, which is 26% of the wt. of ware and saggars, or 121% of the wt. of the ware alone. Since 3.5% of the wt. of the ware is the theoretical fuel requirement, this means that only 2.9% ($3.5 \div 1.21$) of the heat of combustion was used in heating the ware. The wastage was 97%. Ring and tunnel ovens are described. Advantages claimed for the Dressler tunnel oven are: (1) stationary heat zone, saving fuel and repairs; (2) exhaust gases are cooled to 200-250°; (3) recuperation of the heat from cooling ware is used for burning gas and a large excess is available for drying, etc.; (4) skilled labor is unnecessary; (5) freedom from combustion gases surrounding the ware; (6) no saggars are required; (7) uniform heat distribution; (8) absence of dunting troubles; (9) absence of second quality ware; (10) allowable decrease in factory stocks because of short time required for burning.

C. H. KERR.

Development of the Dressler tunnel oven since 1911. CONRAD DRESSLER. *Trans. Eng. Ceram. Soc.* 14, 41-61(1914-15).—The novelty lies in keeping the flame away from the goods inside suspended chambers so arranged that the heat reaches the goods by convection of hot air or by radiation from the chamber surfaces. In July, 1912, at the Barrett Plant, fuel consumption with the Dressler oven was 4256 lbs. of coal per 24 hrs. to burn 10.5 tons of ware and supports to 1050° (17.5%). The latest plan at Barrett's has been in use for 1 yr. and is satisfactory. To correct dunting (due to ware coming out too hot) the direction of travel of the air beyond the hottest point has been reversed. Architectural faience may be cooled from 1050° to correct handling temp. in 8 hrs. This cooling and using the heat elsewhere reduced fuel consumption

from 17.5 to 12.5%. By using a hollow refractory lining, softening of the refractory was prevented and 1250° can be attained. With latest improvements coal consumption will be reduced to 5% of the wt. of ware and supports. Recent work with driers is described.

C. H. KERR.

A gas-fired frit crucible furnace. J. H. SINGLETON. *Trans. Eng. Ceram. Soc.* 14, 38-40 (1914-15).—The crucible has a bib at the bottom so arranged that the metal may be tapped from the bottom as in cupola practice. A temp. of 1650° is attainable.

C. H. KERR.

Veritas firing disk. ROSS C. PURDY. Norton Co., Worcester. *Trans. Am. Ceram. Soc.* 17, 493-6 (1915); cf. *C. A.* 8, 3713.—Correction is made of a mistaken understanding that veritas disks are made from Cook Pottery Co. body. Pottery materials, however, are used. Analysis of a disk showed: Al_2O_3 , 20.98; Fe_2O_3 , 1.18; SiO_2 , 67.48; TiO_2 , 0.40; CaO , 0.44; MgO , trace; Na_2O , 0.43; K_2O , 1.69; ignition loss, 6.80%. This shows clay, feldspar and flint as the probable raw materials. The disks have value in studying the rate of burning.

C. H. KERR.

Electrically heated enamelling ovens. C. W. BARTLETT. *Gen. Elec. Rev.* 18, 1130-6 (1915).—This type of oven insures greater production with a lower unit cost, it permits of utilizing a positive heat control, eliminates the danger of explosions and produces a better enamel. Practically all thermal energy is applied in useful work and a uniform heat radiation results. The revolving type of oven takes little space compared with the output, the baking can go on while work is being put in and taken out, and it is unnecessary to cool down the oven every time a charge is made. In the drawer type, the work is placed in a carriage and pushed into the oven. Enamels may be hardened at 71° in about $\frac{1}{4}$ the time consumed by air-drying methods. Enamels requiring high temp. for baking are hardened in a short time with no danger of explosion. This advantage increases with temp. As temp. rises rapidly there is less danger of overheating of the products.

W. H. BOYNTON.

Titration of calcium oxide or hydroxide in the presence of some aluminates or silicates (EMLEY) 7. Electrical pyrometry (PAUL) 1.

Glass. J. O. MEARA. U. S., 1,166,922, Jan. 4. Illuminating glass is made by fusing together sand 100, Al_2O_3 30, PbO 22, silex 12, soda 37, borax 6, As_2O_3 3, Sb_2O_3 1.25, NaCl 1.5, saltcake 1.5, cryst. Na_2SO_4 2 and gypsum 1.5 parts. The heating is stopped when the specks in the mixt. are practically all eliminated and before the glass becomes clear, thus producing a translucent glass.

Refractory furnace lining. T. A. R. W. TORSÉN. U. S., 1,167,135, Jan. 4. "Carborundum fire sand" 40-50, is mixed with fire clay 15-25 and SiO_2 33-48 parts, using a binder of molasses and H_2O .

Base-exchanging bodies. PERMUTT AKT.-GES. Brit., 20,144, Sept. 24, 1914. Base-exchanging bodies prep'd. by pptn. are filtered, incompletely lixiviated, and dried in the form of press-cakes at a temp. below 100°. A white stony mass is produced, which, on hydrating with cold or hot H_2O , breaks up into hard transparent pieces. Cf. *C. A.* 9, 1235.

Base-exchanging bodies. PERMUTT AKT.-GES. Brit., 20,145, Sept. 24, 1914. The process of converting gelatinous zeolitic ppts. into granular form described in 20,144 1914 (*supra*) is varied by employing high pressure in the production of the press-cakes which yield, on drying, a material which is as hard as glass and breaks up into granular form on hydrating.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

A brief observation on the paper by G. A. Rankin on the ternary system lime-silica-alumina. ERNST JÄNCKE. Hannover. *Z. anorg. allgem. Chem.* **93**, 271-2 (1915).—J. comments on the fact that R. does not give the compd. $8\text{CaO} \cdot 2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3$ as one of the solid phases occurring in the system $\text{CaO}-\text{Al}_2\text{O}_3-\text{SiO}_2$, and affirms the belief that such a compd. exists. An error in the arrangement of the boundary curves is pointed out. Cf. *C. A.* **9**, 702.

GEORGE W. MOREY.

Study of the most fusible mixtures of $\text{K}_2\text{O}-\text{CaO}-\text{Al}_2\text{O}_3-\text{SiO}_2$. HAROLD H. HANNA. *Trans. Am. Ceram. Soc.* **17**, 672-90 (1915).—The following raw materials were used com. feldspar, kaolin and flint (analyses are given). *Kaolin-feldspar*. Mixts. with 0-20% kaolin were made into cones and fused. Results were not entirely clear but the eutectic was very close to 8% kaolin, 92% feldspar. *Feldspar-ball clay*. The same % eutectic was found at 8% ball clay, 92% feldspar. *Feldspar-quartz*. There was a eutectic at 4% quartz. Rankin and Wright (cf. *C. A.* **9**, 702) gave 1165° as the m. p. eutectic between pseudo-wollastonite, anorthite, and tridymite, the compn. being 23.25 CaO, 14.75 Al_2O_3 , 62.0 SiO_2 . Deformation point of cones with ranges and compn. covering this point showed this to be the deformation eutectic as well as the actual m. p. eutectic. Expressed in mol. form this eutectic is 1.00 CaO, 0.348 Al_2O_3 , 2.489 SiO_2 . Trials were then made with all mixts. of the 3 eutectics: (1) 96% feldspar, 4% quartz; (2) 23.5 CaO, 14.75 Al_2O_3 , 62.0 SiO_2 ; (3) 92% feldspar, 8% kaolin. The first to deform was: 0.6 K_2O ; 0.4 CaO; 0.739 Al_2O_3 ; 4.829 SiO_2 . The next to deform was: 0.6 K_2O ; 0.4 CaO; 0.777 Al_2O_3 ; 4.830 SiO_2 . The third to deform was: 0.6 K_2O ; 0.4 CaO; 0.8114 Al_2O_3 ; 4.824 SiO_2 . The only difference in these 3 compns. is in Al_2O_3 . The lowest fusing point mixture of K_2O , CaO, Al_2O_3 and SiO_2 is: 0.60 K_2O , 0.40 CaO, 0.739 Al_2O_3 , 4.829 SiO_2 , which starts to deform with Seger cone 3 but is completely deformed when cone 3 is only $\frac{3}{4}$ down.

C. H. KERR.

The influence of temperature on the strength of concrete. A. B. McDANIEL. Univ. Illinois Eng. Expt. Sta., *Bull.* **81**, 24 pp. (1915).—Under standard conditions at temps. of $150-210^\circ$ the compressive strengths of concrete after 7, 14, and 21 days are approx. 50, 75 and 90% of that after 28 days. After 7 days at $15-21^\circ$ it has twice the strength of concrete kept at $0-4^\circ$.

H. L. OLIN.

Testing of Eisen portland cement in comparison with portland cement. Supplement 2. M. GARY AND H. BURCHARTZ. *Mitt. Materialprüfungsamt.* **33**, 29-34; *Chem. Zentr.* 1915, II, 492.—The results of tests on the 10 yr. old specimens are added to the results of previous tests. Cf. *C. A.* **7**, 1273.

J. C. EVANS.

The rusting of iron reinforcement in concrete. W. ROEDER. *Tonind. Ztg.* **39**, 106-7 (1915).—Two samples of concrete were made with cement from the same factory, but the Fe in one rusted while the other was clean. Analyses showed the cements to be similar except that the one in which the Fe did not rust contained sulfides, while the other did not. R.'s explanation is that the sulfides combine with dissolved O_2 in any H_2O which penetrates the concrete and thus protect the Fe. W. L. BADGER.

Compressive strengths of portland cement mortars and concretes. R. J. WIG. G. M. WILLIAMS AND E. R. GATES. *J. Frank. Inst.* **180**, 608-13 (1915); *Tech. Paper Bur. Standards* 58.—A collation and study of about 20,000 tests of mortars and concretes, from which it is concluded that the compressive strengths of concrete are as much affected by workmanship and use of the proper amt. of H_2O , as they are by the use of the proper amt. of cement. Compressive strengths may be greatly reduced if there is exposure to relatively dry atms. after fabrication. The value of fine aggregates can only be detd. by testing in the combined state with coarse aggregates. Coarse

aggregates must be tested to det. what % gives max. density and no type of aggregate is superior to all other types. Density is a good measure of the relative compressive strengths of different mixes of the same aggregate, but two concretes of the same density composed of different aggregates may vary widely in their compressive strengths. No definite relation exists between gradation of aggregates and compressive strengths, which is applicable to a number of different aggregates. With the relative vols. of fine and coarse aggregate fixed, the compressive strengths increase, directly, though not in the same proportion as the cement content is increased. A. J. PHILLIPS.

The properties of lime from limestone containing magnesia. CHEM. LAB. FÜR TONIND. Berlin. *Tonind. Ztg.* 39, 518-9(1915).—A limestone (a) and the commercial CaO from it (b) had the following compn.: CaCO_3 , (a) 45.98, (b) 34.02; MgCO_3 , (a) 36.64, (b) none; MgO , (a) none, (b) 21.26; Ca(OH)_2 , (b) 15.62. To ascertain whether the MgCO_3 could be decomposed without also decomposing the CaCO_3 , the stone was burned in the lab. at cones 022, 015a, and 010a. At the lowest temp. none of the CaCO_3 and about half the MgCO_3 was decomposed; at cone 015a, all the MgCO_3 and about $\frac{1}{2}$ the CaCO_3 ; and at the highest temp. only 5% CaCO_3 was left. Mixts. were made of coarse CaCO_3 and fine MgCO_3 , and of coarse MgCO_3 and fine CaCO_3 . Sep. portions of each mixt. were burned at the cones above mentioned, sepd. by screening, and the coarse and fine CaCO_3 from each temp. mixed, the MgCO_3 being similarly combined. At cone 022, $\frac{2}{3}$ of the MgCO_3 and none of the CaCO_3 was decomposed; at 015a, 1% of the CaCO_3 and 90% of the MgCO_3 was decomposed, and at 010a $\frac{2}{3}$ of the CaCO_3 and all the MgCO_3 . The material burned at the 2 lower temps. was inert to H_2O , the CaO from cone 010a slacked instantly and was set after 4 days, while the MgO began to slack after 2 hrs. and was set after 4 days. W. L. BADGER.

Note on Estrich plaster. R. K. HURSH. Univ. Illinois. *Trans. Am. Ceram. Soc.* 17, 549-56(1915).—Two rocks ("S" a very pure rock and "O" with about 15% impurity) were burned at 100° temp. intervals from 600 to 1100°, 5 hrs. being allowed at the finishing temp. of each burn. Samples were then ground to 100-mesh, mixed with H_2O and made into briquets. These were placed in a moist chamber for 24 hrs. and later kept moist until tested. Samples burned up to 800° were smooth working but those heated at 900° and above seemed sandy. Burning at 600° (both "S" and "O") gave plasters that did not harden in 7 days. A portion of this soft material from "S" burned to 600° was placed under the microscope with a little H_2O and showed slow crystn. of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. Burns at 700° gave the best strength for both "S" and "O," this being a much lower temp. than is usually quoted. This may be due to the duration of the heat treatment which was very long in comparison with factory work or usual tests. C. H. KERR.

Mortars from a Roman hunting villa. CHEM. LAB. FÜR TONIND. Berlin. *Tonind. Ztg.* 39, 557-8(1915).—Analyses are given of 5 mortars dating from the time of Constantine. Masonry was set in a 1:3 mortar from a slow-setting dolomitic lime with the addition of ground brick. Plaster was about 1:4 without the brick dust. Mosaics were set in a straight lime paste with a little brick dust. In the heating flues was a 1:2 plaster, the CaCO_3 of which was crystallized as aragonite and calcite. All the limes contained considerable MgO. W. L. BADGER.

The valuation of sand and gravel. ANON. *Tonind. Ztg.* 39, 583, 588.—Specifications of screen analyses for sand and gravel for different purposes. W. L. B.

Report of committee on wood block paving. C. H. TRESDALE. *Proc. Am. Wood Pres. Assoc.* 1916, 5 pp.—A specification is offered, covering selection, treatment and laying of wood paving blocks. GEO. M. HUNT.

Report of special committee on specifications for preservative for wood paving blocks. *Proc. Am. Wood Preservers' Assoc.* 1916 (advance copy).—The committee

makes the following recommendations: The preservative shall be wholly derived from coal-gas tar or coke-oven tar; d_{40} shall not be less than 1.06 or more than 1.12; substances insol. by hot continuous extn. with C_6H_6 and $CHCl_3$ shall be not over 3%; when distd. as specified there shall be not more than 5% up to 210°, not more than 30% up to 235°, not less than 35% nor more than 70% up to 315°, not less than 65% up to 355°; $d_{15.5}^{38}$ of distillate between 235° and 315° shall be not less than 1.02, between 315° and 355° not less than 1.08; specific viscosity (Engler) at 82° shall be not over 1.3; not over 3% of water shall be present and not over 2% of dirt shall be allowed to accumulate during treatment. Method of analysis is specified. In the discussion the authors stated that this specification would permit the use of a pure distd. creosote, or mixts. containing up to about 35% of low carbon tar.

GEO. M. HUNT.

Methods of creosoting Douglas fir timbers. O. P. M. GOSS. *Proc. Am. Wood Preservers' Assoc.* 1916 (advance copy).—The "boiling" and "steaming" processes for creosoting D. fir weakened structural timbers 33 to 35% (cf. C. A. 10, 108). The "boiling under vacuum" process, a modification of the Boulton process, has been developed to prevent this. In it the timber is heated in creosote at atm. pressure at 87.7° for 5 to 6 hrs., then a vacuum is drawn through a condenser, gradually increasing to 24 to 27 inches while the temp. of the oil is kept constant. The vacuum is maintained until the water condensed amounts to not over 0.1 lb. per cu. ft. of wood per hr. (usually 12 to 16 hrs.), after which pressure is applied for 4 to 6 hrs., reaching a max. of 120 to 135 lbs. per sq. in. Strength tests on 16 pairs of matched bridge stringers, of which 1/2 were untreated and 1/2 treated by the "boiling under vacuum" process, showed on the av. that the treated material was 99.2% as strong in modulus of rupture as the untreated. Tables of strength values are given.

GEO. M. HUNT.

Overcoming scumming and improving the color of brick (WILLIAMS) 19. Strength tests of Oregon building brick (WILLIAMS) 19. Silica bond in sand-lime brick (EMLEY) 19. Penetration test for asphalts and asphalt cements (HUBBARD) 22.

Preserving wood. W. D. CLARK. U. S., 1,165,753, Dec. 28. Penetration of a preservative such as creosote into the wood is controlled by coating the wood with a mixt. of MgO , Mg silicate and $MgCl_2$ to exclude the preservative from portions where its penetration is not desired, *e. g.*, in treating piling. The wood may first be boiled in the preservative to season it and again treated with the preservative under pressure after application of the coating mixt.

Preserving wood. A. V. ST. ARMANDE. Brit., 20,260, Sept. 28, 1914. Wood is preserved by treatment with dichlorobenzene or other chlorinated deriv. of benzene applied in molten condition or in soln. Oils, waxes, resins, other known preservatives, or other substances may be added.

Seasoning wood. A. P. DERBY and J. H. DARGIE. U. S., 1,166,819, Jan. 4. Air mixed with steam is applied to the wood in a closed chamber, being alternately applied under pressure and suddenly blown off, followed with similar treatment of the wood by hot air alone.

Wall-coating composition. M. B. CHURCH. U. S., 1,166,325, Dec. 28. Un-calcined pulverized gypsum is mixed with about 1.5 times its wt. of whiting or other inert powder and about 10% its wt. of glue to form a H_2O -miscible compn. for coating walls.

Asphalt-fiber mixture for making roofing sheets. J. C. WOODLEY. U. S., 1,166,166, Dec. 28. Paper is dipped into molten asphalt, surplus asphalt is drained off and the paper coated with asphalt after cooling to a gummy or pasty mass is forced through perforated plates or otherwise thoroughly disintegrated to distribute the fibrous material

uniformly throughout the mass. The product is then formed into sheets by rollers. Cf. C. A. 9, 3347.

Roofing mixture. O. MATTER. U. S., 1,167,195, Jan. 4. Fibrous material such as paper or felt is H_2O -proofed with tar or asphalt and rendered fire-proof with Ph_2PO_4 .

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Selecting and buying fuel. W. H. GRADY. *Proc. Am. Wood Preservers' Assoc.* 1916 (advance copy).—G. describes factors to be considered and methods for comparing the suitability and economy of different kinds of fuel for boiler heating. G. M. H.

Flameless surface combustion. J. POKORNY. *Oesterr.-ung. Z. Zuckerind.* 44, 114-39(1915).—A historical and theoretical résumé of surface combustion, including the results of some expts. with the Schnabel-Bone boiler. P. concludes that this type of boiler as compared with the most modern installations of well-known types in recent years, appears to show no great advantages which would make its installation in sugar factories desirable at the present time.

E. A. TSCHUDY.

The coal and coke handling equipment of the gasworks of Budapest-Obuda. VIKTOR SCHÖN. *J. Gasbel.* 58, 461-8, 477-82, 496-505(1915).—A lecture, illustrated with 31 excellent photographs and drawings.

W. L. BADGER.

The spontaneous combustion of coal. R. NÜBLING AND HERTA WANNER. Stuttgart. *J. Gasbel.* 58, 515-8(1915).—An attempt was made to find the substance responsible for the spontaneous heating of coals. A Ruhr coal (A) and a Yorkshire coal (B), both subject to spontaneous combustion, and a Saar coal (C) which gave no trouble on storage, were used. By heating in a stream of O_2 and noting the temp. at which there was a sudden rise in temp. the "ignition temp." was detd. This was lower as larger samples were taken, so 20 g. was made the standard sample. Matter sol. in pyridine was detd. by shaking with the solvent in the cold, pptg. the dissolved material by adding ether to the soln., repeating this, and finally evapg. the pyridine in a vacuum at 80° , the last being driven off in a vacuum at room temps. After washing with ether and drying, the material pptd. by ether and obtained by evapg. the pyridine soln. was combined as "extract." The ignition point of a 20 g. sample (1), of a 20 g. sample after extn. (2), of 6-7 g. of ext. (3), and the % ext. obtained were: Coal A, (1) 152° , (2) 187° , (3) 146° , (4) 6.5%; coal B, (1) 138° , (2) 173° , (3) 146° , (4) 9.4%; coal C, (1) $165-182^\circ$, (2) 172° , (3) not detd., (4) 5.8%. The ignition temps. of mixts. of ext. and coal were detd.; in most cases they were between the ignition temps. of the constituents. Ultimate analyses showed a higher H content in the ext. than in the original coal, so Br absorptions were detd. Grams of Br taken up by 5 g. of untreated coal (1) or extd. coal (2) were: Coal A, (1) 0.7, (2) 1.9; coal B, (1) 0.6, (2) 1.3; coal C, (1) 1.0, (2) 2.6. The ext. in no case absorbed Br. W. L. BADGER.

Products and by-products of coal. E. S. STANSFIELD AND F. E. CARTER. *J. Gas Lighting* 132, 135-6(1915).—A discussion of a recent bulletin of the Canadian Dept. of mines, in which are described the present state and outlook for the future of the coal by-products industry in Canada.

F. L. GROVER.

Experiments on the removal of carbon disulfide from illuminating gas. HERTA WANNER. *J. Gasbel.* 58, 456-7(1915).—Gas was passed through coke from several sources, kieselguhr, coal (gas and boghead), sawdust, pitch, and charcoal. Gas coal and coke from lignite showed some absorption of CS_2 but not enough to be of importance; the other materials were without effect. A gas of 73.1 g. S per 100 cu. m. was passed

through 1 kg. of charcoal with a velocity of 0.13 cm./sec. From 5 to 6 cu. m. were purified below 20 g. S per 100 cu. m. (a figure considered satisfactory) and after 9 cu. m. had passed the S was 34 g. per 100 cu. m. Regenerating the charcoal gave a slightly lower activity, pulverizing it, a slightly higher effect. A test using 15.7 kg. in 2 layers showed that 1 kg. would purify about 10 cu. m. of gas below 20 g. S per 100 cu. m.

W. L. BADGER.

Gas purification by carbonate of potash. P. L. PETIT. *Gas World* 63, 374(1915); *J. Gas Lighting* 131, 645-6(1915).—The gas is passed through a rotary washer containing a solution of K_2CO_3 which removes H_2S and HCN as follows: $H_2S + K_2CO_3 = KSH + KHCO_3$. $HCN + K_2CO_3 = KCN + KHCO_3$. CO_2 is also absorbed up to a point of equil. between K_2CO_3 , $KHCO_3$ and CO_2 . This retards the absorption of H_2S , but not to the point of inefficiency. In fact the process is found much more efficient than iron oxide treatment. The soln. is easily regenerated by passing air through it. By warming the soln. and charging the ingoing air with 2 or 3% of CO_2 the regeneration is considerably accelerated.

R. H. SAWENS.

Gas from peat. G. A. BRENDER & BRANDIS. *J. Gas Lighting* 132, 94(1915).—Expts. were made upon two sorts of peat (heavy lumps and small lumps) in a horizontal retort. The gas contained CO_2 13, heavy hydrocarbons 2.1, CO 23.8, CH_4 12.1, H 39.6 and N 8.7%, and had gross calorific value of only 366 B. t. u. Roughly 17,500 cu. ft. of such gas were produced per metric ton of peat, and 0.402 ton of wet coke of poor quality. It was found that the most practical way of carbonizing peat was to mix it with 80-90% English gas coal. This increased the yield of gas from 10,000 cu. ft. per ton for 100% coal to 12,700 cu. ft. for 80% coal and 20% peat. The quality of the coke was fairly good in this case, and the calorific value of the gas was hardly affected.

F. L. GROVER.

Development in Doherty washer-cooler as gas-condenser at Detroit. R. B. ROWLEY. *J. Gas Lighting* 132, 141-2(1915); *Am. Gas Light J.* 103, 231, 234-6(1915).—A single-stage gas condensation has been substituted for a double stage at the Detroit City Gas Plant, which allows of condensation of the tar at a high temp. in a very short time. Simplification and added ease in manipulating by this change are claimed.

F. L. GROVER.

New system of retort-house control. ANON. *Gas World* 63, 495-6(1915).—The fundamental idea of the system is to make it possible to det. the quality of the gas immediately after it is produced, instead of being compelled to wait until the jet photometer at the exhauster gives some indication. Where the jet photometer is fitted after the exhauster there is a delay of 30 min. to 1 hr. between the time of actual gas making and actual test, by which time the conditions in the retort house may have altered to such an extent as to require modification in the opposite direction from that inferred from the jet photometer reading. With the new arrangement the value of the gas is known as soon as it is produced in the retort house and the "pull" increased or decreased "on the spot" as may be found necessary. A special means of efficient drawing gas from the foul main and delivering it to the testing app. under pressure has been devised. The instrument can be placed in the retort house. A drawing showing the max. and min. variations in illuminating power with and without the controller is shown; an outline sketch of controlling app. is given.

M. L. TROWBRIDGE.

Bradford road gas works of Manchester corporation. J. G. NEWBICING. *J. Gas Lighting* 132, 248-50(1915).—A description of some of the more important features connected with the new installation.

F. L. GROVER.

Glover-West verticals at Ottawa. ANON. *J. Gas Lighting* 132, 196(1915).—Description of recent installation of Glover-West retorts at the plant of the Ottawa Gas Company.

F. L. GROVER.

Care and maintenance of "DeBrouwer" retort charging and discharging plant.

H. C. WIDLAK. *J. Gas Lighting* 132, 480-2(1915).—The charging mechanism described in this article is dependent in principle upon the velocity of a horizontal belt which carries the coal, and projects it horizontally into the retort. From a hopper the coal is fed by gravity into a large groove cut in the face of a pulley covered by the belt. Thus enclosed the coal is carried around $\frac{1}{4}$ of a revolution of the pulley and out on the belt to the mouth of the retort into which it is projected. Detailed diagrams of electrical connections and safety devices are given. Various sizes of coal demand different "projector belt" speeds, and in filling a retort it is desirable to slow up as it fills from back to front.

R. H. SAWENS.

Sewage sludge for gas making. C. J. SNYDERS. *J. Gas Lighting* 132, 643(1915).

—City sewage was first settled in a tank and the water drawn off, leaving a sludge with less than 25% H_2O . This was distd. from a specially constructed oven giving 5966 cu. ft. of gas per ton with net calorific value of 454 B. t. u. The poor quality coke resulting was used only in the ovens for treatment of refuse. It was found that the heat of the chimney gases could be used to carbonize the sludge. The tar yields a high distg. oil suitable for engine oil.

R. H. SAWENS.

Increased toluene production. B. DUNGLINSON. *J. Gas Lighting* 132, 637-8

(1915).—A short discussion of methods now in use for the detn. of aromatic hydrocarbons in coal gas is given, and it is suggested that the detn. could be made to better advantage by washing the gas free from olefins and H_2O and passing over naphthalene with a paraffin catch bottle following. Ordinary methods for increasing toluene yields are of doubtful value. Passing steam through the coal charge promotes dissociation and different recombination of H and O. The principal effect however is the lowering of the distn. temp. and thus decreasing the "cracking" of aromatic hydrocarbons already formed. Referring to C_6H_6 , high yields are obtained by using low H_2O coal and a lower coking temp. This also increases the NH_3 yield.

R. H. SAWENS.

Benzole. GEORGE TAYLOR. *Colliery Guardian* 110, 1285-7(1915); *J. Gas Lighting* 132, 639-42(1915).—A detailed description of methods of extn., distn., and purification.

H. L. OLIN.

Iron carbonyl in water gas. LEONARD M. LIDDLE. *J. Ind. Eng. Chem.* 8, 89-90 (1916).—The presence of Fe in water gas kept in steel cylinders under 500 lbs. pressure was found to be due to the action of CO on the metal with the formation of $Fe(CO)_5$.

H. L. OLIN.

Tar dehydration. E. V. CHAMBERS. *J. Gas Lighting* 132, 261-4(1915).—The Roads Board Authorities issue specifications for temps. at which tar must be dehydrated for various purposes: for tar spraying 230°, for tar macadam 260° and for pitch grouting 288°. The distillate contains a larger % of light oil when the tar is dehydrated at a const. temp., and more phenol and cresol at a high temp. An app. is described for dehydrating tar continuously. The tar is heated in a layer not over 6 in. thick with 2.5 ft. vapor space above to prevent frothing over. Tar containing 40% water is easily dehydrated in this app. To prevent coking of the tar by overheating, the heat is evenly applied inside a horizontal tube submerged in the tar. The incoming tar is heated by the outgoing hot tar in a heat exchanger. A special coke breeze furnace is used as a source of heat. 67 lbs. coke breeze or 550 cu. ft. of 500 B. t. u. gas will dehydrate 1 ton of tar at 260°. On the av. 15 tons of light oil are obtained per 100 tons of tar, the light oil being condensed in a worm cooled by the incoming cold tar. F. L. G.

"Hird" tar-dehydration plant at Tottenham. R. WARDELL. *J. Gas Lighting* 132, 375-7(1915); *Gas World* 63, 487-9(1915).—The dehydration of tar for surfacing roads is accomplished by a continuous distn. process as follows: The crude tar is pumped

directly from the wells into pipes which serve as a condenser for the still vapors where it receives a certain amt. of heat before entering the heat "interchanger." In the "interchanger" it is warmed to about 160° F. by the outgoing tar and from there moves into the still. Here, passing through a series of channels formed by baffle plates, the vapors are given off, passing through the still head into the condenser, and thence by gravity through a sight box to the receiving tank. Any H₂S is trapped at the sight box and is carried to a small oxide purifier. Owing to the shallow layer of tar in the still and the ample vapor space above, it readily accommodates either coal-gas or carbureted water-gas tar. In a test on the latter, 1410 gals. were treated at a cost totaling, 14 d. per gal. It is estd. that coal-gas tar containing 5 to 10% water can be prep'd. at 1/10 to 1/8 d. per gal.

R. H. SAWENS.

Partial distillation of tar in Wilton's continuous still. F. LIVESKY. *J. Gas Lighting* 132, 373-5(1915); *Gas World* 63, 485-7(1915).—A description of the plant is given together with a drawing showing elevation and plan. Many important points in working are discussed, including the influence of temp., making of motor fuel, toluene, precautions in shutting down, repairs and financial results.

M. L. T.

By-product coking and chemistry. D. R. WATTLEWORTH. *J. Gas Lighting* 132-321(1915).—W. deplores the lack of chemical control in by-product coking in England.

F. L. GROVER.

Report of special committee on specifications for preservative for wood paving blocks 20. Coke for the iron blast furnace (KURADO) 9.

Dust separation in dressing fine coal. F. JÜNGST. *Ger.*, 285,456, May 6, 1914. The non-settling dust is sep'd. entirely by removing it, upwards, together with a part of the sedimentary material (up to 1.5 mm. diam.). This dust is then led, for further treatment, to the surface of a liquid, where the impurities sink, while the coal (up to about 1.5 mm. diam.) floats.

Fuel; pitch. A. C. EVANS and P. J. MITCHELL. *Brit.*, 19,933, Sept. 18, 1914. A pitchy binding-material, applicable for coal briquets and roads, is obtained from coal-tar or mineral oil residues by distg. off the light oils, adding coal dust or hydrocarbon soot (containing volatile matter), again heating until the added material softens and gives off vapors, cooling below 100°, and thickening by means of H₂SO₄, or less preferably SCl₂ or the like. Coal tar is distd. at 270° in a still provided with a stirrer; the residue is cooled just below 250° to prevent combustion, before the coal dust, etc., is added through a man-hole. The amt. added varies between 2.5 and 15% for briquetting or up to 30% for road-making. Reheating takes place up to 270° or over; cooling may occur in the still or in a sep. tank with a stirrer. H₂SO₄ of 170° Tw., amounting to between 0.25 and 1%, is added slowly so that the temp. may not rise over 100° or fall below 49°. The product softens and melts at about the same temp. as medium pitch and has a higher volatilization point by some 70°, but is free from phenols. Shale oil or the like is distd. until of the same consistency as tar distd. at 270°.

Composition fuel. H. FARADAY. *Brit.*, 19,495, Sept. 7, 1914. A mixt. of 5 or 6 parts of NaCl and 2 parts of maize is incorporated while dry with enough coal to make 100 parts, the product being steamed in an agitator and molded hot. Bituminous coal may be used, or 15 parts of it may be mixed with the balance of anthracite before incorporation with the binder.

Gas producer. W. B. CHAPMAN. U. S., 1,165,569, Dec. 28.

Gas producer. J. M. RUSBY. U. S., 1,165,715, Dec. 28.

Gas producers. W. R. DEGENHARDT. Brit., 19,652, Sept. 10, 1914. In a producer fitted with a steam and air supply at the base of the feed-hopper, as described in 22,618, 1913 (C. A. 9, 858), the hopper is provided with a container for sawdust and other fine fuel, which is removed bodily when it is desired to charge large logs of wood. The container is formed with a bell-mouth of wire-gauze or perforated metal, so that air, etc., can circulate through and gradually char the fresh fuel and so prevent packing. Cf. C. A. 9, 1108.

Gas producers. W. CLIMIE and W. LEES. Brit., 19,954, Sept. 19, 1914.

Gas producers. H. KOPPERS. Brit., 20,016, Sept. 21, 1914. See Ger., 279,550 (C. A. 9, 1387).

Apparatus for making and burning producer gas. O. B. EVANS. U. S., 1,165,657, Dec. 28.

Gas manufacture. M. DE JONGH and A. PACCHIONI. Brit., 20,276, Sept. 28, 1914. Between the ascension pipes and hydraulic main of a gas plant intermediate rising and falling pipes are inserted which are sepd. by partitions and jacketed for cooling.

Washing gases. W. B. DAVIDSON and A. J. LIVERSEDGE. Brit., 19,028, Aug. 25, 1914. In gas-washing app. of the type comprizing a number of superposed chambers each containing a rotary sprayer, and provided with gas passages round the sides or between the sides and the center, a grid of substantially vertical baffles is mounted in each chamber to guard the gas passages from the sprayed liquid. Cf. C. A. 9, 2707.

Coal gas. H. A. CARPENTER. U. S., 1,166,183, Dec. 28. Coal is placed in retorts with walls through which the gas generated may pass and the retorts are heated to a gas-making temp. while a lower pressure is maintained outside than inside the retorts to avoid leakage of combustion gases into the retorts from the heating chamber in which they are placed.

Cooling and cleansing coal gas. H. A. CARPENTER. U. S., 1,167,149-50, Jan. 4. App. and method are specified.

Separating water gas into its constituents. BADISCHE. Ger., 285,703, Feb. 18, 1913. Gas mixts. with a like high content of H respond to this treatment. The cooling action resulting from the expansion of the gas mixt. is utilized for the liquefaction of the constituents other than H. External cooling is not required if, instead of water-gas of normal production, a gas mixt. be used containing a higher content of CO or other gas with a positive Thomson-Joule effect. The normal gas may be enriched with CO or the gas may be manufd. in such manner that the product contains the desired amt. of CO. The procedure recommended is to add the liquefied CO to the water-gas either before or after the compression. The liquefied portion may be rectified, and that portion containing H may be returned to the process. The advantage in this is that only two gases, of high purity, leave the app.

Recovering cyanogen and ammonia from distillation gases. P. VON DER FORST. Ger., 280,652, Oct. 22, 1913. The NH_3 gas liberated in the distn. of the sepd. wash H_2O which contains NH_3 together with Cu compds., is conducted into the $(\text{CN})_2$ washer, arranged before the NH_3 saturator and charged with Cu compds., so that it is converted into the complex Cu-cyanogen compds., and is obtained in the subsequent treatment of these compds. with dil. acid as a soln. of $(\text{NH}_4)_2\text{SO}_4$, which is placed in the saturator for the purpose of crystallizing out the salt.

Apparatus for extracting oils, spirits and gases from peat or other organic material. A. N. MACNICOL. U. S., 1,165,889, Dec. 28.

Distilling coal. F. C. BLYTHE. Brit., 19,750, Sept. 14, 1914. In the destructive distn. of bituminous coal, heavy hydrocarbon oil, such as petroleum, kerosene, shale oil, and heavy tar oil, obtained in some cases during the process, is added to the coal, which is then distd. under pressure and at a comparatively low temp. regulated so as to produce a large proportion of hydrocarbon oils and a small proportion of permanent gas. In one method, about 5 to 10 parts of hydrocarbon oil are mixed with 100 parts of crushed or ground coal, and the mixt. is heated in a closed vessel, provided in some cases with an agitator, under a pressure of about 60 lbs. to the sq. in., and the temp. may be gradually raised to 350° and thence to about 500°. The heating may be by means of superheated steam with or without external heat.

Disinfectants. G. T. MORGAN and G. E. SCHARFF. Brit., 19,253, Aug. 31, 1914. Highly germicidal acidic substances sol. in aq. solns. of caustic alkalis are produced from peat tar by distg. the tar until the distillate solidifies to a waxy consistence at normal temp., extg. the distillate with excess of aq. caustic alkali, treating the ext. with mineral acid to liberate the acidic substances, and fractionally distg. these substances under the control of bactericidal tests. The fractionated liquids may be used singly or in various combinations in the manuf. of antiseptics, etc., and may be dild. with org. solvents, or mixed with H₂O, or emulsified by admixt. with gum acacia, mucilage, castor oil soap, etc. They may also be made up in solid form by mixing with hard soap, cane sugar, milk sugar, dextrin, starch, gums, resins, fullers' earth, infusorial earth, gypsum, powdered chalk or whiting, slaked lime, animal or wood charcoal, etc.

Automatically operated car for charging coke ovens. E. HUNGER. Ger., 285,353, May 7, 1914.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Presence of benzene homologs in the high boiling distillates of petroleum. BENJAMIN T. BROOKS AND IRWIN W. HUMPHREY. *J. Am. Chem. Soc.* 38, 393-400 (1916); cf. C. A. 8, 3360.—When a "reduced" Oklahoma oil (that part of the crude petroleum remaining after removing by distn. all that b. below 275°), d_4^{20} 0.877, is cracked by slowly distg. under 100 lbs. pressure, the temp. gradually rising during the distn. from 375° to 415°, and that portion of the distillate b. below 150° is extd. at -15° with liquid SO₂, the ext. yields 2.2 vol. % of the original charge and from this, on fractionation and nitration, are obtained *m*-C₆H₄(NO₂)₂, 2,4-(O₂N)₂C₆H₂Me and 1,3,2,4,6-C₆HMe₂(NO₂)₂. Similarly, 20 l. of reduced oil distd. with 6% anhydrous AlCl₃ yields 0.4 l. SO₂ ext. from which the above NO₂ compds. are obtained. Of natural gasolines distd. from various crude oils (Bristow, Muskogee, Mexican, California) 4.5-14% is sol. in SO₂, and of a Texas solar oil cracked with AlCl₃ 32.5%. Com. paraffin is more difficult to crack than light lubricating oil composed almost exclusively of naphthenes and polynaphthenes; in parallel expts. under 100 lbs. with reduced Jennings oil and paraffin, the temp. at 1 hr. intervals, beginning 10 min. after distn. commenced, was found to be 370°, 415°, 422°, in the case of the oil, and 417°, 432°, 437° in that of the paraffin. Similar results are obtained with AlCl₃; below are given, resp., the temp. when distn. begins and at the end of 4 hrs. and the yield of product b. below 150°: Jennings reduced oil, 200°, 355°, 22.2%; Texas solar oil, 175°, 210°, 24.5%; paraffin, 205°, 282°, 4.5%; phenylparaffin, 185°, 265°, 15.0%. A mixt. of phenylparaffins, prepared by treating 2 kg. melted paraffin with Cl until it gained 251 g. in wt., then treating with C₆H₆ and AlCl₃ in CS₂, when heated 3 hrs. with 7% AlCl₃ at 200-40°, yielded C₆H₆ and PhMe (55 and 11 cc., resp., from 500 g. phenylparaffin).

The formation of PhMe can be accounted for only by the splitting of the phenylparaffin into $\text{PhCH}_3 + \text{CH}_3\text{R}$. In this reaction the higher boiling portion of the material is converted into a mixt. of naphthenes: After pouring off the warm residue from the AlCl_3 and pitch and chilling the oil, 32 g. cryst. paraffin sepd.; the filtrate from this resembled light lubricating oil but possessed an intense green fluorescence, resembling very much the oil obtained by treating Mexican crude petroleum with a little AlCl_3 . From 2.5 kg. of the above phenylparaffin distd. 3 hrs. under 75 lbs. were obtained 112, 150 and 272 cc. b. $70-100^\circ$, $100-15^\circ$ and $115-45^\circ$, resp., the first 2 fractions yielding 25 and 41 g. $\text{C}_6\text{H}_4(\text{NO}_2)_2$ and $(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Me}$, resp. The residue from the distn. of pure paraffin was not fluorescent.

CHAS. A. ROUILLER.

Equilibrium relations among aromatic hydrocarbons produced by cracking petroleum. W. F. RITTMAN AND T. J. TWOMEY. *J. Ind. Eng. Chem.* 8, 20-2 (1916).—The authors have studied these relations by cracking a Penn. fuel oil, d. 0.83, b. p. $300-400^\circ$. The cracking was done in a furnace consisting of a tube 10 ft. long and 8 in. in diam. and having a capacity of 15-20 gals. of oil per hr. Expts. were made at 200-250 lbs. per sq. in. pressure and at temps. varying from 550 to 700° . The resulting oils were analyzed for aromatic hydrocarbons. They conclude that there are definite relations between the % of aromatic compds. formed, the percentages being fixed by the degree of cracking. Toluene and xylene show the same variation in amt. formed, about $1/2$ as much xylene being formed as toluene. Benzene formation requires more strenuous cracking. Its max. formation is at a point at which the % of toluene and xylene have fallen off considerably. Naphthalene begins to form about where the toluene-xylene content possess its max., indicating that it is formed by the decompn. of monocyclic hydrocarbons. Anthracene behaves similarly to naphthalene and its formation requires still more strenuous conditions. Curves are given showing the relation between the % of the different aromatic hydrocarbons and the d. of the cracked oil.

F. M. ROGERS.

Thermal reactions of aromatic hydrocarbons in the vapor phase. W. F. RITTMAN, O. BYRON AND G. EGLOFF. *J. Ind. Eng. Chem.* 7, 1019-24 (1915).—The purpose of this investigation is to establish facts concerning the influence of temp. and pressure on inter-aromatic reactions. Cymene, xylene, toluene, and benzene were subjected to cracking, each at 3 different temps., and at each temp. under 4 different pressures. The app. consisted of an electrically heated furnace fitted at one end with an oil feed cup and a vaporizer, and at the other end with a condenser, receivers for the liquid reaction products, and a pressure-regulating device. The operation consisted in first connecting the system with a compressor and a natural gas supply until the proper pressure was obtained, after which the product to be cracked was introduced into the electrically heated furnace. The temps. used were 650° , 725° and 800° ; the pressures, 1 atm., 12 atms., 18 atms., and vacuum. The vol. per cent. of oil recovered, the % wt. of carbon, the sp. gr. and distn. of the reaction products were detd. From $\text{C}_{10}\text{H}_{14}$ it was found possible to obtain C_8H_{10} , C_7H_8 , C_6H_6 , C_{10}H_8 and anthracene. From C_8H_{10} , there were produced C_7H_8 , C_6H_6 , C_{10}H_8 and $\text{C}_{14}\text{H}_{10}$, but no $\text{C}_{10}\text{H}_{14}$. C_7H_8 yielded all of the above hydrocarbons except $\text{C}_{10}\text{H}_{14}$ and C_8H_{10} . C_6H_6 gave only C_{10}H_8 and $\text{C}_{14}\text{H}_{10}$. C_{10}H_8 yielded $\text{C}_{14}\text{H}_{10}$, but none of the monocyclic hydrocarbons. $\text{C}_{14}\text{H}_{10}$ produced only some tarry matter, carbon and gas.

O. E. BRANSKY.

Gasoline from heavier hydrocarbons. C. ELLIS AND A. A. WELLS. *J. Ind. Eng. Chem.* 7, 1029-33 (1915).—The purpose of this work was to det. the commercial feasibility of several methods of gasoline production. Still cracking under normal and atm. pressure, tube cracking, heating with reagents, and contact with molten metal were studied. Tube cracking was studied in a semi-commercial app. of 1000 gals. capacity, consisting of a still, a tubular decomposer, and a condenser. A 6 in. vapor

line connected the still with the decomposer, which consisted of 6 sections of 3 in. pipe, each section 75 ft. in length. The coils were surrounded by a furnace setting of bricks, and supported by iron pipe supports, through which water was circulated to prevent bending by heating. The condenser consisted of 1000 ft. of 2 in. pipe. Illinois crude, gravity 33° Bé., test distillate, gr. 42.5° Bé., gas oil, gr. 34°, and fuel oil, gr. 21 to 22°, were used in the expts. The vapors from the still were passed into the decomposer, where the cracking occurred, and the resulting vapors condensed in the condensing coils. At a temp. from 450° to 600° yields of gasoline varied from 18 to 28%; by re-running the residues from the distn. of the cracked products, yields as high as 26% were obtained. The loss as fixed gas and entrained vapor were const. at 16 to 18%. The I no. of the cracked gasolines ranged from 50 to 310, the lower boiling fractions giving the higher I values. On long standing the cracked products became darker, and a heavy residue was left on redistn. Hydrogenation improved the color, odor, and stability of the cracked oils. The olefin content of the fixed gases approached 40% in several cases, and was readily chlorinated.

O. E. BRANSKY.

Coal-tar colors, and the Hall process of manufacturing gasoline from "gas oil." C. F. CHANDLER. *J. Ind. Eng. Chem.* 8, 72-5(1916).—A lecture forming part of a symposium on the dyestuff situation.

F. M. ROGERS.

Examination of steam turbine oils. F. SCHWARZ AND J. MARCUSSEN. *Mit. kgl. Materialprüfungsamt.* 32, 496-502(1914); *J. Soc. Chem. Ind.* 34, 1235(1915).—For detg. the tar-forming value of mineral oils, S. and M. prefer to heat at 120° instead of 150° as recommended by Kissling (*C. A.* 1, 1770; 3, 712, 954). The subsequent treatment is then facilitated, as practically no coke is formed; and the tar-forming values thus detd. are just as valuable as the sum of the tar-forming and coke-forming values (Kissling) for characterizing turbine oils. Heat 50 g. of the oil in a 200 cc. Erlenmeyer flask (diam. of bulb 7.5 cm., height 12.5 cm.) for 50 hrs. continuously in an air-oven at 120°. The flask stands inside a shallow, thick-walled porcelain vessel which rests on a thick sheet of asbestos a few cm. above the bottom of the oven, the inner wall of the oven being preferably lined with asbestos. Treat the oil with 50 cc. of an aq. soln. containing 50% of alc. by wt. and 4% of NaOH, heat for 15 min. at 80° under a reflux condenser, shake vigorously for 5 min., and transfer to a sepg. funnel. Let stand overnight, filter, ext. with 30 cc. of light petroleum spirit, acidify with dil. HCl, and remove the tarry substances by extg. several times with C₆H₆. Wash the C₆H₆ soln. with H₂O evap., and dry the residue at 105° for 10 min. The portion of mineral lubricating oils sol. in acetone (*C. A.* 6, 3011), has a higher tar-forming value than the original oil, and if the acetone-sol. portion be dissolved in petroleum spirit and shaken with castor oil, the latter exts. a portion with a still higher tar-forming value. It is obtained in the form of a soft resinous mass, which can be sepd. by treatment with fullers' earth and extn. with petroleum spirit into about 15% of a solid resin and 85% of a viscous oil. Cf. *C. A.* 7, 3019.

F. W. SMITHER.

Note on ductility test of asphalt. T. LINSKY CROSSLEY. *J. Ind. Eng. Chem.* 8, 89(1916).—To differentiate between asphalts having a ductility of over 100 cm., the

usual length of a ductility machine, the author pulls the briquet apart at the rate of 10 cm. per min. instead of 5. The fast pull is a more severe test. F. M. ROGERS.

Effect of controllable variables upon the penetration test for asphalts and asphalt cements. PRÉVOST HUBBARD AND F. P. PRITCHARD. Office of Public Roads and Rural Engineering. *J. Agr. Research* 5, 805-18(1916).—The object of this investigation was to det. what effect apparently slight differences in temp., load and time produce in the results of tests and also to study the importance of other controllable variables. Melted samples should be cooled for not less than 2 hrs. prior to test, and should be tested upon the same day that they are melted, preferably after 2 or 3 hrs. Samples should be maintained at the testing temp. for not less than 1 hr., and preferably for $1\frac{1}{2}$ hrs. prior to test. Upon standing in the air, prepared samples show a decreasing penetration, but no definite end point or set is produced up to 28 days. In ordinary lab. work there is no apparent advantage in cooling samples in ice or ice water prior to detg. their penetration at higher temps. Cooling in ice water is, therefore, not recommended. Samples should be maintained and tested within 0.1° of the desired temp. for accurate work, as a variation in temp. of less than 0.5° may produce a decided difference in results. Tests at 4° are not the practical equiv. of properly made tests at 0° . When making tests at 0° samples should not be packed in crushed ice, but should be immersed in a brine bath. The increase in penetration of a material detd. under given conditions of temp. and time is, within certain limits, almost proportional to the increase in load. For the 100- and 200-g. loads variations of as much as 1 g. do not as a rule seriously affect detns. It is, however, recommended that in all cases the load should not vary more than 0.2 g. from that desired. In any test, proportionally the greatest number of points penetration is obtained during the first sec. In the 5-sec. tests approx. $\frac{1}{2}$ the total penetration is obtained during the first sec. A variation of $\frac{1}{2}$ sec. may, however, produce an appreciable variation in results. A carefully calibrated metronome is recommended for securing the proper time control. Aside from possible variations in needles, it is believed that variations in results obtained upon the same material by different labs. are more probably due to unobserved variations in the methods of prepg. the sample and to the control of temp. than to any other cause. It is believed that a study of the penetration of various types and grades of bituminous materials under a variety of conditions of temp., load, and time may throw considerable light upon their other physical and chem. characteristics, and may serve as a possible means of identifying their origin and method of manuf. W. H. FRY.

Evaporation tests with wood refuse. H. WINKELMANN. *Papier Fabr.* 13, 680-1, 694-8(1915).—Records of several boiler tests using wood waste as fuel. V. N.

Origin of petroleum and asphalt (RICHARDSON) 8. Lubricating-oil testing machine (SLAUGHTER) 1.

Distilling tar, oil, pitch and other frothing liquids. K. I. CROSSLEY and H. W. BRIGHTEN. *Brit.*, 19,392, Sept. 3, 1914. In the app. for this purpose the fluid issuing from the still is allowed to expand through a restricted passage into a chamber in which the unevapo. liquid is deposited. The invention consists in (1) controlling the restricted passage by means of an adjustable valve, which is set, prior to the distn., by a hand-wheel and locked in position, (2) fitting the valve with a pointer and a graduated scale, (3) lagging the upper part of the still, the neck, and the expansion chamber, (4) fitting a safety-valve on the expansion chamber, the valve being set to lift at a very low pressure. The expansion chamber is fitted with a vapor-outlet pipe and with pipes for returning unevapo. liquid to the still.

Distilling oils. R. NEUMANN. Brit., 20,353, Sept. 30, 1914. Petroleum, tar, etc., comprizes a condenser in which a vacuum is maintained. The device is fitted with a device for discharging distillates at regular intervals. The device consists of a chamber which is placed alternately under vacuum and pressure. While under vacuum, the chamber receives distillate through an inlet valve. When under pressure, the chamber discharges through an outlet valve and a reversed siphon.

Apparatus for refining petroleum by distillation. R. G. JONES. U. S. Pat. 1,165,877, Dec. 28.

Refining petroleum. S. W. WHITMORE. Brit., 19,884, Sept. 19, 1914. Naphthalene is added to crude petroleum prior to distillation, or is added to the distillates or residues of distillation, to improve the color and odor, and the illuminating properties of the distillates and the lubricating properties of the distillates and residues.

Refining petroleum. H. HENNEBUTTE. U. S., 1,165,877, Dec. 28. Oil is prepared from mazout containing a large % of unsaturated hydrocarbon by passing a current of air through the material at a temperature of 100-350° and distilling with refining.

Distilling heavy saturated hydrocarbons. H. HENNEBUTTE. U. S. Pat. 1,165,877, Dec. 28. Heavy hydrocarbon oils such as petroleum or coal tar are heated to a temperature above their boiling points. Hydrocarbons such as petroleum distillate boiling at 170° are introduced in liquid form into the heated heavy oil while the temperature of the latter is above the boiling point of the lighter hydrocarbon so that the latter is immediately vaporized and serves as a carrier for the heavier hydrocarbon.

Apparatus for cracking petroleum. C. J. GREENSTREET. U. S. Pat. 1,165,877, Jan. 4.

Apparatus for making gas from crude oil. F. M. RITES. U. S. Pat. 1,165,877, Jan. 4.

Gasoline substitute for use in internal combustion engines. W. L. RAY. U. S., 1,165,462, Dec. 28. Crude petroleum 1 gal. is mixed with gasoline 2 oz., pulverized alum 2 dram and oil of citronella 1 dram.

Lubricating oils. J. ROSEN. U. S., 1,165,909, Dec. 28. Cylinder lubricating products are prepared by heating petroleum residue to about 320° and introducing the heated material, solar or cracked oil at a lower temperature so that it is immediately vaporized and acts as a carrier to facilitate the distillation.

Oil burner. J. HOWALDT. Ger., 285,434, June 22, 1913.

Tabular review of nitrocellulose substitutes in the manufacture of paper. SCHALL. *Kunststoffe* 5, 287-8 (1915); cf. *C. A.* 9, 3129.—Patents.

Sizing and coloring paper. E. FUES. Brit., 19,816, Sept. 15, 1914. Paper of 13,970, 1914, is now applied to paper and other absorbent material having different absorptive capacities at different parts of its surface. In so far as it relates to coloring paper of other kinds, and other absorbent material, it is also applied for coloring paper of other kinds, and other absorbent material simultaneously sizing.

Paper pulp. R. A. MARR. U. S., 1,166,848, Jan. 4. Oak, hemlock or other wood is digested with a soln. containing ZnSO_4 2-4, ZnCl_2 1-2, tannic acid 1-2 and glycerol 1-2%, under 50-150 lbs. pressure per sq. in.

Obtaining fiber and by-products from cotton stalks, cane, etc. M. W. MARSDEN. U. S., 1,165,689, Dec. 28. Short lengths of cane, straw or cotton stalks are satd. with H_2O , shredded, digested with H_2O under 10-40 lbs. steam pressure per sq. in. to saccharify the starch and invertible carbohydrates and after the resulting liquor is drawn off the fibrous residue is agitated and scoured with steam and converted into paper pulp. Cf. C. A. 9, 2311.

Recovering alkali from wood-pulp black liquor. A. B. AYERST and C. N. WAITE. U. S., 1,166,509, Jan. 4. The liquor is evapd. to thicken it, mixed with granular charcoal, the mixt. calcined while it is agitated to keep the constituents commingled and the calcined product is leached to remove the alkali. The residual charcoal is dried and used for treating another portion of the liquor.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

An apparatus for the study of gases and vapors liberated by explosives at ordinary temperatures. D. CHIARAVIGLIO AND O. M. CORBINO. *Rend. accad. Lincei* 24, 120-6(1915); through *Ann. chim. applicata* 4, 289.—With this app., which gives a very attenuated vacuum, expts. were conducted on the progressive liberation of occluded gases by pulverulent bodies, like P_2O_5 , and of explosive substances, like fulminating cotton. In the case of the latter, there was detected a slow decompn. at the ordinary temp. as the app. permitted an accurate measurement of the gas continually set free. S. LEVY.

"Adobe" as a material for the construction of explosives buildings. A. F. SAVINON. *J. Soc. Chem. Ind.* 34, 1039-40(1915).—Adobe, consisting of a mixt. of clayey earth, H_2O and straw, the latter being replaceable by manure or grass is recommended as a building material on account of the fact that it is a good heat insulator and also that buildings made of it are easily pulverized in case of an explosion. In discussion it was stated that such buildings should be coated with a cement wash or better a coat of blood and lime in order to stand the weather and further that buildings made of saw-dust concrete or a 1-10 cement sand mortar would be more serviceable.

A. J. PHILLIPS.

Military explosives. OTTO MYRIN. *Svensk Kem. Tid.* 27, 118-27, 149-57 (1915).—Résumé and discussion. A. R. ROSE.

Investigation of a hostile aerial incendiary bomb. A. WELLENSTEIN. Trier. *Chem. Zig.* 40, 9-10(1916).—The bomb was charged with yellow P surrounded by a non-inflammable, molasses-like fluid. J. H. MOORE.

Explosions-in-Mines Committee. VII. Effects of inhaling dusts applicable for stone dusting in mines. J. S. HALDANE. *Colliery Guardian* 110, 1181-4(1915). Experiments on the inhalation of different varieties of dust. A. MAVROGORDATO. *Ibid* 110, 1184.—The use of stone dust in mines for preventing coal dust explosions (cf. C. A. 9, 1393) raises the question of its physiological effects when inhaled. The breathing of dust in moderate quantity is not necessarily deleterious; expts. on guinea pigs show that powdered clay, shale, chalk, or other soft inert materials are harmless. Flue dust consisting largely of fused silicates, crushed granite, flint, ganister and similar

gritty media are dangerous, giving rise to chronic inflammation of the lungs. Any shale used for dusting should be free from them.

Liquid explosive. O. REUTER. U. S., 1,166,546, Jan. 4. Toluene is nitrated beyond the dinitrotoluene stage to form mainly trinitrotoluene, the liquid is separated out from alc., the alc. is evapd. from the mother liquor and the residue is further nitrated at 85–100° by the action of 15% HNO_3 and 85% H_2SO_4 , the product solidifying at 14° and containing 16.6–17.2% N.

Explosives. H. H. STOCKFELD. Brit., 19,267, Aug. 31, 1914. The explosive consists of a mixt. of nitroglycerin, nitrocellulose, nitrated Australian grass-tree gum, Ca picrate, KNO_3 , wood meal, and castor oil. The Australian grass-tree gum is nitrated by dropping fuming HNO_3 onto the gum in a bath of a mixt. of turpentine, and petroleum, then decanting and draining. The nitrated Australian grass-tree gum are purified by washing with an alk. soln. containing 96 parts of H_2O , 2 of borax, 1 of sugar, and 1 of lime; and the gum is further purified by boiling in a similar alk. soln., and then washing for about 24 hours with running H_2O .

Explosives. SOC. ITALIANA PRODOTTI ESPLODENTI and F. QUARANTA. 19,565, Sept. 9, 1914. Molding fusible explosive charges for projectiles in a mold with molten explosive, shaking or agitating it until solidification, and then adding at this moment a head of molten explosive, and maintaining this condition until solidification of the whole original charge, no pressure being applied, the wt. of the added charge being used. This process is carried out by means of an app. comprizing a mold for the pasteboard case to be filled, a steam-jacket for the molten explosive, and a valve. The mold is closed at the bottom and held in the closed position by a screw.

Explosives. SOC. ITALIANA PRODOTTI ESPLODENTI and F. QUARANTA. 19,566, Sept. 9, 1914. In the manuf. of trinitrotoluene, crude solid dinitrotoluene is subjected to a partial liquefaction to sep. the liquid and solid intermediate products. The solid product is nitrated, and the nitration mass slowly filtered to give trinitrotoluene, which is filtered, washed with H_2O , melted *in vacuo* to drive off the water, granulated, and dried. The liquid product is nitrated to give dinitrotoluene, which is treated as described above.

Ammunition; explosives. F. QUARTIERI and E. MOLINARI. Brit., 19,268, Aug. 31, 1914. High explosive charges are provided with a cushion in front of the main charge to absorb the stress of impact, this cushion being made of high explosive rendered insensitive to shock.

As shown, the main charge of high explosive is contained in a cardboard casing, *b*, and is sep'd. by a layer of high explosive rendered insensitive to shock, *c*, from the cushion *d* of high explosive rendered insensitive to shock, *e*. High explosive rendered insensitive to shocks, as follows: (1) by an addition of 2 to 20% of camphor, paraffin, or ceresin; (2) by an addition of 1 to 10% of camphor, paraffin, or ceresin to dinitrotoluenes, nitrobenzenes, and their homologs by nitration; (3) by gelatinization, by treatment with an alk. soln. of nitrobenzene, by treatment with a 30–35% soln. of NH_3 in H_2O . In some cases, insensibility may be increased by the addition of 1–12% of resin or India rubber.

Ammunition. W. H. BUELL. Brit., 20,307, Sept. 9, 1914. Bullets producing a flash of light on impact with a target, point hit, are charged with a compn. containing A

Several compns. are described: 1 example contains 40% Al, 30% KClO_3 , 20% trinitro toluene, 6% $\text{Sr}(\text{NO}_3)_2$, and 4% glass.

Molding explosives. SOC. ITALIANA PRODOTTI ESPLODENTI and F. QUARTIERI. Brit., 19,645, Sept. 10, 1914. In hydraulic reciprocating mold table machines for molding explosives, means are provided for ensuring the registration of the molds with the compressing piston and ejectors.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Dianisidine blue. JOSEF POKORNY. *Chem. Ztg.* 40, 10(1916).—The Cu salt of dianisidine- β -naphthol is violet if formed in the absence of a fatty acid, but in the presence of the latter different shades of blue are formed on cotton goods. It is probably a triple lake of dianisidine-diazo- β -naphthol with Cu and a fatty acid. J. H. M.

Aniline oxidation black on hosiery. ERNEST C. T. BICK. *Text. World J.* 4, 33-5.—Directions are given for dyeing with aniline black as a substitute for sulfur black or developed black, the steps in the process being (1) impregnation with aniline-HCl in the presence of an oxidizing agent, an O carrier and NH_4Cl ; (2) extn. of the surplus liquid by means of a "whizzer;" (3) oxidation of the dyed goods first in revolving drums and finally with dichromate, the latter being carried out at a temp. between 55 and 80°. The lising process is described and various formulas are given. L. W. R.

Tin phosphate weighting of silk. II. HERM. LEY. Elberfeld. *Chem. Ztg.* 39, 973-5, 986-7(1915); cf. C. A. 7, 895.—L. tabulates part of the tests on wash H_2O after the Sn and phosphate baths and of the alk. bath in a series of factory runs. The degree of acidity and alkalinity and the Cl tests are recorded. He concludes that only the washing after the Sn bath is of importance chemically, part of it serving to remove the excess of mechanically adhering SnCl_4 and part to decompose the absorbed salt into insol. $\text{Sn}(\text{OH})_4$. Washing after phosphating has no chem. influence on weighting, contrary to his former belief, but simply serves to remove the excess of Na phosphate. Insufficient washing results in the most varied changes in weighting, as, for example, the SnCl_4 may not be sufficiently decomposed or the NaCl not properly removed after phosphating. Thorough removal of the decompn. products by centrifuging after each step is of even greater importance than washing, and to the neglect of this may be attributed many of the dyer's troubles. No evidence was found of the formation of NaOH, as required by Heermann's theory of weighting. J. H. MOORE.

Dyes; dyeing. FARBW. v. M. L. & B. Brit., 19,272, Aug. 31, 1914. Stable sol. leuco preps. of the vat dyes obtained by condensing benzoquinone, α -naphthoquinone, or their homologs or substitution products, with aromatic amines, or the sulfurized derivs. thereof described in 19,599, 1912 (C. A. 8, 429), are prepd. by adding to the alkali salts of the leuco compds. of such dyes, during or after formation, soaps, e. g., monopole soap or turcone oil, or glycerol. The solns. obtained may be used directly for dyeing, either alone or mixed with solns. of reduced indigo or other vat dyes. According to examples: a vat soln. is obtained by heating di-*p*-chloroanilidobenzoquinone with NaOH lye, hyposulfite, and turcone oil; the same dye is reduced to its leuco compd. by means of hyposulfite and NaOH lye, the product is acidified, and the filtered-off leuco compd. is mixed with turcone oil, and NaOH lye; the dye obtained by treating dianilinodichlorobenzoquinone with Na_2S in alc. is heated with monopole soap, hyposulfite, and NaOH lye to give a vat soln.

Dyeing. E. LODGE and J. M. EVANS. Brit., 19,473, Sept. 5, 1914. In substantive dye processes, animal fibers, fur, feathers, union goods, and artificial silks are dyed with S dyes in alkali sulfide baths with addition of Na or K sulfite and a neutral NH_4 salt, such as the chloride, sulfate, or acetate. Examples are given of dye-baths containing cross dye black BX, thionol blue RB, and katigen blue black R.

Dyes; catalytic processes. A. BROCHET. Brit., 19,848, Sept. 16, 1914. Leuco compds. of vat dyes are obtained by treating the dyes with H in the presence of a catalyst, such as Ni; the process may be effected by suspending the dye in H_2O with the addition of an alkali and the catalyst, and introducing H or a gas containing H while violently agitating the mixt.; inorganic salts, such as chlorides or sulfites, may be added, and the reaction mixt. may be heated or the process conducted under pressure. An example is given of the production of indigo-white; algol, ciba, helindrone, hydrone, and indanthrene dyes are also specified as suitable.

Yellow disazo dye. H. GELDERMANN and F. HAAS. U. S., 1,166,346, Dec. 28. A yellow dye easily sol. in warm H_2O is made by combining 2 mol. proportions of diazotized 2-aminosulfodiphenyl ether with 1 mol. proportion of dipyrazolone derived from 4,4'-dihydrazino-3,3'-dimethyldiphenylmethane and Et acetoacetate. Similar dyes, dyeing wool yellow fast to washing, are obtained by using other dipyrazolones, *e. g.*, those produced from toluidine, 4,4'-diamino-3,3'-dichlorodiphenylmethane, 4,4'-diamino-2,5,2',5'-tetramethyldiphenylmethane or 4,4'-diamino-3,3'-dimethylbenzophenone.

Brown sulfur dyes. C. MÜLLER and W. STÖBER. U. S., 1,165,531, Dec. 28. 2,7-Dimethyl-3,6-diaminoacridine is heated with S and Na_2S and air is blown through an aq. soln. of the product to ppt. it. The resultant dye is insol. in H_2O and ordinary org. solvents, but gives a brown soln. with hot H_2SO_4 or hot Na_2S soln. and a reddish brown soln. with hot NaOH soln. and dyes cotton fast brown from the Na_2S soln. 2,7-Dimethyl-3,6-dihydroxy-9-phenylacridine or 2,7-dimethyl-3,6-diamino-9-hydroxy-phenylacridine or other methylaminoacridines give similar dyes.

Vat dyes of the benzanthrone series. BADISCHE. Ger., 284,700, Dec. 28, 1913. Addition to 267,418 (C. A. 8, 1016). These products are obtained either by employing halogen-substitution products in carrying out the parent process, or by subsequently halogenizing the prepared dyes free from halogen or already containing halogen. The products are in general clearer and in part materially redder in shade. Cf. C. A. 9, 2455.

Metal leuco compounds of the vat dyes. R. WEDEKIND & CO. Ger., 284,888, Dec. 21, 1912. Addition to 270,520 (C. A. 8, 3242). The parent process is extended to apply the treatment of alkali leuco compds. of vat dyes (excepting indigo) to other metal salts, as well as Mg salts. The products serve as initial materials in the manuf. of other dyes, as well as in dyeing and printing.

Aniline black. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 285,955, Dec. 13, 1913. A product which does not turn green is obtained by oxidizing, to blackness, the textile material impregnated with the chlorates of aniline and its homologs, at a temp. higher than usual, *e. g.*, 90-100°.

Dye lakes. BAYER & CO. Ger., 285,614, Aug. 1, 1913. Addition to 281,422 (C. A. 9, 2153). The sulfonic acids of quinizarin (1,4-dihydroxyanthraquinone) yield alumina lakes of much bluer shades than the purpurinsulfonic acids; the lakes have great clearness and fastness. *E. g.*, Na quinizarin- β -sulfonate 5 is dissolved in 10 to 15 times its amt. of hot H_2O , boiled with 1000 parts of $\text{Al}_2(\text{SO}_4)_3$ soln. 1:10, and then the alumina lake is pptd. with 400 parts of calcined soda soln. 1:10, filtered, washed,

and dried. For the production of blanc fixe for calcimining, 1000 parts of BaCl_2 soln. of 1:10 are added to the above.

Dry leuco compounds of dyes. BADISCHE. Ger., 285,322, Jan. 17, 1914. Herebefore the leuco compds. of dyes have been dried by evapn. in an indifferent gas current or *in vacuo*. A preferred procedure is to atomize the solns. or pastes of the leuco compds., with which other substances may be mixed (e. g., molasses), to a fine mist, and then to direct this counter to a current of hot air.

Sulfur-containing derivatives of aromatic amino compounds. KALLE & Co., AKT.-GES. Ger., 285,501, Dec. 31, 1913. Two mols. of a sulfinic acid of the aromatic series are allowed to act on 1 mol. of a *p*-hydroxy- or an amino-azo dye, whereby the reaction proceeds more smoothly.

Indigoid vat dyes. BAYER & Co. Ger., 285,864, Dec. 7, 1913. If the reactive α -derivs. of halogen-substituted isatins or naphthisatins are condensed with 3-Ph-1-indanon as well as its substitution products, homologs or analogs, intensely colored indigoid vat dyes are obtained.

Derivatives of indirubin. FARBW. v. M. L. & B. Ger., 284,317, Oct. 23, 1913. Addition to 283,726 (C. A. 9, 3368). Indirubin derivs. are obtained by the parent process when hydroxylamine is allowed to act upon indirubin. Instead of indirubin itself, its leuco compds. may be brought into reaction, in alk. soln., with hydroxylamine. The end products are the same as those of the principal patent.

Apparatus for dyeing. W. INMAN. U. S., 1,166,989, Jan. 4.

Dyeing machine. K. CALLEBAUT and J. DE BLICQUY. Brit., 19,062, Aug. 25, 1914. In a dyeing machine comprizing a removable cage or receptacle for the material, the receptacle is arranged to hold the material in a single horizontal layer above or below the usual liquor inlet chamber, or in one layer above and one below. The walls of the receptacle are preferably conical or inclined, the inlet chamber being at the base or between the bases of the cones.

Textile conditioning and storage apparatus. I. E. PALMER. Brit., 19,201, Aug. 28, 1914. The progress of the material through a storage receptacle, in which treatment of various kinds may or may not be carried on, is controlled by the material itself. The app. is adapted to receive material in rope or chain form, or in the condition of flat goods of suitable width, such material being treated in the app. or previous to its entrance thereto, with any suitable conditioning liquor, such as a bleaching, dyeing, or finishing liquor. The storage receptacle or shoot is fitted with a positively operated conveyer, which is automatically controlled by the material itself to facilitate the passage of the material through the receptacle in such a way as to prevent tangling, the material being arranged in folds preferably extending across the shoot and normal to the walls thereof.

Waterproofing rope. R. A. MARR. U. S., 1,166,847, Jan. 4. Rope is immersed in a bath of C_{10}H_8 and paraffin at a temp. of $115\text{--}125^\circ$ and allowed to remain in the mixt. until its temp. has fallen somewhat. Cf. C. A. 9, 382.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Coumarone resins. M. BOTTLER. *Kunststoffe* 5, 277-80(1915).—A review and discussion of the patented processes for the production of artificial resins as polymerization products from cumene and indene. (Generally by the action of H_2SO_4 on crude

benzene.) B. describes some of these products and tests made on them. The use of these materials in the varnish and lacquer industry will be discussed in a later paper.

F. W. SMYTH.

Pigment. L. BLANGEY. U. S., 1,166,808, Jan. 4. "3,3'-Dinitro-4,4'-diamino-sulfobenzid" is combined with $\text{Al}(\text{OH})_3$. The pigment thus obtained has a yellow color and is fast to the action of H_2O , $\text{Ca}(\text{OH})_2$, alc. and light. 3,3'-Dinitro-4,4'-diaminobenzophenone, 3,3'-dinitro-4-chlor-4'-aminobenzophenone, "3,3'-dinitro-4-amino-4'-chlorsulfobenzid," 3,3'-dinitro-4-aminobenzophenone, 3,4'-dinitro-4-aminobenzophenone, 3-nitro-4-amino-4'-methoxybenzophenone, 3-nitro-4-amino-4'-chlorobenzophenone, and 3-nitro-4-amino-2,4-dichlorobenzophenone give similar pigments.

Varnish resin. B. T. BROOKS. U. S., 1,167,264, Jan. 4. Melted colophony is treated with H, using Ni as a catalyst, until it has an I no. of not more than 20. This renders it stable against oxidation even in thin films.

Lacquer. O. SCHMIDT, T. EICHLER and O. ALLEMAN. U. S., 1,166,790, Jan. 4. A lacquer for use on wood or metal or other materials is made by dissolving nitrocellulose or dammar, copal or other resins (with or without linseed oil to reduce the brittleness of the lacquer film) in a mixt. of methyleyclohexanone, and benzene or ligroin.

Furniture polish. H. S. THORPE. U. S., 1,166,494, Jan. 4. A mixt. is formed from vinegar 1 gal., paraffin oil 2 qts., kerosene 2 qts., alc. 2 qts., glycerol 8 fl. oz., butter of Sb 8 fl. oz. and oil of mirbane 8 fl. oz.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

The separation of the saturated and unsaturated fatty acids by means of their ammonium salts. HENRIK BULL AND MIKAL FJELLANGER. *Tidskrift Kem. Farm. Terapi* 12, 366-8(1915).—Acetone soln. of the acids is warmed to 40° and treated with a few cc. concd. NH_4OH . This is allowed to stand 3 hours at 17° after which 10 cc. acetone is added and the soaps are filtered by aid of suction and washed 5 times with 5 cc. acetone. The acetone and excess NH_3 are driven off on a water bath. When the acetone is all removed the residue is covered with 5 cc. 80% alc. and warmed 15 min. This material may be used for acid and iodine nos.

A. R. ROSE.

Conservation of lubricants. D. HOLDE. *Seifenfabr.* 35, 982-4(1915).—Discussion of substitutes and measures for regulating the use and consumption of the various lubricants.

E. SCHERUBEL.

Hydrocarbons in fish-liver oils. D. HOLDE. Zehlendorf. *Chem. Ztg.* 40, 14 (1916).—H. thinks that Mastbaum (C. A. 10, 285) failed to supply sufficient tests to prove that the unsapond. oils are not higher alcohols.

J. H. MOORE.

Alfalfa. VI. Alfalfa seed oil. C. A. JACOBSON AND AUGUST HOLMES. *J. Am. Chem. Soc.* 38, 480-5(1916); cf. C. A. 8, 3827.—The seeds showed 3.43% ash, 11.39% Et_2O ext., 10.52% crude fiber, 6.35% moisture, 32.43% carbohydrates, etc., and 35.88% crude protein. For extn. of large amts., gasoline, $b_{\text{m}} 65-95^\circ$, was used instead of Et_2O , the yield of ext. being only 1.92% less. The oil thus obtained showed n_D^{20} 1.4783 to n_D^{20} 1.4587, d_4^{20} 0.9117, sapon. no. 172.3, I no. 154.2, acid no. 2.85, acetyl value 19.8, Reichert-Meissl no. 0.40, unsaponifiable matter 4.40%, glycerol 1.97%, sapon. no. of acetylated oil 192.2. There are practically no volatile fatty acids and no lactones in the free acids; 92.5% of the oil consists of insol. fatty acids (from lauric

upwards) with a neutralization value 191.5, mean mol. wt. 293, sapon. no. 189.9, I no. 169.5, giving 17% solid bromides by the Hehner-Mitchell test. They consist of 90.4% liquid and 9.6% solid acids. The liquid acids consist of oleic, linoleic and linolenic acids (in the proportion of 3.3, 73.2 and 23.5%, resp., calcd. from the oxidation products) and the solid acids of carnaubic, daturic and possibly behenic acids.

CHAS. A. ROULLER.

Fish oil stearin and olein. M. TSUJIMOTO. *J. Chem. Ind. Japan* 18, 1062-72 (1915).—These products are obtained by the distn. of the fatty acids of Japanese herring oil. A mixt. of the two is used for soap purposes. The lathering nos. as detd. according to Stiepel are smaller than those for tallow soap. The consts. for stearin, olein, and soap-stock fatty acids are, resp., as follows: titer, 52°, —, 39.5°; neutralization no., 214, 170, 197; sapon. no., 214, 191, 210; I no., 17, 63, 38; unsapon. matter, —, 4.7, 1.8%.

E. SCHERUBEL.

Detection of vegetable oil in animal fats. J. MARCUSSEON AND H. SCHILLING. *Mitt. kgl. Materialprüfungsamt.* 32, 506-9 (1915); *Chem. Ztg. Rep.* 39, 377; *J. Soc. Chem. Ind.* 34, 1152-3.—Vegetable oils may be detected by a simple combination of the digitonin reaction and phytosteryl acetate test. The oil or fat is shaken with a hot alc. soln. of digitonin, and the resulting digitonide sepd., washed with Et₂O and converted into the acetate by heating with Ac₂O. In the presence of pure vegetable oils the crude acetate will have a high m. p. approximating that of phytosteryl acetate, while in the presence of animal fats the m. p. of the cholesteryl acetate will be const. after 2 recrystns. and will not exceed 114°. Should the m. p. exceed 116° the presence of vegetable oil is certain. Mineral oil does not interfere with the test, and 0.5% of vegetable oil may be detected in mixts. contg. mineral oil.

E. J. C.

Tortelli-Jaffe's color reaction for marine animal oils. M. TSUJIMOTO. *J. Chem. Ind. Japan* 18, 3168 (1915).—The reaction is negative with vegetable and terrestrial animal oils. Marine animal oils mostly give the reaction. With fresh oils the green color has been obtained but old and inferior samples showed negative or indistinct color. By refining, however, the coloration can usually be produced. The fatty acids of marine animal oils, as well as their distillates, also give the reaction, but this is not the case with old oils. Unsataponifiable matter and highly unsatd. fatty acids do not appear to have any relation to the reaction. With hardened fish oil indistinct colorations have been obtained which were not decisive for the detection of fish oil.

E. SCHERUBEL.

Custom-house investigation of fatty vegetable oils by means of the hydrometer. ERNST FISCHER. *Chem. Ztg.* 39, 975-7 (1915).—Owing to surface tension a given hydrometer will not give correct readings even with oils of the same d. The amt., S , by which the instrument is lowered by the meniscus, expressed in units of d., is calcd. by the formula $S = s^2(U \cdot a^3/G^2)$, in which s = density of the oil, U = circumference of the spindle, G = wt. of hydrometer, and a^3 = the capillary const. In order to det. the proper corrections a series of careful detns. was made at 10, 20 and 30° with pure olive, almond, peach seed, peanut, flaxseed, cottonseed, sesame, rape, hemp, poppy and walnut oils, and the results tabulated. The conclusions are that for practical purposes the surface tension is sufficiently const., the av. capillarity const. at 18° is 3.58, and the correction of the d. for each degree above or below 15° is 0.0007. A brief bibliography is given.

J. H. MOORE.

Catalytic bleaching of palm oil. S. G. SASTRY. *J. Chem. Soc.* 107, 1828-31 (1915).—The method employed by S. consists in blowing air through the oil at a temp. of 80-90° in the presence of catalysts. These consisted of the oxides and salts of Mn, Co, Ni, Fe and Pb. No attempt has yet been made to study the chem. changes that

take place. The best catalysts were found to be the salts of Co and Mn; borates were better than other salts. The amts. used were 0.01 to 0.02% and the time required from 2 hrs. in the case of Co borate to 10 hrs. in the case of Ni borate. At the end of 15 months no color had appeared in any of the oils which had been bleached. Two tables of results are given. E. SCHERUBEL.

The ability of colophony to combine with its solvents, especially with the hydrocarbons of petroleum. L. PAUL. *Seifensieder-Ztg.* 42, 393-5, 412-3, 434-5(1915).—Rosin freshly pptd. from its Na soap when stirred with 90% alc. absorbs some alc. and forms a substance which gives off the odor of alc. and is plastic. This plasticity is lost after a time. By distg. a soln. of rosin and petroleum most of the latter is removed but a small portion remains combined at 300-340°. Good evidence of the ability of colophony to combine with hydrocarbons is shown in the behavior of its Ca salts. These are almost completely sol. In distg., rosin oil is formed only at a high temp., and the residue forms a dark brown mass which dissolves in 15 to 20 times its vol. of the fraction of petroleum b. 275-300° and which upon cooling forms a rubbery mass. When $C_6H_5NO_2$ is used as the solvent a substance similar to vaseline is formed. The Na salt of rosin behaves in a similar manner. By heating it to 120° with 10 parts of petroleum a transparent mass is formed which gives off the odor of petroleum. By using the fraction of petroleum b. 170-250° to dissolve the Na soap and heating to 115° a sepn. of the above mass takes place and when this sepd. mass is distd. at a high temp. the combined petroleum is given off. The NH_4 salt of rosin is also sol. in 10 vol. of petroleum with heating but there is no sepn. at 115°. Upon cooling, however, there is one. E. SCHERUBEL.

Manufacture and cost calculations of soaps and washing powder during war time. J. *Seifensieder Ztg.* 42, 1014-5(1915).—Formulas and costs of washing powders contg. from 2 to 30% of fat. E. SCHERUBEL.

Talc in soap manufacture. P. ROHLAND. *Seifenfabr.* 35, 997-9(1915).—Discussion of the use of talc as filler in place of potato flour both in laundry and toilet soap. Several formulas are given. Cf. C. A. 9, 2322. E. SCHERUBEL.

A biochemical reaction for rancid fats (VINTILESCU) 12. Lubricating-oil testing machine (SLAUGHTER) 1.

Rendering carbon tetrachloride miscible with dilute soap solutions. L. FRANK and G. FENDLER. U. S., 1,165,498, Dec. 28. CCl_4 (or other halogen derivs. of hydrocarbons) is emulsified with an aq. soap soln. containing not more than about 10% its wt. of soap, calcd. as fatty acid. This emulsion may be dild. with 200 times its vol. of 0.5-1.0% soap soln. as a detergent.

Cleansing composition. J. T. FREESTONE and W. & F. WALKER. Brit., 19,229, Aug. 29, 1914. A tablet for washing clothes, etc., is composed of an alkali perborate, a washing alkali such as soda ash, and a liquid hydrocarbon such as petroleum spirit, with or without borax. The ingredients are mixed as powder with the hydrocarbon absorbed therein, and pressed to form the tablet, which is encased in paraffin or like wax. Cf. C. A. 9, 1257.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Report on sugar and molasses. W. E. CROSS. *J. Assoc. Official Agr. Chemists* 1, 314-7(1915).—A number of chemists detd. the % of H_2O in a sample of raw sugar

by the official method (Bur. Chem. Bull. 107, Rev., p. 64), by use of the Abbé refractometer and the immersion refractometer. Their results indicate that the refractometric methods are not entirely satisfactory. H_2O in 1 sample of centrifugal molasses and 1 of blackstrap molasses was detd. by the official method (*loc. cit.* p. 65), and with the immersion refractometer. The results are too meager to warrant definite conclusions, but indicate that the quick, more convenient refractometric method may be made satisfactory. Results of 5 chemists on the official (*loc. cit.* p. 40) and a proposed "direct" polarization method for the detn. of the % of sucrose in molasses are given, with the recommendation that all these methods receive further study. H. S. BAILEY.

Determination of sucrose in beet molasses by the double polarization method, using invertase as hydrolyst. E. SAILLARD. *Circ. hebd. Fabr. Sucre France* 27, No. 1371, 4(1915); *J. Soc. Chem. Ind.* 34, 1023; cf. *C. A.* 9, 1404.—Commenting upon the invertase process of double polarization for the detn. of sucrose in beet molasses, used by Ogilvie (*C. A.* 5, 1686; 6, 1073) S. suggests that it may give inexact results on account of the commencement of alc. fermentation. It is preferable, he claims, to use an aq. soln. of the enzyme rather than to add yeast directly to the sugar soln. E. J. C.

The relation between the crystal content of raw sugars and ash rendement according to the methods of Herzfeld and Koydl. L. RADLBERGER. *Oesterr.-ung. Z. Zuckerind.* 44, 97-103(1915).—By the observance of exact working conditions, especially the maintenance of const. temp. and satisfactory satn. of wash soln., values may be obtained for the crystal content of raw sugars as detd. by Koydl's method (*C. A.* 1, 112) which are quant. The method of Herzfeld-Zimmermann (*C. A.* 6, 1548) also gives useful values if exact working conditions are maintained. R. finds in using this method that the crystal content is a function of the time of centrifuging. Insofar as the relation of the detn. of crystal content to rendement is concerned, it was found that sugar of medium grain size shows very good agreement. When the crystal content values according to both methods agree exactly, it follows that in this case the value five for the rendement is correctly chosen. In other words, that here five parts of non-sugar really prevent one part of sugar from crystallizing out. Sugars of large size grain gave a figure, according to both methods, which was smaller than the rendement, while those of small size grain, gave a greater value. It was, therefore, necessary in the first case to choose a larger, and in the latter, a smaller factor for the rendement in order to bring about an agreement of both detns. E. A. TSCHUDY.

The value of the relation between ash rendement and crystal content in sugar refining. T. KOYDL. *Oesterr.-ung. Z. Zuckerind.* 44, 265-72(1915).—A detailed discussion of the various points covered by the work of Radlberger. Cf. preceding. E. A. TSCHUDY.

The making of sugar in Louisiana with special reference to white sugar. VII. CHARLES E. COATES. *Louisiana Planter* 56, 60-2(1916); cf. *C. A.* 9, 3375.—A discussion of the coloring matter of cane juice and methods for its removal. A. G.

Cane juice clarification. MAX SCHNELLER. *Louisiana Planter* 56, 44-6(1916).—The amt. of Na phosphate usually employed removes only a small part of the lime salts; 50 times the amt. used would be required for complete removal. The pptn. at slight acidity is incorrect as $Ca_3(PO_4)_2$ is sol. in dil. acids, even in AcOH. When using large quantities of Na phosphate, the color of the clarified juice was much improved. The color was not restored upon the addition of large amts. of Ca or Mg salts which sometimes cause discoloration of juices. The addition of an amt. of ferric salt found in a dark-colored juice did not materially affect its color. Ferric salt added to sucrose or glucose solns. produced no darkening. It was thought possible that the darkening is due to some organic coloring matter which might have been pptd. by the voluminous

ppt. of $\text{Ca}_3(\text{PO}_4)_2$. As a large amt. of Na phosphate would be too expensive in actual practice Na aluminate was used as the clarifying agent. The clarified juice in this case was affected by a small amt. of iron giving a noticeable darkening when slightly alk. and a dark brown coloration when reacidified to 0.02-0.1 N cc. The color effect of the juice was found to be due to the presence of compds. belonging to the polyphenols or the phenolcarboxylic acids, usually classified as "tannins" because of the delicate iron reaction. A wide range of literature is cited in connection with the occurrence of these substances in sugar cane. By heating at higher alkalinity invert sugar solns. are colored dark by glucinic acid, apoglucinic acid and other humin-like decompn. products, so that a second source of polyphenol compds. occurs in processes in which the destruction of reducing sugar by heating with lime is practiced, that is, in the beet sugar carbonatation process and the Batelle process. The danger to the color of juices arising from the formation of such polyphenol compds. is at first concealed by the pptn. of Fe in the double carbonatation process, but the dark color reappears gradually as the metal is redissolved on evapn. in iron containers. Alkalinity should be avoided when evapg. in iron. The care employed in removing iron by double carbonatation or a similar process would not only be wasted, but more harm may be done by formation of glucinic acid, the amt. of which is likely to be far in excess of the small quantities of phenol compds. naturally present in juices. The Fe content of the liquors becomes comparatively harmless after elimination of the objectionable polyphenol compds. Lead subacetate is a pptnt. of most polyphenols while hide powder, specially prepared Al oxide and animal charcoal used in the analysis of tanning materials absorb besides tannin all the other polyphenols. The only practical method noted is the charcoal process sometime ago discarded in the beet sugar industry and now limited to refineries.

A. GROSS.

White sugar manufacture by the Battelle process. E. E. BATTELLE. *Intern. Sugar J.* 17, 357-9(1915).—B. claims that while the Steffen process has given excellent results in the beet-sugar industry, it has given no evidence of successful application in the cane-sugar house. This is due to the large quantities of glucose which combine with the caustic lime used and then decompose to sol. lime salts reducing the purity to such an extent that the latter is of but little higher purity than the original molasses under treatment. B. removes the glucose from the cane juice or molasses by previous treatment. The juice is heated to, or nearly to, the b. p. with from $1\frac{1}{2}$ to $3\frac{1}{4}\%$ of lime in carbonatators. This constitutes the fundamental principle of the process; from this stage onwards, the procedure is precisely the same as that of the beet-sugar factory.

A. GROSS.

The sulfur utilized in the sulfitation of thick-juice and run off sirups. C. L. BRUNINGS. *Intern. Sugar J.* 17, 365-7(1915).—A calcn. of the extent to which SO_2 introduced for the neutralization of the free alkali of thick juices and run off sirups is utilized. Data were obtained from five Holland beet-sugar factories. It was found that the factories sulfiting only thick juice obtain a higher utilization than those treating the run off sirups, while the utilization when both thick juice and run off sirups are treated is more unfavorable than with thick juice sulfitation alone. The sulfitation of thick juice is continuous whereas that of run off sirups is intermittent, in which latter case at intervals more S is burned than is necessary, the efficiency value being thus decreased. By the regulation of the air and by varying the amt. of the charges according to the SO_2 required, the utilization can be raised.

A. GROSS.

History of the beet sugar industry in Germany during the early stages of its development. C. SCHEIDLER. *Z. Ver. Zuckerind.* 65, 447-513(1915). W. L. B.

Drying beets. H. CLAASSEN. *Z. Ver. Zuckerind.* 65, 331-42(1916).—A lecture

and discussion. Much of the information has appeared elsewhere (see 3 articles, C. A. 10, 128). W. L. BADGER.

The extraction of sugar from molasses by lead oxide and baryta. DAUDE. *Z. Ver. Zuckerind.* 65, 346-68(1915).—A digest of patents. W. L. BADGER.

The colloidal clay process for purification of the waste waters of sugar factories. P. ROHLAND. *Oesterr.-ung. Z. Zuckerind.* 44, 112-3(1915).—By treating the total effluent of a sugar factory, composed of beet-wash, diffusion, condenser and filter-press waste waters, with colloidal clay, it was possible completely to clarify and deodorize the water. The colloidal clay after adsorption of the colloid matter (albumin, carbohydrate, etc.), in the waste waters, can be utilized as fertilizer. E. A. TSCHUDY.

Determination of reducing sugars (SCALES) 7. Lead nitrate as a catalytic fertilizer for sugar beets (GREISENEGGER) 15. Flameless combustion (Pokorny) 21.

KOPFESCHAAR, E.: *Evaporation in the Cane and Beet Sugar Factory.* New York: Van Nostrand Co. 126 pp. \$2.50.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Contribution to the knowledge of adsorption (in leather). I. V. KUBELKA. *Collegium* 14, 389-408(1915).—K. states the importance of the study of the adsorbent properties of hide, both to the theoretical explanation of the process of tanning and to the practical control of the process. An abstract of the work of previous investigators is given. K. used as the adsorbent unchromed Freiberg hide-powder, and as liquids to be adsorbed, solns. of formic, acetic, propionic and butyric acids. Water for diln. was distd. in special app., and was free from CO₂. For titration, Ba(OH)₂ soln. of normality from 1/10 to 1/100 was used, with phenolphthalein indicator. In a 200 cc. flask, 5-6 g. of hide-powder was shaken with 100 cc. of the acid soln., the amt. of acid adsorbed being detd. by titrating the soln. before and after contact with the hide. With each acid, the time of the reaction and the concn. of the soln. were varied between wide limits. Results are tabulated and shown graphically. K. concludes (1) that when the 4 acids act on hide-powder, changes of concn. take place, which quickly proceed to an equil. condition, these reactions being reversible within the whole range of the series of expts.; (2) the speed of reaction is great (more than 1/2 of the whole change taking place in the first 5 sec.), diminishing with increase of concn.; (3) the equil. proportions of the reacting substances may be expressed by the general adsorption formula, whose const. for each acid is detd.; (4) the proportionality of the dissociation const. and the adsorption const. were shown except in the case of formic acid, and for this, it was shown that with increasing diln. the two const. became more nearly proportional. L. B.

Boric acid for deliming. ANON. *Shoe and Leather Reporter* 121, No. 2, 77-9 (1916).—Boric acid may be used for heavy or light classes of leather. An excess would not injure the pelt. A skin delimed with H₂BO₃ has a soft silky grain which is present in the final leather. All the lime may be removed by 1% boric acid calcd. on the drained wt. of the limed pelts. Viewed from the point of chemical strength, or deliming power, boric acid is one of the cheapest deliming agents. J. S. ROGERS.

Modern methods of blacking chrome leather. ANON. *Shoe and Leather Reporter* 121, No. 1, 65-6(1916).—Logwood imparts fullness to the leather when used in conjunction with direct blacks. Any free acid in the logwood should be neutralized

by adding ammonia, sal soda or borax, changing the original brown tinge of the liquid to a violet-red. A full black may be obtained by simply drumming chrome leather with a soln. of black dye, but if the flesh side is desired blue, the whole may be dyed blue with a soln. of acid color adding a little ammonia and logwood or gambier, and then the grain side dyed black by brushing on a soln. of basic black feebly acidified with acetic acid. Chrome leather should always be neutralized before blacking it. With direct dyeing chrome blacks, the leather may be fat-liquored either before, after, or during the dyeing. In the case of direct blacks which are not fast to alkali, the fat-liquoring should precede the dyeing. In this case the leather should be rinsed before drying. Acid blacks dye chrome leather a rich lasting black and the color penetrates well. A proper amt. of gambier used with or before an acid black gives a desirable fullness to the leather. Good penetration is obtained by combining an acid black and a direct chrome black. A satisfactory and durable black depends on proper dyeing and not on coloring matter in the finish. However a finishing material may be added to the dye when the grain side is dyed after the leather is dry. Egg yolk is one of the best materials for fat-liquoring light chrome leathers. Some of the processes are described in detail.

J. S. ROGERS.

Waterproofing leather. R. A. MARR. U. S., 1,166,845, Jan. 4. Leather is immersed in a mixt. of paraffin, rosin and diatomaceous earth, the temp. of which is first maintained at about 101° and then allowed to fall as impregnation is effected. The diatomaceous earth is used to fill the pores of the leather and make it more resistant to organic acids.

Waterproofing leather. R. A. MARR. U. S., 1,166,846, Jan. 4. $C_{10}H_8$ is added to the impregnating mixt. of the preceding pat. and the process is carried out in the same manner.

Flexible waterproof leather. J. W. BARBER. U. S., 1,167,326, Jan. 4. Leather impregnated with petrolatum and paraffin, with a larger % of the paraffin in the superficial than in the body portion, is prepd. by successive immersion in mixts. of the petrolatum and paraffin, containing successively increasing amts. of the latter.

Flexible waterproof leather. J. W. BARBER. U. S., 1,167,327, Jan. 4. Leather is treated successively with different mixts. of viscous and solid H_2O -proofing substances, each of which contains a larger % of the latter than the preceding bath used, so that it is impregnated with a blended compn. with a larger proportion of solid wax or the like near the surface. This filling prevents passage of H_2O through needle holes made in sewing the leather.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

The rubber industry. I. ANDREW H. KING. *Mel. Chem. Eng.* 14, 23-9(1916).—An historical review of the natural and synthetic rubber industries. Theories of the structure of the rubber mol. and of vulcanization are discussed. II. *Ibid* 71-7.—An outline of factory practice in such processes as washing, drying, compounding, mixing, calendering, frictioning, vulcanizing and the manufacturing of various rubber articles.

E. H.

The future of Para rubber. N. H. WITT. *Gummi-Ztg.* 30, 199(1915).—The commercial future of wild S. American rubbers is discussed. It is doubtful if the production of *Castilloa* rubber will remain profitable, because of the increased production, and the lowering of the cost of plantation rubbers. By educating the natives

and lowering the tariffs in Brazil, Para rubber should be able to hold its own in the markets on account of its superiority in some respects over plantation rubbers. The advantage of Para rubber over plantation rubber is due to the youth of the plantation trees, the methods of collecting and coagulating the latex, and the difference in climates. The main reason for the lower quality of plantation rubbers is probably the fact that Wickham did not bring the proper seeds to the east. WILLIAM F. ZIMMERLI.

New simplified Schadt process for the preparation of rubber. J. G. C. VRIENS. *Mededeelingen van de Adviseur der A. V. R. O. S.* 1914, 51-2; *Bull. Agr. Intelligence* 6, 1064.—According to Schadt's new process, already used in several places in the Dutch East Indies, a thin layer of latex is spread on tin plates with recurved edges. After some time, the water having evapd., there remains only a thin coating of rubber. The films thus obtained are smoked by revolving them in a drum covered with perforated sheet-iron, and are subsequently compressed into blocks. On the second day after tapping, the rubber is ready for dispatching. The rubber thus retains the original latex elements, while the cost of production is reduced to a minimum. It appears that this process is a step in the right direction towards obtaining uniformity of the product. E. J. C.

The acetone extraction of gums and products of rubber. A. HUTIN. *Ann. chim. anal.* 20, 212-3(1915).—Unless the acetone extract is dried *in vacuo*, it increases in wt. constantly, to even more than 20%. Drying *in vacuo* gives const. wt.

P. M. GIESY.

Determination of total sulfur in the products of the rubber industry. A. HUTIN. *Ann. chim. anal.* 20, 214-6(1915).—"Total sulfur" is not an exact term; its meaning should be specified in any contract. H. gives the following method for its detn.: Place 1-2 g. of the sample, milled to 1 mm. thickness, in an 80 mm. crucible, and cover with a funnel. Add 30 cc. S-free HNO_3 in the cold in portions of 2-3 cc. The action is very violent, and if the rubber catches fire, the detn. is lost. Evap. the soln. to a sirupy consistency on the H_2O bath; add 2-4 cc. S-free NaOH soln., drop by drop, to neutralize the acid, then pure calcined magnesia to make a very thick paste. Evap. the paste to dryness, at first on the water-bath and then in an oven or air-bath at 140° ; when well dried, calcine over a small Bunsen flame. Since the mixt. is explosive, too rapid heating is dangerous. Take up the mass with H_2O , heat on the water-bath, filter, and wash, taking care to crush all lumps. From a 1 g. sample 300 cc. soln. should be obtained. Conc. this to 100 cc., acidulate with HCl , boil and ppt. with BaCl_2 . The soln. should be colorless; if it is not, the calcination has been incomplete.

P. M. GIESY.

Observations on the subject of the determination of total chlorine in rubber substitutes. A. HUTIN. *Ann. chim. anal.* 20, 241-2(1915).—0.2-0.5 g. of the substitute is covered in a porcelain crucible with the usual mixt. of Na_2CO_3 and KNO_3 and the mixt. heated slowly until quiet fusion results. When cold, the melt is dissolved in H_2O to which HNO_3 has been added, and the Cl detd. by titration. P. M. GIESY.

Sterilin (rubber substitute). E. MARCKWALD AND F. FRANK. Berlin. *Chem. Ztg.* 39, 927-8(1915).—An account of tests made to show the resistance of this substance to H_2O , acids, alkalis and salts, in order to det. its value as a protector for the hands in chem. industries and surgical operations. The results show it to be a valuable substitute for rubber gloves in many cases. J. H. MOORE.

Molding bakelite. G. PONCHT. *Am. Machinist* 43, 1113(1915).—The manufacturing advantage of bakelite over hard rubber is that all subsequent machining operations, such as threading, milling and drilling, are eliminated. G. G. F.

Vulcanizing rubber. P. I. MURRILL. U. S., 1,166,777, Jan. 4. Rubber cured by treatment with S_2Cl_2 and gasoline which has been freed from olefins by treatment with Cl_2 , Br_2 , I_2 or S_2Cl_2 and distn. The absence of olefins avoids injury from malodorous compds. which shorten its life and which are formerly commonly present in gasoline.

Revulcanizing rubber. R. B. PRICE. U. S., 1,166,784, Jan. 4. Vulcanized rubber is heated slightly under a pressure of about 3000-4000 in., after exhausting the gases from it, then vulcanized by heating and cooling to check surface vulcanization. Cf. C. A. 9, 2823.

Devulcanizing rubber. H. J. MAYERS. U. S., 1,167,359, Jan. 11. Devulcanized by heating with oil of pine which has been deresinated and purified by redistg. the oil (obtained originally by distg. pine wood, an oil of 0.88-0.96) at about 100° with H_2O and $NaCl$, amyl acetate and oil of citronella.

Vulcanizing rubber tires on cores and stretching the sides and edges. J. H. COFFEY and J. H. COFFEY, JR. U. S., 1,166,326, Dec. 28.

Uniting metals with hard rubber. G. C. KNAUFF. U. S., 1,165,755, Dec. 28.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 505 Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.

Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.....	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,
Box 505, Washington, D. C.

14. Water, Sewage and Sanitation....	791		
15. Soils and Fertilizers.....	795		

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

L. C. JONES.

A new pyrometer protector. FINK. *J. Gasbel.* 58, 595-6(1915).—Into the space whose temp. is to be measured is inserted a tube, closed at the end and larger in inside diam. than the outside diam. of the thermocouple. A flange on this tube and another on the pyrometer tube are connected by bolts, and the pyrometer is only inserted part way into the space. It seems to be intended that the pyrometer should be placed to measure a temp. less than the full temp. in the app., and a correction factor applied. It is claimed that temps. up to or over 1200° can be measured with base metal couples by only inserting them so far that they will not be exposed to temps. over 600°. The flanges are supposed to increase the usefulness of the device by directing currents of hot air away from the cold junction.

W. L. BADGER.

Space models for introduction into the study of eruptive rocks. PAUL NIGGLI. Leipzig. *Centr. Min. Geol.* 1915, 449-65.—The desirability of constructing space-models so as to gain an accurate idea of the field relations in ternary and more complicated systems is pointed out and descriptions given of a number of models designed by N. for this purpose.

E. T. WHERRY.

Structure models according to W. H. and W. L. Bragg. O. MÜGGE. Göttingen. *Centr. Min. Geol.* 1915, 545.—A brief description of models which have been constructed by Bartels, of Göttingen, to bring out the structures which have been demonstrated by B. and B. and others to exist in crystals of diamond, sphalerite, halite, pyrite and calcite. The simplest cube is multiplied by 8 so as to show the relations in neighboring portions of space, and the calcite structure is also extended in certain directions to bring out the relations more clearly.

E. T. WHERRY.

A new polarization instrument. MAX BAUER. Marburg. *Centr. Min. Geol.* 1915, 513-6.—A description with figures of a special microscope, using a Norrenberg polarizer, which has the advantage that observations can be made in parallel light and in convergent light without the many changes in the lens system necessary in the usual form. The main portion of the microscope tube, comprizing stage, objective and eyepiece, is pivoted so that it can be swung into two different positions; in one of these the parallel polarized light enters as in the ordinary microscope, while in the other a condenser beneath the stage and an accessory eyepiece above the standard one, yield convergent light and permit the observation of interference figures. The apparatus is made by Leitz.

E. T. W.

Pipets especially adapted for use with alkaline pyrogallol. R. P. ANDERSON. *J. Ind. Eng. Chem.* 8, 133-5(1916); cf. *C. A.* 10, 728.—A modified Orsat pipet is described which can be used with a concd. pyrogallol soln. (25 g. of pyrogallol in 100 cc. of KOH of 1.55 d.), and in which the formation of the ppt., characteristic of alkaline pyrogallol, is not objectionable until the reagent is nearly exhausted. The specific absorption of the above reagent in the new pipet is greater than in the Hempel pipet, and the new form is more convenient to manipulate.

E. W. BOUGHTON.

Design of a polariscope observation tube. D. W. ROCKEY. 33(1915).—The design (see fig.) consists essentially of a metal-cased glass tube *A* makes possible the better cleansing, using acid if des corrosion. The metal casing *B* protects the glass from breakage. flattened sufficiently to prevent rolling. The tube *A* should be a

diam. to avoid the bad effects of capillarity. The threading of the tube should be a quadruple thread with at least 1 cm. pitch, which allows the tube to be turned one turn. The casing should have a shoulder extending out from the end at *E* for about 5 mm. The casing *B* being attached to both shoulders, it can be working loose and out over the end of the glass tube.

Note on a gas-pressure regulator. ALFRED F. JOSEPH. P. 254-55(1914).—The regulator was designed for use with high and low pressures. It can be used to reduce to any desired pressure. The gas enters

enters through a walled rubber tube which carries the armature of a telegraph. When the armature is pulled down, the pressure is nearly shut off. The regulator is made of glass tubes and a solenoid. When the pressure increases, the acid is forced up the tube and completes the circuit and causes the armature to move.

The large vessel *H* acts to take up small variations of pressure. *K* is a weight. A weight may be used to advantage on the bar *A*. The apparatus is in use for over a year, keeps the pressure at 5 cm., the amplitude of variation being only about 1 mm.

The modification of the Lunge shaking flask. A new gas buret. *Chem. Ztg.* 40, 39-40(1916).—The modified nitrometer is designed for the measurement of the substance in H_2SO_4 by shaking. It consists of 2 parts connected by a joint held in place by a steel spring. The upper part is a double-bored glass cup for adding the H_2SO_4 and tube for connecting with any suitable apparatus. The lower part is like the reaction bulb of du Pont's nitrometer. When lowered to the bottom cock which is closed, the substance introduced into the wide mouth, the slip-joint closed and secured by the spring, the H_2SO_4 is hastened by shaking, the lower cock opened and Hg allowed to enter the bulb and the gas measured as usual. The buret resembles a Bunte buret except that the bulb is graduated. The rest of the buret is graduated in both directions, in and out of the bulb, so that if the meniscus is in the bulb the app. may be in either direction.

Evaporating apparatus. OSKAR NAGEL. *Chem. App.* 2, 2(1914).—A brief outline of the principles underlying the Yaryan, Zaremba and Ordway app., and a description of a new app. for the

from potash and soda manuf. It consists of a stack, in the center of the base of which is a nozzle through which the soln. to be evapd. is forced with compressed air. This acts as an injector to draw in the fuel gas through openings in the stack just above the nozzle. The flue gas and steam pass out at the top, the soln., concd. to the solidifying point when cooled, falls to the base and flows out into a trough in which is a revolving cooler to which it adheres as a crust which is removed by a suitable scraper. The absorption of heat is so rapid that with MgCl_2 solns. the temp. never rises above $125\text{--}30^\circ$. Cf. Schröder, *C. A.* 10, 297.

J. H. MOORE.

A centrifuge. A. GAWALOWSKI. *Z. anal. Chem.* 54, 549(1915).—The app., devised for preps. to be kept out of contact with metal, is shown in the accompanying sketch. The removable, perforated wooden drum *B* is rotated in the wooden vessel *A* by means of the hand crank *C* or an air, gas, or H_2O motor. Gauze, linen, filter paper, etc., may be used as a lining for *B*. The removed soln. runs out at *a*.

F. W. SMITHER.

Apparatus for rapidly testing substances used against poisonous gases. E. KOHN-ABREEST. *Compt. rend.* 161, 310-3(1915).—K. describes, with a sketch, a simple piece of app., by means of which a definite vol. of a mixt. of air and poisonous gases can be slowly aspirated over a plug of cotton-wool impregnated with a soln. of the absorbing agent to be tested. A table is given showing results of tests of mixts. of Cl and air with dry and moist cotton, Na_2CO_3 , NaHCO_3 , $\text{Na}_2\text{S}_2\text{O}_3$, NaI or KI , $\text{KI} + \text{Na}_2\text{CO}_3$, $\text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{CO}_3$, $\text{NaHCO}_3 + \text{Na}_2\text{S}_2\text{O}_3$, $\text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{CO}_3 + \text{glycerol}$, $\text{Na}_2\text{S}_2\text{O}_3 + \text{NaHCO}_3 + \text{glycerol}$. In each case 250 cc. of the mixt. used was slowly aspirated at about the same rate as the inspiration of air during breathing. For mixts. containing 1 in 1000 or less of Cl , cotton-wool alone, either wet or dry, absorbed all of the Cl ; only when the Cl rose to above 1% was any difference noted among the absorbents. With concns. greater than 1% a satd. soln. of Na_2CO_3 absorbs the Cl very energetically; NaHCO_3 soln. does so only moderately. When $\text{Na}_2\text{S}_2\text{O}_3$ is used, SO_2 is liberated, necessitating the use of Na_2CO_3 for its absorption. The addition of glycerol to the solns. serves mainly to prevent evapn., and to render more uniform the absorption of the Cl . KI soln. (30%) acts very energetically as an absorbent, the I formed being fixed on the cotton, probably as ICl .

F. W. SMITHER.

Power briquetting press. ANON. *Iron Age* 97, 372-3(1916).—The press, described in detail with illustration, will be used by the Wickwire Steel Co., Buffalo, for briquetting waste material not suitable for use in the blast furnace on account of its fineness. The design closely resembles that of the Breuck-Kretschel press; it is of the lever, power-actuated kind, known as the toggle type of press. Power is applied by means of a belt. The noteworthy features are the manner in which the safeguarding against breaking or unduly stressing the principal members of the press has been provided for, the absence of registering holes or plungers, and the automatic character of the movements, from the filling of the molds to the discharge of the finished briquet, which require the least intelligent class of labor.

F. W. SMITHER.

The Ferranti water heater. ANON. *Electrician* 76, Suppl. 106.—This is an elec. heater so constructed as to be inserted into a tube or pipe line, there being a pipe connection at either end of the heater. The heater is particularly useful in exptl. work requiring a constant supply of heated H_2O of a definite temp. The small size heater shown consumes 350 watts maximum. With this wattage it will heat 3.55 l. H_2O per half. hr. from 10° to 45° .

C. G. F.

A tailings sampling device. A. M. SHAW. *Eng. Mining J.* 101, 223(1916).—An auger for taking samples from depths not exceeding 8 to 10 ft. comprizes the following material: one $1\frac{1}{2}$ -in. Snell ship auger with screw; upset stem, cut off to 18 in. over-all,

and thread upset end for $\frac{3}{8}$ -in. standard pipe; one length $\frac{3}{8} \times 6$ (thread both ends); four lengths $\frac{3}{8}$ -in. $\times$ 2 ft. galvanized pipe; two lengths $\frac{3}{8} \times 3$ in. galvanized pipe (thread one end); eight $\frac{3}{8}$ -in. couplings; one $\frac{3}{8}$ -in. galvanized Fe tee; two 8-in. Cochran or St. All pipe threads should be cut full standard depth, rubbed free from greased. The tee with the two 3-in. lengths of pipe forms a handle use the auger is shoved down, without turning, to the elevation from is desired, a few turns are made with a slight pressure on the stem and drawn. In use the steel plunger is screwed to the 18-in. length of $\frac{1}{2}$ to the bottom of the brass "core barrel." The instrument is for dump and successive lengths of the $1\frac{1}{4}$ -in. and $\frac{1}{2}$ -in. pipe added until is reached, when the plunger is withdrawn far enough to insure clearing the core barrel. Care should be exercised to see that the slot is free of plunger until ready to take a sample. Soil samples have been taken of 40 ft. with a device of this nature.

Gas-washer. T. McDONALD. U. S., 1,167,909, Jan. 11.

Apparatus for cooling and scrubbing gas. L. A. ZÖHE. U. S.,

Carbonating liquids. A. A. PINDSTOFFE. Brit., 19,769, Sep. for impregnating liquids with CO_2 . Cf. C. A. 9, 2333.

Etching hollow articles. DEUTSCHE MASCHINENFABRIK AKT.-G. Jan. 10, 1914. A suitable app. is specified.

2. GENERAL AND PHYSICAL CHEMISTRY

WILLIAM D. HARKINS AND E. B. MILLARD.

Revision of the atomic weight of neodymium. II. G. P. BAILEY, COMB. O. J. STEWART AND H. C. CHAPIN. *J. Am. Chem. Soc.* 38, C. A. 5, 645.—After 158 series of crystals of $\text{Nd}(\text{NO}_3)_3$ from HNO_3 material was tested spectroscopically. From the photographs and known amounts of Sm and Pr had been added the amount of each of the elements, and a correction applied. In the material finally used the ratio between 0.6% and 0.0%, the Pr was between 0.2 and 0.0%, the amount of one element accompanying the smaller of the other. The mean ratio $\text{NdCl}_3:\text{Ag}$ and 15 determinations of $\text{NdCl}_3:\text{AgCl}$ gave the atomic weight. The average of this result and that found in the earlier work is 144.26 and $\text{Cl} = 35.457$. Since the ratio $\text{Ag}:\text{AgCl}$ which could be calculated was 0.752632 and that found by Richards and Wells (1908) was 0.752632, inclusion by the AgCl or from loss of AgCl were probably absent.

Stoichiometry. ROBERT KREMAN. *Fortschritte Chem.* 11, 8. Progress in this field for the second half of the year 1914 is reviewed. Subjects: General properties of unary systems, surface tension, viscosity and osmotic phenomena.

Effect of pressure on polymorphic transitions of solids. P. W. BRIDGMAN. *Nat. Acad. Sci.* 1, 513-6 (1915); cf. C. A. 9, 2479, 2617, 3000.—Pressure on 30 substances, for pressures up to 12000 kg. per sq. cm. The experiments described before.

Supposed allotropy of copper. G. K. BURGESS AND I. N. KENNEDY. *Nat. Acad. Sci.* 3, 657-62 (1915).—A series of experiments by an electric resistance

to that previously used on Fe (*C. A.* 9, 194) except that a calorimeter was used in place of the furnace. The expts. did not show any evidence of the existence of an allotropic modification of Cu such as has been postulated by Cohen and Hulderman (*C. A.* 8, 1223, 2514), and the expts. of C. and H. do not show the existence of such an allotropy. The change in zero value of elec. resistance which they claimed as evidence of allotropy is common to all metals and is related to the hardness of the metal. However, the resistance of Cu in the range from 0 to 100° varies continuously, showing no break at about 70°, and ordinary Cu is most probably not in a metastable condition.

E. B. MILLARD.

Densities and cubical coefficients of expansion of the halogen salts of sodium, potassium, rubidium and cesium. G. P. BAXTER AND C. C. WALLACE. *J. Am. Chem. Soc.* 38, 259-66(1916).—The method employed was the displacement of toluene, and in order to reduce the errors of expt. a very considerable quantity of salt (about 25 g.) was employed. The pycnometer itself was merely a 25 cc. graduated flask with the neck constricted to about 2.5 mm. Especial pains were taken in drying the salts and freeing them from entangled air when immersed in the toluene. The vol. of the flask was found by weighing it with H₂O after the liquid had been set at the mark in the thermostats used for finding the ds. of the solutions in the preceding paper (*C. A.* 10, 303). Data have been computed for the d. of the salts referred to H₂O at 4° for 0°, 25°, 50° and 70° and for the cubical coeffs. of expansion over each of the 3 intervals.

E. B. MILLARD.

Densities and cubical coefficients of expansion of certain substances: arsenious oxide, lead chloride, lead bromide and neodymium chloride. G. P. BAXTER AND C. F. HAWKINS. *J. Am. Chem. Soc.* 38, 266-71(1916).—Two forms of pycnometer were used, one of which is described in *Am. Chem. J.* 31, 220(1904), and is a modification of the T. W. Richards pycnometer for solids; the other was a 50 cc. flask used as described in the preceding abstr. Data are given for 0°, 25° and 50°. E. B. M.

Solidification curve of the system lead nitrate and ammonium nitrate. B. BOGRRCH. *Compt. rend.* 161, 790-1(1915).—NH₄NO₃ has a m. p. of 158°; Pb(NO₃)₂ decomposes. Addition of NH₄NO₃ to Pb(NO₃)₂ greatly increases its stability, though the soln. of the Pb salt takes place very slowly in the melt. The temp. of solidification of mixts. contg. 9 to 55% Pb(NO₃)₂ has been detd. An eutectic point was found at 131° and about 33% Pb(NO₃)₂. Extrapolation of the m. p. curve gave 450 to 470°, as a probable value for Pb(NO₃)₂, assuming the curve does not change slope.

E. B. MILLARD.

Contradictions between calculated and observed solubilities of certain sodium salts. A. COLSON. *Compt. rend.* 161, 787-90(1915).—Solubilities calcd. from the calorimetric expts. of *C. A.* 10, 304, for NaCl do not agree with directly detd. ones. The calcd. values show a max. soly., and the same discordance was found to exist for Na₂CO₃. No explanation has been found.

E. B. MILLARD.

The melting points of "pressed" crystals. MEINHARD HASSELBLATT. Göttingen. *Z. anorg. allgem. Chem.* 93, 75-83(1915).—H. attacks the theory of the melting of solids under non-uniform pressure as developed by Ostwald, Niggli and others. If a cylinder of material be pressed in a bomb with a loose-fitting plunger, there will result an excess of pressure on the solid above that on the liquid. Then, calling π this excess pressure, T the abs. melting temp., v the sp. vol. of the solid, and q the latent heat of fusion, the relation $dT/d\pi = -vT/q$ may be easily obtained by performing an imaginary isothermal cycle. As H. points out, however, the necessary cyclic process is in one sense not reversible, for it is not possible to cause pressed crystals to separate out from the liquid and thereby lift the plunger. Nevertheless the whole cycle may be considered as made up of a number of equil. changes and therefore the thermodynamic

equations are applicable and the formula as given is correct if it be process really takes place in the manner indicated. The validity of is challenged by H., who endeavors to show that crystals under pressure in direct contact with the unpressed liquid. But an indirect equilibrium phase is possible, and a mathematical investigation of such a formula identical in form with that used by Niggli.

The nature of flow in crystalline substances. G. TAMMANN *anorg. allgem. Chem.* 92, 37-46 (1915).—T. discusses the phenomenon of cryst. substances and especially the "local melting" theory of the (cf. preceding abstract). The ordinary formula for the change of form pressure is stated by T. to have been derived from faulty assumption an expt. with ice which shows that the formula does not apply to it under a loose-fitting plunger. The final conclusion reached is that plasticity of cryst. solids lies in the formation of "gliding planes" and this thesis renders unnecessary the postulation of a partial melting during

A theory of chemical reaction and reactivity. Further note. *J. Am. Chem. Soc.* 38, 227-8 (1916); cf. *C. A.* 10, 301.—Polemical (*A.* 10, 300).

The quantum of action. WM. WILSON. Univ. London. *Phil.* (1916).—Polemical (cf. *C. A.* 8, 1535; 9, 2481; and Ishiwara, *F. Physic. Soc.* [2] 8, 106 (1915)).

The possibilities of chemical combination in the light of a new KUEMMELL. *Pharm. Ztg.* 60, 698-9 (1915).—The paper is a discussion on the work of P. John Mueller: "Die Weltraetsel im Lichte der neu u. astronomischen Forschung."

The evidence in favor of the existence of molecules. C. A. CROCHEM. *Weekblad* 12, 714-29 (1915).—An address. GEORGE

New relation derived from Planck's law. PAUL D. FOOTE. *U. Sci. Papers* No. 259, 479-82 (1915).—Any number of displacement laws from the Planck equation. This paper concerns the relation that exists between abs. temp. and the λ component of the center of gravity of the spectrum is a const. The math. treatment cannot be briefly abstracted.

Theory of emulsification. VIII. W. D. BANCROFT. *J. Phys.* (1916); cf. *C. A.* 9, 1567, 2171.—All solids show selective adsorption of vapors. The film of condensed gas shows itself in the abnormal mechanical properties of powders, in a resistance to the passage of an elec. spark between solids in the fact that 2 pieces of a broken object do not reunite when pressed together. Liquids also show selective adsorption of gases and vapors, and the gas shows itself in the behavior of fountains, jumping jets, rolling bubbles; it causes errors in the detn. of mol. wts. by the air bubble method. Adsorption of gas on the surface of Hg is not sufficient to account for the surface tension with time.

Vapor pressure of gelatin-water mixtures. KURT GERIKE. *Kolloid* (1915).—The vapor pressures of gelatin-water sols of varying concentrations were detd. by a static method. The vapor pressure is slightly higher than that of pure water and the difference increases with increase of concn., and is a measurable temperature effect. These facts together with variations in the melting point indicate that the mixt. has the character of a solution. The small decrease in vapor pressure is due to a slight soly. and the

gelatin. With water-gelatin gels the vapor pressure lowering was less the higher the temp. This seems to depend on the previous history of the gel. " β gelatin" acts the same as α except that with increasing temp. there seems to be a slight decrease in the vapor-pressure lowering. The vapor pressure of KBr soln. is increased by the addition of gelatin, that of NaCl is decreased, while LiCl and NH_4NO_3 solns. show varying effects at varying temps., probably due to adsorption of the salt or water by the gelatin. The vapor pressure of gelatin gel was detd. by the same static method, but since the concn., temp., and vapor pressure all varied the results only give the projection of a surface on a plane with temp. and vapor pressure as axes. In this case the vapor-pressure lowering of the gel over that of pure water increases with rising temp., probably because of increasing concn. To overcome this difficulty of changing concn. a method was devised for bringing the gel into equil. with air of a fixed vapor pressure, then detg. the concn. of the gel; by this method it was found that at fixed temp. the concn. of the gel varies greatly for small variations in vapor pressure if the original concn. of the gel is low. At about 70% a coagulation occurs and from that point on the water is held more firmly. Another change indicating a second coagulation occurs at 94%; beyond this the water is held very firmly. The difference between low and high concn. is marked, the former showing only slightly lower vapor pressure than that of water, the latter showing very markedly lower vapor pressure, the difference increasing with increasing concn. The change in compn. with the temp., vapor pressure remaining const., shows a regular curve with two breaks, at 39% and 90%. The rate of evapn. of water from gel does not indicate the presence of any hydrates, but rather confirms van Bemmelen's view that the water is held by adsorption. The fact that gelatin when allowed to swell in liquid water loses water on being brought into satd. air was found to be dependent upon the condition of the surface. Unsized paper shows just the opposite property, absorbing more water from satd. air after being soaked in water. If the gel be provided with a rough surface, either by covering with paper fiber or by brushing the gel surface, the effect is reversed or decreased. If paper is provided with a smooth surface by dissolving in Schweitzer's reagent and repptg., it acts like gel. Theoretically, this is explained as due to the form which liquid water pressed out from the interior of the gel assumes at the surface. If the surface is smooth the water remains in small drops with convex surface, therefore high vapor pressure, but if the surface is rough the water is evenly distributed over it, giving a flat surface of normal vapor pressure.

H. I. MATTILL.

The density and index of refraction of colloidal solutions. R. WINTGEN. Bonn. *Kolloidchem. Beihefte* 7, 251-82(1915).—On the assumption that in a dispersed system the density and the coeff. of refraction of the dispersed phase and of the dispersing agent are independent of the compn. it is shown mathematically that the density and coeff. of refraction of dispersed systems are linear functions of the concn. (g. dispersed phase in 100 cc. of the system) and that the specific vol. and product of the specific vol. and coeff. of refraction are linear functions of the percentage compn. (g. dispersed phase in 100 g. of the system). Measurements of colloidal solns. of As_2S_3 , Sb_2S_3 , silicic acid, molybdic acid, $\text{Fe}(\text{OH})_3$, and tannin confirm this conclusion. A linear interpolation formula obtained by the method of least squares gives variations between the calcd. and observed values which in no case exceed the limits of experimental error. Earlier measurements, made by other experimenters, on colloidal solns. confirm this conclusion if proper consideration is given to the question as to whether the compn. is given by weight or by volume. By the interpolation formula the calcd. density of water averages 0.99707, the product of specific volume and coeff. of refraction 1.33640. The corresponding experimental values are 0.99707 and 1.33642. The values for the dispersed phase obtained from the interpolation formula do not, however, agree

with those found for the materials in undispersed form. The sp throughout smaller in the dispersed than in the undispersed condition has been predicted on theoretical grounds by W. Gibbs, W. Ostwald, and Veimarn. Any dependence of density or refraction on degree of dispersion can be established. No comparison between the molecular refraction in colloidal and non-colloidal condition is possible, because of insufficient data on the non-colloidal materials and because anomalous effects occur in the colored solns.

Contraction produced by solution of salts. ALBERT BOLEY. *Pharm. Assoc.* 5, 38-9 (1916).—A review briefly summarizing the comments on volume changes produced by the soln. of salts. The data for six of the more common salts in various soln. strengths are presented in a table.

Diffusion of iodine in potassium iodide solutions. GRAHAM DIGGS. *J. Am. Chem. Soc.* 38, 253-9 (1916).—Solns. of 0.05 N KI, 0.25, 0.5, 1.0, 2, 3, and 4.5 N were covered with a layer of KI of the same concentration as that in the lower layer in each case, and the rate of diffusion of the iodine was determined using a 2-layer method. Fluidity detns. of the KI solns. were also made. "Increase in the concn. of KI causes, in general, an increase in the rate of diffusion of the I, and no satisfactory explanation of the influence of the KI concentration on the rate of diffusion of the iodine can be given. The results bear out the work of Van Name and others on the rate of diffusion of the iodine under the conditions of their expts."

Density and viscosity of aqueous solutions, with special reference to HNO₃. II. Viscosities. W. R. BOUSFIELD. *J. Chem. Soc.* 107, 1781-97 (1915).—A somewhat complicated gravity-flow viscosimeter is described. The vol. of liquid to be used is automatically measured out. In place of the usual observation when a meniscus crosses a mark, the liquid starts level in a very short capillary on the top of the bulb. The instrument has been used to det. the viscosity of 6 concns. of HNO₃ below N at 4, 11, and 18°C. Increasing the concn. of acid diminishes the viscosity through the change of its constitution with the solute, and to the fact that the mol. dimensions of HNO₃ and H₂O are different. The av. mol. radius of HNO₃ (including both dissociated and undissociated) is always slightly greater than that of H₂O, as shown by calcns. When the acid is completely depolymerized, the effect of increasing diln., and consequently hydration and dissociation, is to increase the av. radius of the molecules.

Vapor pressures of some saturated aqueous solutions. M. W. HUGHES. *J. Chem. Soc.* 107, 1798-1814 (1915).—The method of the Landsberger-Sakurai b. p. method. Steam was blown through the solution until a satd. soln. was obtained in equil. with the steam passing through the mixture of steam, crystals and satd. soln. was measured with and (later) with Pt resistance thermometers. A high degree of accuracy was attained with the method except in the case of very sol. salts, since it is difficult to establish equil. before all of the salt has disappeared. Data for satd. Na₂SO₄ and TiNO₃ have been taken for temps. near their b. ps., and for other salts, the results were in agreement with those obtained by Berkeby by a dynamic method. The low b. p. of TiNO₃ soln. is not due to the salt, but probably to its association.

Influence of glycerol, dextrose, alkali nitrates and sulfates, and ammonium salts on the solvent power of water. J. C. PHILIP AND A. BRAMLEY. *J. Chem. Soc.* 107, 1831-7(1915); cf. *C. A.* 9, 1572.—Expts. have been made on the distribution of EtOAc between C_6H_6 and aq. solns. of 11 compds. at 0.5, 1, 1.5 and 2 *N* concn. at 20°. The influence of the 2 nonelectrolytes was larger than expected. Na salts had the greatest effect and Li salts the least; sulfates were more efficient salting-out agents than chlorides and nitrates less so. The relative lowering of solvent power seems to depend somewhat on the substance used for measuring it. E. B. MILLARD.

Hydrates in solution. GERTRUD KORNFIELD. *Monatsh.* 36, 865-97(1915).—From f. p. detns. of C_5H_5N in aq. solns. an abnormally high mol. wt. was calcd. which increased with increasing concn. This pointed to the existence of several hydrates of pyridine which were investigated by further f. p. expts. with C_5H_5N and H_2O together in various solvents. The cryoscopic measurements in C_2H_5Br indicated the existence of a hydrate, $(C_5H_5N)_3 \cdot H_2O$. It was shown that in pure H_2O this hydrate could exist only at very small concns. of C_5H_5N , and between 7 and 17% C_5H_5N the hydrate contained 5 mols. of pyridine and 1 of H_2O . Another series of f. p. detns. with mineral salts in formamide showed the existence of hydrates of Na_2SO_4 and $CaCl_2$ even in the presence of an excess of 100 mols. of formamide. E. B. MILLARD.

Chlumsky's solution in the light of the phase rule. R. KREMMANN, F. WISCHO AND R. PAUL. *Monatsh.* 36, 911-21(1915).—The soln. is used in treating local surgical infections; it consists of a mixt. of camphor and C_6H_5OH always contg. less than 50% C_6H_5OH , and in which the latter has lost its corrosive action. It produces no irritation on sound tissues and may even be used in open wounds. No eutectic was found for the system camphor- C_6H_5OH , and at -20° the curves were falling so rapidly that none seemed probable for some distance. The system camphor- β -naphthol probably has a single eutectic at about -25°, and the system camphor-resorcinol shows the formation of a compd. between 50 and 75% camphor at about room temp. E. B. M.

Effect of dissolved substances on the velocity of crystallization of water. J. H. WALTON AND ALBERT BRANN. *J. Am. Chem. Soc.* 38, 317-30(1916); cf. *C. A.* 9, 168.—An L-shaped tube containing the soln. to be undercooled was placed in the low-temp. bath previously described and, after the tube had attained the temp. of the bath (3 or 4 min.), the soln. was inoculated and the time for the crystal growth to proceed one meter was detd. with a stop-watch. Detns. at -9.1° on the same soln. were reproducible to within a few tenths of a sec. Solns. of 0.1 *M* concn. of 18 inorg. substances and 12 org. substances were studied at -9.1°, together with solns. of 8 substances of high mol. wt. at 0.02 *M*. Expts. were also made with colloidal substances and at other temps. The dissolved substance decreases the velocity of crystn. in each of the 45 cases studied, but solns. of different substances at the same concn. show different effects. For substances with more than 8 atoms to the mol. there was a rough parallelism between this number and the inhibition of crystn., but for compds. with less than 8 atoms the retarding effect seemed to be a sp. property. Marc's theory of adsorption inhibition is untenable, since sugars, which are not much adsorbed, produce a marked effect on the velocity of crystn. Gelatin, colloidal $Fe(OH)_3$, and dyes decrease the velocity of crystn. The stability of the soln. toward spontaneous crystn. varies with the solute, 0.1 *M* HCl being exceptionally stable. Solns. of 0.00125 *M* brucine sulfate do not affect the velocity of crystn. E. B. MILLARD.

Anisotropic aqueous solution. HAKAN SANDQVIST. *Ber.* 48, 2054-5(1915).—Solns. of 10-bromophenanthrene-3- or -6-sulfonic acid in H_2O show a clouding at a temp. which is definite for any single concn. and is the same whether measured with rising or falling temp. The mol. wt. detd. from f. p. is about 1300. No supersatn.

is connected with the clouding of the soln., and no marked effect accompanied the phases. It was shown in an ultramicroscope that the soln. was a magnification of 300 the liquid showed the rounded drops and structural liquid, and there was a color play when the analyzer was rotated. The properties and the existence of a critical point establish the presence of in the soln. Measurements of the elec. cond. and viscosity are in progress.

E. J.

Velocity of ionic reactions. GERTRUD KORNFIELD. *Monatsh.* 36.—From measurements of the cond. of solns. by the method of Benec (1406), in which it was possible to det. the cond. of a mixt. 0.004 sec. was found that the reactions were complete as soon as measurements were made. The reactions studied were the neutralization of C_4H_5N with C_4H_5OH with H_2O . No data are given.

E. J.

Indirect determination of the velocity of hydrolysis by the polarimeter. J. C. CROCKER. *J. Chem. Soc.* 107, 1762-3 (1915).—The method is the velocity of hydrolysis of *N* formamide by *N* acid in the presence of sugar. The hydrolyst acted simultaneously on the formamide and the sugar, and the change of the rotation the extent to which the main reaction had proceeded. If the hydrolyst is gradually used up in the principal reaction is not affected by the secondary reaction, the change of this concn. is deduced from the speed of the secondary reaction. The rotation of sugar by the presence of formamide. In the expts. here given the velocity of the reactions were practically equal. Both of them increased somewhat with 13.8 to about 14.3. The principle is applicable to any reaction in which a reaction changes its concn. in the main reaction and is able to act as a catalyst in a secondary reaction proceeding in the same soln.

E. J.

General equations for the neutralization of dibasic acids, and their application to the acidity of dilute carbonate solutions. E. B. R. PRIDEAUX. *Proc. Roy. Soc. (A)* 91, 335-43 (1915).—Mathematical discussion, first of the general application to solns. of CO_2 and to dil. carbonate solns. No new data are given.

Dynamics and kinetics. ROBERT KREMAN. *Fortschritte Chem.* 11 (1915).—Progress in this field during the second half of the year 1914 under the following heads: homogeneous equilibria, heterogeneous equilibria.

Thermochemistry. H. VON WARTENBURG. *Fortschritte Chem.* 11.—A review for the period April, 1914, to April, 1915. The subject is under the following heads: temp. measurement, sp. heat, heat of reaction, at high temps.

Electrical theory. GEORGE GIBLHOF AND HANS RUCK. *Fortschritte Chem.* 11, 43-51, 77-88 (1915).—A review of progress for the period Oct., 1913, to

The velocities of the photoelectrons emitted in the normal and the selective effects. A. L. HUGHES. Rice Inst., Houston. *Phil. Mag.* 3.—In spite of the 16-fold greater photoelectric effect in the "selective" effect, than in the normal, there is only a slight difference in the number of the two cases, this being due either to slightly smaller velocity of the photoelectrons or to their being emitted relatively more in a direction normal to the surface. This indicates that there is no fundamental difference between the two

G.

Reflection of slow moving electrons by copper. A. W. HULL. *Phys. Rev.* 7, 1-17(1916).—The electron reflection from a Cu surface roughened by prolonged heating at 350° *in vacuo* is, like that of electrolytic Ag, very small, being only 10% for electrons having a velocity of 0.4 v. This is due to the extreme ultramicroscopic roughness of these surfaces, which should make excellent "black bodies" for receiving electron currents. The scattering of a beam of slowly moving electrons is due to deflection by strong elec. field. Delta rays have been produced by Hg ions which have fallen through only 12.4 v. The energy of the fastest of these rays is approx. the same as that of the ions, suggesting that the energy exchanges between ion and electron are governed by quantum relations.

E. B. MILLARD.

Einstein's photoelectric equation and contact electromotive force. R. A. MILLIKAN. *Phys. Rev.* 7, 18-32(1916).—The following tests of Einstein's equation have been considered and, except the last, subjected to exptl. proof: the existence of a definite and exactly determinable max. energy of emission of corpuscles under the influence of a given wave length; the exact appearance of Planck's h in the slope of the potential-frequency line; and the agreement of the long wave limit with the intercept of the p. d., ν line, when the latter has been displaced by the amt. of the contact e. m. f. Contact e. m. f.'s are accurately given by $(h/e)(\nu_0 - \nu_0') - (V_0 - V_0')$ and are independent of temp.

E. B. MILLARD.

Electrostatic basis for the law of mass action in electrolytic solutions. R. A. LATTEY. *Chem. News* 111, 135-6(1915).—A math. derivation of the law of mass action from considerations of the forces exerted by a charged sphere of given radius when introduced into a soln. contg. positive and negative ions. The product of the positive and negative ion concns., $C^+ \cdot C^-$, was a const. depending on the concn. of the soln.

E. B. MILLARD.

Long direct current arcs. WALTER GROTRIAN. *Ann. Physik* 47, 141-96(1915); *Chem. Zentr.* 1915, II, 60.—The relations between current strength and voltage have been measured for very long arcs between various electrodes in air, N, O, CO₂, H and H₂O vapor. The atm. in which the arc is formed, but not the materials of the electrode, may exert an influence on the characteristics of the arc. Detns. in the air arc showed that the potential drop along the arc was the same in all parts of the light column and, entirely independent of the arc length, increased along a hyperbola with increasing current. The cathode drop was about 20 v., independent of the current, arc length and (nearly) of the material of the electrodes. The anode fall was independent of the length of arc, but changed from 130 to 30 v. with change of current from 0.1 to 3 amp. and was influenced by the compn. of the electrodes. By cross-measurements in the CO₂ arc it was shown that the c. d. increased linearly with the field strength. A theory of the processes in the arc based on impact ionization by electrons is given.

E. B. MILLARD.

Anodic relations of passive iron, with notes on polarization potentials as influenced by gas pressures. H. G. BYERS AND S. C. LANGDON. *J. Am. Chem. Soc.* 38, 362-74 (1916); cf. *C. A.* 8, 3738.—Extension of the previous work to electromotive behavior of polarized passive electrodes. A calomel cell has been made which contains no air space and is suitable for pressure work. On application of gaseous pressures, anodes of passive Fe, or any other metal anode from which O was being evolved, became more electropositive and cathodes more electronegative. The change was a function of the mechanical pressure and not of the degree of satn. of the electrolyte with dissolved gas. From the variations of polarizing current and anodic potential during the process of passivation curves were constructed which indicate that passivation is here a 2-process operation. There is no general explanation of passivity, each case requiring an explanation according to conditions.

E. B. MILLARD.

Potentials at the junction of salt solutions. D. A. MACINNES. *Proc. Nat. Acad. Sci.* 1, 526-30(1915); see C. A. 9, 2834. E. B. MILLARD.

Double salts in standard cells. G. F. LIPSCOMB AND G. A. HULETT. *J. Phys. Chem.* 20, 75-82(1916).—Solns. of a K salt of varying concn. were rotated with excess of the corresponding Zn or Cd salt in tubes for several days after equil. seemed to be established. The diagram of the 3-component system K_2SO_4 , $ZnSO_4$, H_2O had 3 branches corresponding to K_2SO_4 , $ZnSO_4 \cdot K_2SO_4 \cdot 6H_2O$, and $ZnSO_4 \cdot 7H_2O$; the 3-component system $ZnCl_2$, KCl , H_2O also showed the existence of a double salt. Detns. of e. m. f.'s of cells contg. double salts were made as follows: $Zn \text{ amalgam} | (K_2SO_4 \cdot ZnSO_4 \cdot 6H_2O), Hg_2SO_4 | Hg, v \text{ (at } 25^\circ) = 1.46965$; $Zn \text{ amalgam} | \left\{ \begin{matrix} K_2SO_4 \cdot ZnSO_4 \cdot 6H_2O \\ K_2SO_4 \end{matrix} \right\}, Hg_2SO_4 | Hg, v \text{ at } 25^\circ = 1.48680$. Satd. solns. of the double salt alone or K_2SO_4 seemed to hydrolyze the depolarizer, but the difficulty of hydrolysis is overcome in the combination $Zn \text{ amalgam} | \left\{ \begin{matrix} K_2SO_4 \cdot ZnSO_4 \cdot 6H_2O \\ ZnSO_4 \cdot 7H_2O \end{matrix} \right\}, Hg_2SO_4 | Hg$, and the e. m. f. at 25° was 1.41976 with a negative temp. coeff. of 0.00133. Reproducible cells were obtained with the combination $Cd \text{ amalgam} | (2KCl \cdot CdCl_2 \cdot 6H_2O), Hg_2Cl_2 | Hg$, with an e. m. f. at 25° of 0.70505 and a temp. coeff. at 18° of +0.00015. A cell was made with the double salt $2KCl \cdot ZnCl_2 \cdot 6H_2O$, but the salt was unstable when brought into soln.

E. B. MILLARD.

Electromotive forces. W. D. BANCROFT. *J. Phys. Chem.* 20, 64-74(1916); *Trans. Am. Electrochem. Soc.* 28, 357-70(1916).—The treatment of Nernst is adapted to historical development, but is not a logical one for teaching purposes. It is suggested to develop all e. m. f. equations from the van't Hoff formula $E = (RT/nF) \log K \Sigma p_i / \Sigma P_i$, where Σp_i refers to the substances which are consumed during the reaction and ΣP_i to the substances which are formed. Five types of cells are recognized, all of which are to be treated in the same general manner. E. B. MILLARD.

Studies in conductivity. III. Further studies of the behavior of the alkali metal formates in (anhydrous) formic acid. H. I. SCHLESINGER AND CLYDE COLEMAN. *J. Am. Chem. Soc.* 38, 271-80(1916); cf. C. A. 8, 3259.—Formates are highly ionized in soln. in $HCOOH$ and obey the mass law if the degree of dissociation is calcd. from the cond. ratio without taking into account the viscosity effect; however, they do not obey this law if the degree of dissociation is calcd. with a viscosity correction. In most details the exptl. method was the same as that formerly used, but a viscosimeter such as that of Washburn and Williams (C. A. 7, 2873) was used. Conds. have been measured for several concns. at 18 and 25° of the formates of Li, Na, K, Rb and Cs, together with viscosities and ds. for these solns., and the values of the equil. consts. have been calcd. from the data obtained. The equil. const. increases with increase in at. wt. of the cation, as does the cond. at infinite diln., though in this latter there is a marked exception in the case of Cs. The former work has been repeated, and found to be correct. Again no constancy of the equil. expression was found if the degree of dissociation was calcd. with the use of a viscosity correction, and this is thought to prove that the true degree of dissociation may be calcd. from the cond. ratio, since it is so improbable that the agreement could be due to a cancellation of errors for so many substances and at 2 different temps. E. B. MILLARD.

Photochemistry. M. BLASCHKE. *Fortschritte Chem.* 11, 147-69(1915).—Progress in this field is reviewed for the second half of the year 1914. Theoretical investigations, optics of photochemistry, fluorescence, phosphorescence, luminescence, photoelec. phenomena, photochem. reactions and phototropy are covered. L. H. A.

The production of light by the recombination of ions. C. D. CHILD. *Colgate Univ. Phil. Mag.* 31, 139-43(1916).—A restatement of a former suggestion (C. A. 8,

2522) that the light from the luminous vapors in the arc is due to recombining ions, and a criticism of the theory of Strutt (*C. A.* 9, 550) that the luminosity persists in the positive ions.

G. L. WENDT.

Phosphorescence. K. SCHERINGA. Alkmaar. *Chem. Weekblad* 12, 1106-9(1915).—A short discussion of phosphorescence and allied phenomena, in which thermoluminescence and fluorescence are ascribed primarily to the effect of impurities. *E. g.*, incident light sets up vibratory disturbances in a substance; the natural period of the impurities differs from that of the mass of the substance, and the resulting collisions are the cause of the luminescence. Phosphorescence is ascribed to a substance having taken up, under, *e. g.*, the influence of high temp., a structure peculiarly favorable to certain atomic or molecular vibrations which emit light; on cooling the structure persists, and the substance prolongs incident vibrations by a resonance-like process.

GEORGE W. MOREY.

E. B. MILLARD.

Absorption spectra of the blue solutions of sodium and magnesium in liquid ammonia. G. E. GIBSON AND W. L. ARGO. *Phys. Rev.* 7, 33-48(1916).—The absorption spectrum was measured with a spectrophotometer of the Grünbaum-Martens type (*Ann. Physik* 12, 984(1903)) in a quartz cell capable of holding NH_3 at room temp. A soln. of Mg and a soln. of Na of the same intensity of color at -33.5° were found to have the same absorption spectrum. This is strong evidence that the coloring principle is the same in both cases. Approx. measurements of the concn. of Na solns. make it probable that Beers' law holds for the total dissolved Na. The evidence is in favor of the assumption that the absorption is due to unsolvated electrons, but the measurements cannot be interpreted quant. in terms of Drude's theory of metallic dispersion.

E. B. MILLARD.

Construction of sensitive photoelectric cells. JAKOB KUNZ AND JOEL STEBBINS. *Phys. Rev.* 7, 62-5(1916).—A thin mirror of alkali metal was distd. into the cell while the Ag mirror was cooled with ice, and an atm. of H was then introduced. Efforts to use C_2H_2 , NH_3 or C_2H_4 were not successful. The best results were obtained with Rb and an atm. of Ne. These cells show a very small dark current; if it exists at all it can be compensated by the application of a small potential between the electrodes. Na cells were difficult to make. Cs was liquid at 28° and could not be used directly. A solid Cs amalgam was of weak sensitiveness. The cells are applied to stellar photometry.

E. B. MILLARD.

The arc and spark spectrum of silver referred to the international normals. JOSEPH FRINGS. *Z. wiss. Phot.* 15, 165-82(1915).—The arc and spark spectra of Ag were measured in reference to Fe normals from $\lambda 5670$ to 2220 . The results are tabulated with intensities and measurements by other investigators. The lines of the impurities are listed and many of the Ag lines are correlated in series.

PAUL D. FOOTE.

Theory of the Zeeman effect in relation to lines of force at an angle. W. VOIGT. *Ann. Physik* 47, 245-69(1915); *Chem. Zentr.* 1915, II, 64; cf. *C. A.* 9, 13, 1002.—V. has developed the theory of the Zeeman effect on the assumption that the magnetic sepn. of the characteristic absorption lines of the substance under consideration is completely general. A complete numerical calcn. has been carried through for the case in which an absorption line has been decomposed into a triplet by the magnetic field.

The conception of the Reimann surface has been used in the calcn., v to brief review.

Influence of catalyzer poisons on the photoelectric sensibili
KRÜGER AND E. TAEGER. *Z. Elektrochem.* 21, 562-9(1916).—A Do was used to measure the photoelec. sensibility to light from a qua plates, a special app. being used. The photoelec. sensibility (P. E. S) typical catalyzer poisons such as CO, HCN and H₂S, especially the la with H₂S the P. E. S. was not wholly restored after repeated admissio tion again. Perhaps a film of a Pt sulfide was formed, as has bee cases of poison. It was uncertain whether a film formed from the o In this case the P. E. S. was rapidly restored and there was a kind usual in such cases, and which is in agreement with the smallness o vacua. A part of the effect may be due to penetration of the g film; this makes it difficult to get reproducible results. Bomba with N was without effect, showing the electrochem. indifferenc Bombardment with CO₂ caused a small increase in the P. E. S.; NH₃ It appears that the easy emission of electrons (which corresponds is closely connected with some catalytic process which cannot be further knowledge of the catalytic process itself.

Thermomagnetic properties of various compounds and the W
netons. KÔTARÔ HONDA AND TÔRAJIRO ISHIWARA. *Sci. Reports* 4, 215-60(1915); cf. *C. A.* 8, 618, 1385, 2648, 3751.—The same exp magnetic susceptibilities has been used as in the previous papers. compds., mostly of Fe, Ni and Co, for several temps. are reported, an in tables and plates. The susceptibility of paramagnetic compds. ha value, which is different from that which can be obtained from of the constituents by the additive law. Curie's law for param is only applicable to a very limited number of substances. For paramagnetic substances the hyperbolic law of Onnes and Perrier b approximately, for the whole interval of temp. in which the substa gle phase. Any abrupt change of susceptibility at a certain ter change in a certain range of temps., is in many cases a consequen chem. change. For the diamagnetic substances here investigated is const. for all temps. so long as the substance exists in the same state is accompanied by change of susceptibility. Water of crystn. ceptibility in different amts. for different compds. Even in the : mols. of H₂O of crystn. which escape from the crystals at different ent effects on the susceptibility. The thermomagnetic investigat affords a good means of detecting changes of structure at high t

Registration of rapidly changing pressures. W. NERNST. *Abh. Wissenschaften* 1915, 896-901.—A membrane manometer s by Pier (*C. A.* 3, 2898) and used by Bjerrum (*C. A.* 6, 3048) in th O₂ shows rapid vibrations which sometimes interfere with the mea them impossible. This paper is a theoretical math. discussion of vibrations.

Molecular weight determination of some vegetable oils (Bac viscosity (HOLGATE) 21. Unstable states in arc and glow (CAY).

3. RADIOACTIVITY.

WILLIAM H. ROSS.

Recent progress in the physics of the Röntgen ray. A. SOMMERFELD. München. *Naturwissenschaften* 4, 1-8, 13-8(1916).—This review is classified under several headings such as "Polarization of the X-ray," "Crystals used as diffraction gratings," etc.

C. G. F.

Transformation of chemical elements. II. W. P. JORISSEN AND J. A. VOLLGRAFF. Leiden. *Z. physik. Chem.* 90, 557-60(1915); cf. *C. A.* 9, 886.—It is pointed out that, if Tl in Bi is produced by spontaneous transformation, not only must Tl always be present in Bi, but also in Bi and Bi minerals there must be a const. ratio between the quantities of the 2 elements.

H. JERMAIN CREIGHTON.

Density of lead from radioactive minerals. T. W. RICHARDS AND CHARLES WADSWORTH. *J. Am. Chem. Soc.* 38, 221-7(1916).—Pb from Australian radioactive minerals was recrystd. as nitrate from hot H₂O with the addition of HNO₃, or pptd. and recrystd. as PbCl₂. The d. of ordinary Pb (at. wt. 207.2) was detd. in a modified Ostwald-Sprengle pycnometer adapted for use with solids, and was found to be (reduced to vacuum standard) 11.337 at 19.94°. At the same temp. the d. of radioactive Pb (at. wt. 206.3) was found to be 11.288. Continued fractionation of the material produced no change in this low d., and it could not have been due to any irregularity in prepg. the metal, since the samples of both kinds of Pb were made in the same way. The difference in d. almost exactly parallels the difference in at. wt., so that the at. vol. for radioactive Pb is almost exactly equal to that of ordinary Pb, the figures being in each case very nearly 18.28.

E. B. MILLARD.

Interaction of hydrogen and chlorine under the influence of alpha particles. HUGH S. TAYLOR. *J. Am. Chem. Soc.* 38, 280-5(1916); cf. *C. A.* 9, 412.—The 4 series of expts. previously reported are recalcd. to remove an error in the original, and a 5th series is added. No change was made in the exptl. method. Details are given of the correction for the incomplete absorption of the α -particles by the gas. Emanation from 10 mg. RaBr₂, under certain assumptions, would cause the radiation of 4×10^{18} ions per sec. into the reaction mixt., and in the most favorable case 7×10^{16} mols. of Cl per sec. were converted into HCl. That is, 4000 mols. of gas react for each pair of ions entering the gas, which as regards light sensitivity was considerably inferior to that employed by Bodenstein and Dux (*C. A.* 8, 452). The original theory of Bodenstein explaining the reaction under the influence of light is applicable to the reaction under α -particles.

E. B. MILLARD.

The effect of magnetization on the opacity of iron to Röntgen rays. A. H. FORMAN. *Phys. Rev.* [2] 7, 119-24(1916).—An increase of 5 per 1000 in the opacity to X-rays of a thin sheet of Fe, magnetized in the direction of the rays by a field of 3500 gauss, was detected by a differential method. More complete orientation of the mols., in a stronger field, should give a larger effect. Since no such effect was detected when the magnetization was perpendicular to the path of the X-rays (*C. A.* 8, 2108), the plane of max. absorption of the rays is the plane of the electronic orbits which make up the elementary magnets, and it shows its max. effect when it is parallel to the direction of the cathode ray stream, *i. e.*, perpendicular to the direction of the X-rays. It is suggested that the failure of X-rays to ionize all the mols. of a gas through which they pass is due to the mol. having only one plane in which it can absorb sufficient energy for ionization.

G. L. WENDT.

The radioactive deposits from the atmosphere on an uncharged wire. S. J. M. ALLEN. Univ. Cincinnati. *Phys. Rev.* [2] 7, 133-8(1916).—Radioactive deposits of the Ra series, with periods varying from 8 to 50 minutes, were collected on a long

uncharged wire exposed to a smoky atm. No Th was detected. The smoke nuclei act as carriers, for it was found that the activity was roughly proportional to the amt. of soot deposited; that a "smoke fog" or a rainstorm was followed by a great decrease in collected activity; that winds from the smoky quarter increased the activity; and that the annual max. in November corresponds with the max. of smoke in the air.

G. L. WENDT.

Radioactive fluctuations accompanying the use of unsaturated currents. A. ERNST. Tübingen. *Ann. Physik* 48, 877-906(1915).—Schweidler's percentage fluctuations in the ionization current due to a radioactive substance should equal the inverse sq. root of the number of atoms disintegrating per sec., and should be independent of the voltage used. Kohlrausch found a decrease in the percentage fluctuation with decreasing degree of satn. of the current. This E. now confirms over a wider range and shows that the fluctuation is const. as long as the ionization current obeys Ohm's law. Campbell's theory (*C. A.* 5, 3004) explains the decrease in the fluctuations by a decrease in the capacity of the electrometer system accompanying an increase in the resistance of the ionization chamber. The explanation is accepted, and the true fluctuations are held to be independent of the voltage.

G. L. WENDT.

Occupational injuries due to radium (ORDWAY) 11H. Structure models according to W. H. and W. L. Bragg (M'CGG) 1.

Tungsten anticathodes for Röntgen tubes. O. A. SIMPSON. U. S., 1,167,532. Jan. 11. W powder is pressed and fused into an integral plate. A hole is made in the plate through which a W rod is inserted with its end projecting beyond the surface of the plate. The rod and plate are fused together and chilled while the surface of the plate is curved under the surface tension of the metal.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Inorganic electrochemistry. K. ARNDT. *Fortschritte Chem.* 11, 1-10, 1915 —A review of progress in this field during 1914. (*C. A.* 10, 4271). L. H. A

The thermal insulation of high-temperature equipment. P. A. BOWEN. *Trans. Am. Electrochem. Soc.* 28, 24-60 1916.—While an air space is an effective insulator at low temps., as in refrigeration, it is not so at high temps., for there the loss by radiation is large, being proportional to the 4th power of the absolute temp. It is much better to use a solid wall, which may be backed with some insulating material, or may contain a layer of insulating material. See *C. A.* 9, 25-7. SHERMAN EASTMAN.

Operating characteristics of lead storage batteries. J. H. TRACY. *Eng. J.* 13, 17-20, 1916.—High rates of discharge are in no way detrimental to modern lead battery plates. Data are given, showing variation in available capacity of a battery when discharged continuously at a constant rate. If a battery be discharged intermittently during periods of rest, the acid in the pores of the plates is being removed by diffusion, and an operative advantage may be taken of this. A general rule for determining the max. permissible rate of charging a battery is: The charging rate in amp. must never exceed the amp.-hrs. out of the battery. Curves are given which show that the max. charging rates are not functions of the size of the battery or its relative rate of discharge. A battery is fully charged only when all the sulfate has been driven out of the plates into the electrolyte; this is most easily indicated by the ϵ of the electrolyte; data and curves of charging rates are given. E. W. BUCHHEIM

Charging Edison storage batteries. E. J. ROSS, JR. *Elec. J.* 13, 25-7(1916).—The "constant current" and "tapering current" methods of charging are described and the chem. reactions which occur during discharge and recharge are given. Either method of charging is satisfactory if properly used. In the "tapering current" method the condition of charge can be accurately detd. by the ammeter reading.

E. W. BOUGHTON.

Cells with aluminium electrodes (aluminium rectifiers). ELENA FREDA. Rome. *Nuovo cimento* 10, 169-222(1915).—Metals other than Al, in certain electrolytes, behave analogously. Examples are Mg, V, Nb, Ta, Zn, Cd, Bi, Sb. If a current of electricity passes through certain electrolytes having Al as anode, the intensity of the current at first decreases rapidly, then more slowly till it becomes practically a const. This same const. is also soon reached if the intensity of the current is increased to begin with or if the circuit is opened and then closed again. If the Al electrode so formed is made cathode, an intense current will instantly pass through the cell. The formation of the Al electrode may also take place, more slowly, with an a. c. If the semisoidal e. m. f. is of period T , there is a continual component of the current obtained, towards the Al, according to the formula $i_s = (1/T) \times \int_0^T idt$. If the circuit is closed, and an e. m. f. continues of value V , less than the tension of formation but of the same sign, the p. d. between Al and electrolyte takes a value practically equal to V . If now, the Al and the other electrode are short-circuited, a quantity of electricity Q passes through the short circuit, proportional to V . The ratio $c = Q/V$ depends on the tension of formation. The cell accordingly behaves like an imperfect condenser. The most complete explanation of the behavior of the cell agrees with Schulze's theory, according to which a layer of non-porous oxide forms on the Al, then at different spots layers of O and of porous oxide. F. has detd. that inverse currents do not uniformly reduce the layer of O that covers the formed electrode of Al, but only at some points, and this with small quantities of electricity. F. detd. the conditions which were necessary to give the best valve effects (rectification). Polarization has no noteworthy influence upon the characteristic behavior of the oscillatory discharge which discharge has the same characteristics even when the electrodes of the cell are very small. When Al functions initially as a + electrode, there are no appreciable phenomena of reduction during the oscillatory discharge, from which F., studying the discharge of the cell through a large resistance, deduces the existence of a limiting inverse e. m. f. This is true even when there is substituted for the Al other metals that have an analogous behavior with respect to a d. c., but which, towards an a. c., do not allow of any inferences as to the existence of a limiting inverse e. m. f., since the — half wave of such currents produces reduction phenomena with these electrodes. These ideas were confirmed on substituting Zn for Al. A study was made of the properties of formed Al electrodes in Hg. F. concluded (1) that the electrolytic cond., met with by Corbino and Maresca (*Nuovo cimento* 1906, 29), through the layer of oxide that covers a formed Al electrode, is probably a common property of thin solid layers that are deposited during the formation of metal electrodes having a similar behavior to that of Al in their proper electrolytes; (2) a formed electrode, immersed in Hg, can be made to serve as a coherer. Cf. Schulze, *C. A.* 8, 2652.

S. LÆVY.

Nickel plating aluminium. J. CANAC. *J. Ind. Eng. Chem.* 8, 190(1916); cf. *C. A.* 8, 2529; 9, 1169, 1583.—A method for obtaining a firmly adhering coat is briefly described. The Al is first cleaned in boiling KOH soln., next in milk of lime and then in KCN bath for a short time. Finally the Al is dipped into a bath of FeCl_2 soln. (*C. A.* 9, 292). After each operation the object is washed in clean H_2O . The plating bath consists of 50 g. NiCl_2 + 20 g. H_2BO_3 in 1 l. H_2O . C. d. = 1 amp. per sq. dm.; v. = 2.5.

C. G. F.

Electrolysis and its mitigation. E. B. ROSA AND B. MCCOLLOM. Bur. Standards, *Tech. Paper* 52, 143 pp. (1915).—General considerations regarding electrolysis, methods of mitigation applicable to pipes and to railway negative return, and regulations regarding electrolysis mitigation are included. It is stated that the application of paints, wrappings, etc., to positive areas is of no value and may do harm, but on negative areas such application may be used to afford protection of an auxiliary character against corrosion. Protection by chem. means or by cement coatings is only of a temporary nature. Cathodic protection is complicated and expensive and is practically worthless. Placing pipes as far as possible from railway tracks affords a certain measure of protection. Pipe drainage is sometimes useful (for instance in isolated pipe systems without insulating joints), but should be used with proper restriction and with due precaution. The problem is more serious in the U. S. than in those European countries which have applied government regulation. Electrolytic damage to concrete structures is to be feared only where voltage conditions are exceptionally severe, or, in the case of comparatively low voltage, when salt has been added to the concrete. The principal reliance for the mitigation of electrolysis should be on proper construction and maintenance of the railway return circuit. Insulating joints in pipes are useful when new pipes are being laid. When pipe drainage is used the drainage should be through the medium of insulated feeder systems, so adjusted as to take the minimum possible current from the pipes at all points. For railways the following are essential: adequate maintenance of track bonding, the use of a proper number and location of power houses and sub-stations, and, in some cases, the use of insulated negative feeders for return of current. The three-wire system has proved effective in relieving electrolysis. Experience indicates that limitation of voltage drop is necessary for a satisfactory solution of the problem. For defining such limitation an all-day average is recommended and the use of the zone system or similar plan. Under most conditions over-all voltage in railway tracks should be limited to about 2-4 volts, and the potential gradients to 0.3-0.4 volt per 1000 ft. (all-day averages). For detn. of voltage drops potential wires should be installed. Regulations should apply not only to railways but should define the responsibilities of owners of underground utilities.

E. W. BOUGHTON.

Unstable states in arc and glow. W. G. CADY. Wesleyan Univ. *Trans. Am. Electrochem. Soc.* 29 (advance copy); *Mct. Chem. Eng.* 13, 866-9 (1915).—This is a very clear exposition of the various forms of discharge through gases. C. carried out a large number of expts.; the results are best summarized in the accompanying fig. The curve OACG shows qualitatively the relation between current and voltage in the discharge

between 2 fixed electrodes. The nature and pressure of the surrounding gas are supposed to be constant, except as modified by conditions at the electrodes themselves. In the fig. *OA* is the saturation current; this current is carried by the few free ions that are always present. *AB* is the glow discharge proper in which the rate of ionization is so great that the voltage across the gap begins to drop. As *B* is approached the cathode rapidly becomes incandescent and the emission of electrons commences. The discharge quickly resolves itself into an arc and the current is carried chiefly by the vapor from the cathode. The portion *BC* of the curve cannot be observed. Over *CD* the discharge is an arc as far as the cathode is concerned, but since less energy is expended at the anode, at the latter a glow discharge may still be had. The positive base of the discharge is

still diffuse and faintly luminous. This is the first stage of the arc. With increasing current the anode is brought to the b. p. This causes a decrease in the anode drop and a further increase in the cond. of the gas, so that the portion *DF* is quickly passed over. *FG* is then a full arc or second stage arc. Cady obtained a glow discharge between C electrodes at 460 v. in N gas at reduced pressure. With pure Ag electrodes and currents as high as 1.3 amp. the discharge is still a glow though the molten metal is white hot and vaporizes rapidly. This is important evidence that incandescence and vaporization of the cathode are not enough of themselves to cause the formation of an arc. The admission of a little O caused an arc to form at once (between the Ag electrodes). In the Fe arc in free air the discharge normally takes place between globules of molten oxide. The bright spot at the positive end of the arc is in rapid rotation, describing a minute circle (cf. *C. A.* 8, 455). The concluding paragraphs of the paper are devoted to the singing arc. C. G. F.

Flushing storage batteries. ANON. *Elec. Rev. West. Elec.* 68, 245 (1916).—A method of flushing is shown diagrammatically. C. G. F.

The production and properties of electrolytic copper (WILBOURN) 9. The application of electricity to the heating of metals (BISHOP) 9.

Ductile alloys of high melting point. H. KAISER. U. S., 1,167,827, Jan. 11. The addition of about 0.05% of Pt or other metal of the Pt group to an alloy of W with 1% Th increases the toughness and ductility of the alloy. The product is suited for making filaments for incandescent lamps. Various alloys of Cr, V, Cb, Ta, Os, Ru, Zr, Th and W may be improved by the addition of very small amts. of Pt or a similar metal.

Storage battery. T. A. EDISON. U. S., 1,167,485, Jan. 11. A positive electrode for alk. storage batteries is formed of a perforated tubular receptacle packed with Ce oxide and flake Ni in alternate layers. Fe or Fe oxides are used in the negative electrodes.

Nickel hydroxide. T. A. EDISON. U. S., 1,167,484, Jan. 11. Ni(OH)_2 for use in alk. storage batteries is produced by pptn. from a soln. of NiSO_4 or other sol. Ni salt, by the addition of a considerable excess of alk. hydroxide. The pulpy ppt. is evapd. to dryness together with the excess of alkali and then washed and dried to purify it. The use of excess alkali in this manner serves to increase the porosity of the ppt.

Primary electric battery. W. E. HOLLAND. U. S., 1,167,499, Jan. 11. Structural features of Zn electrodes.

Electrolytic cell. L. E. PORTER. U. S., 1,167,594, Jan. 11. The pat. covers structural features of a cell especially adapted for extg. metals directly from ores. Cf. *C. A.* 9, 1434.

Graphite plate cathode for electrolytic cells. F. McDONALD. U. S., 1,167,705, Jan. 11. Structural features of diaphragm cells for electrolysis of NaCl, etc.

Amalgamating ores. L. ST. D. ROYLANCE. U. S., 1,168,678, Jan. 18. Ores of Au and other metals are simultaneously subjected to electrolysis in a NaCl soln. and scoured and then amalgamated.

Determining amount of suspended matter in gases. W. A. SCHMIDT. U. S., 1,168,227, Jan. 1. A current of flue gas or other gases carrying suspended solids is passed between electrodes between which a silent discharge of high potential is maintained and the amt. of discharge is measured to indicate indirectly the amt. of solids carried by the gas.

Experimental inorganic chemistry. F. SOMMER. *Fortschritte Chem.* 11, 51-63 (1915); cf. *C. A.* 9, 1284.—A review of progress for the second half of the year 1913.

L. H. A.

Hydrolysis of alkali salts; and reaction to litmus. F. FICHTER. *Naturforsch. Ges. Basel* June 16, 1915; *J. Soc. Chem. Ind.* 34, 1008.—The view that alkalinity of solns. of alk. salts of weak acids increases with increasing diln. is not correct, for although the degree of hydrolysis increases with the diln., the rate of increase is lower, so that the abs. concn. of OH ions decreases with increasing diln., until finally alkalinity can no longer be detected with sensitive litmus paper. With Na_2CO_3 soln. alkalinity can be detected down to $N/512$, with KCN down to $N/256$, with NaNO_3 to $N/8$, with $\text{C}_6\text{H}_5\text{COONa}$ to $N/4$, and with $\text{KNaC}_4\text{H}_4\text{O}_6$ not distinctly even at $N/2$. Statements as to the reaction to litmus paper of salts of weak acids should always be accompanied by precise data as to the concn. of the soln.

L. W. RIGGS.

Polyiodides. III. System cuprous iodide-iodine. R. KREMANN AND V. BORJANOVICS. *Monatsh.* 36, 923-7 (1915); cf. *C. A.* 7, 737, 945.—The existence of polyiodides in soln. is not to be expected, since CuI_2 decomposes spontaneously into CuI and I . Mixts. of CuI and I of various compns. were heated together at 200 to 240° for several hrs., and the cooling curves followed. The breaks in the cooling curves, when plotted against % CuI , gave a smooth straight line, whose projection ended at the m. p. of CuI , and showed no indication of the existence of any compd. contg. more I than CuI . Further expts. were carried out in which the vapor pressures of mixts. of CuI with various amts. of I were detd., but the vapor pressure was in every case identical with that of pure I , and again showed no indication of the existence of a compd. contg. more I than CuI .

E. B. MILLARD.

The reactions between solutions of sodium silicate and aluminium sulfate or chloride. W. GORRWALD. *Dissertation Erlangen* 1913, 43 pp.; *Neues Jahrb. Min. Geol.* 1915, II, Ref. 51-3.—When Na silicate solns. react with $\text{Al}_2(\text{SO}_4)_3$ or AlCl_3 , a gelatinous, finely flocculated ppt. forms. In the presence of Cl ions this ppt. settles more rapidly than in that of SO_4 ions, and can also be more easily filtered. Beside Al silicate, the ppt. contains alkali compds. Silicic acid and Al compds. were also found in the filtrate, in addition to the alkali sulfate or chloride. At first the reaction of the ppts. is weakly acid, but soon becomes neutral. A rise in temp. of the solns. is observable during the reaction. The reaction is rapid at first, but the velocity soon decreases. Even after standing several months a complete quant. change does not occur, but the reaction seems to have reached a state of equil. The filtrates hold only very little Al . In general, the influence of the specific anion upon the mechanism of the reaction is small. A comparison of the analyses of the gels obtained with $\text{Al}_2(\text{SO}_4)_3$ with those obtained by using the chloride showed the ratios: SO_4 gels, alkali: $\text{SiO}_2 = 1:2$; Cl gels, alkali: $\text{SiO}_2 = 1:1$.

E. A. TSCHUDY.

Series of hydroxypentamminoplatinic salts. L. CHUGAEV AND V. KHELOPINE. *Compt. rend.* 161, 699-700 (1915).—By passing a current of ozone through a soln. of 1 g. Peyrone's chloride and 2 g. $(\text{NH}_4)_2\text{CO}_3$ containing excess NH_4OH , a ppt. of hydroxypentamminoplatinic carbonate, $[\text{Pt}(\text{NH}_3)_5(\text{OH})_2(\text{CO}_3)_2]$, was obtained, insol. in H_2O . By dissolving this compd. in AcOH the acetate was obtained, from which the chloride, rhombic tablets with 1 H_2O , and the nitrate, needles, were obtained. Many similarities exist between the soly., etc., of the derivs. of the above base and those of derivs. of $[\text{Pt}(\text{NH}_3)_5\text{Cl}]^{+++}$ and $[\text{Pt}(\text{NH}_3)_6]^{++++}$, on the one hand, and those of Ba^{++} on the other hand.

GEORGE W. MOREY.

The reactions between cobalt oxide and other metallic oxides at high temperatures. J. A. HERDVAL. Upsala. *Z. anorg. allgem. Chem.* 93, 313-9(1915); cf. *C. A.* 9, 2844, 3039.—The constitution of Rinman's green is discussed, and it is concluded that the evidence in favor of the components of the solid soln. being $\text{CoO} \cdot \text{ZnO}$ and ZnO outweigh those in favor of their being CoO and ZnO (cf. *C. A.* 8, 1715). Expts. with CoO and the following oxides were made at 1100° and at 1300° , to see if compds. were formed. With Cu_2O , Ag_2O , CuO , BeO , CaO , SrO , BaO , CdO , PbO , Bi_2O_3 , La_2O_3 , ZrO_2 , ThO_2 , CeO_2 , no compds. are formed. Cr_2O_3 gives octahedra of the spinel $\text{CoO} \cdot \text{Cr}_2\text{O}_3$. Fe_2O_3 and Mn_2O_3 both give cryst. products, but the melts were too opaque for microscopical examn. Ignition of CoO with SiO_2 gave crystals imbedded in a glass; ignition with TiO_2 gave $\text{CoO} \cdot \text{TiO}_2$, but no orthotitanate could be obtained. Compds. were also obtained with V_2O_5 , Cb_2O_5 and Ta_2O_5 . GEORGE W. MOREY.

The explosibility of uranium nitrate. ARNO MÜLLER. Magdeburg. *Chem. Ztg.* 40, 38-9(1916).—M. investigated the nitrate prep'd. by extg. 2 aq. solns. with Et_2O , 1 soln. containing little HNO_3 , the other much; the amt. influenced the compn. of the nitrate, but not the phenomena. The Et_2O soln. was evap'd. under vacuum, the residue cooled and poured on ice and the crystals dried by pressing. Analyses are given. Occasional triboluminescence was observed when the crystals were moistened with H_2O , but in only 3 cases out of 20 were there signs of decrepitation. Small amts. of gas were evolved, probably consisting of Et_2O and oxides of N. These phenomena appeared only with crystals from Et_2O soln. extd. from aq. soln. containing free HNO_3 , disappearing on recrystg. from H_2O . M. considers the phenomena due to the formation of an unstable compd. of a lower oxide of N with an $\text{U-Et}_2\text{O}$ addition compd. which is decomposed under certain chem. and physical conditions, among which is internal friction, but in which radioactivity has no part. Cf. *C. A.* 5, 1885; 6, 2368, 2577; 7, 702, 1449; 8, 1715. J. H. MOORE.

Oxidation of hydrazine. VII. Alleged role of nitrous acid in the formation of hydronitric acid. A. W. BROWNE AND O. R. OVERMAN. *J. Am. Chem. Soc.* 38, 285-302(1916); cf. Hale and Kunez, *C. A.* 6, 45.—No indication of the formation of appreciable quantities of HNO_2 or HNO could be obtained by treatment of $(\text{NH}_4)_2\text{SO}_4$ in H_2SO_4 soln. with oxidizing agents such as H_2O_2 , KClO_3 , $\text{K}_2\text{S}_2\text{O}_8$, KMnO_4 , hydrated Fe_2O_3 , KIO_3 , HgO and HgCl_2 under the conditions prevailing in the expts. of Browne and Shetterly on the oxidation of hydrazine (*C. A.* 2, 235). $(\text{NH}_4)_2\text{SO}_4$ in a soln. strongly acid with H_2SO_4 is but slightly affected by prolonged treatment with H_2O_2 , KClO_3 and $\text{K}_2\text{S}_2\text{O}_8$ at boiling temp. Addition of $(\text{NH}_4)_2\text{SO}_4$ to a reacting mixt. of N_2H_4 — H_2SO_4 , H_2SO_4 and H_2O_2 does not increase, but rather serves to decrease the yield of HN_3 . KNO_2 oxidizes $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ in H_2SO_4 soln. with the formation under comparable conditions of larger yields of HN_3 and of much smaller yields of NH_3 than are obtained by the action of H_2O_2 upon $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$. The theory of F. Sommer (*C. A.* 8, 306, 1932) in explanation of the formation of HN_3 and of NH_3 by the oxidation of N_2H_4 by means of oxidizing agents contg. no N is untenable. E. B. MILLARD.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Analytical and inorganic chemistry. E. KINDSCHER. *Fortschritte Chem.* 11, 119-131(1915).—A review of progress in this field for the year 1914. The subjects treated are: volumetric analysis, gravimetric analysis and colorimetry. L. H. A.

Potassium hydrogen carbonate as an acidimetric and alkalimetric standard. G. INCZE. *Z. anal. Chem.* 54, 585-602(1915).—A general discussion of the physical

and chem. properties of KHCO_3 , together with analytical and expt detail. I. concludes that KHCO_3 possesses all of the properties necessitating reagent for volumetric analysis. The salt has been used in the Hungarian labs. for over 30 yrs. Pure KHCO_3 is most readily converted into an alc. soln. of KOH ; recrystn. and purification are best carried out from aq. solns. with alc. The salt is not hygroscopic and undecomposed in the air; it is best preserved in crystals in a glass-stoppered vessel. *C. A.* 9, 2747.

Reagents for use in gas analysis. III. The specific absorption of pyrogallol in various pipets. R. P. ANDERSON. *J. Ind. Eng. Chem.* 10, 433 and following abstract.—The specific absorption of O by pyrogallol (cf. *C. A.* 9, 2199) in different forms of pipets was detd. The results showed that modified alkaline pyrogallol for use in pipets that are designed for the absorption of O without loss can be readily adapted for use in such pipets without loss in specific absorption. The modified pyrogallol soln. was prepd. from alkali of 1.50 d. was substituted, the drop time was pronounced except with the Dennis pipet. Cf. *C. A.* 10, 2199. E.

Reagents for use in gas analysis. IV. Phosphorus in solution. J. Ind. Eng. Chem. 8, 135-6(1916); cf. preceding abstract.—With a reagent oil, as proposed by Tzentnershver (cf. *C. A.* 4, 2081) absorption of O was in no case complete in a reasonable length of time. A Hemmick reagent is not suitable for detn. of O at ordinary temps. and a soln. is to be preferred. E.

Analysis of alkaline earth metals. C. REICHARD. *Pharm. Ztg.* 27, 877-9, 895-6, 913-4, 1035-6(1915); cf. *Chem. Ztg.* 27, 877-9, 895-6, 913-4, 1035-6(1915).—Freshly pptd. carbonates of Ca , Sr and Ba to oxides. (1) Triture a small portion with cold H_2O until the H_2O is satd., filter, and heat to dryness, moistened with H_2SO_4 and ignited until only the metal remains. (2) Residue is hygroscopic— Sr is present. (3) Residue remains, Ba is present.

Solubilities of the sulfates of barium, strontium, calcium and magnesium in acetate solutions at 25° and a criticism of the present methods for these substances by means of ammonium acetate solution. J. W. CHEM. SOC. 38, 310-6(1916).—Expts. have been made on the solubility of NH_4OAc solns. contg. between 0 and 21.37 g. of salt per l. by shaking an excess of solid sulfate in a thermostat for 12 to 16 hrs. Weighed sample to dryness, moistened with H_2SO_4 and ignited until only the metal remains after which this was weighed. Detns. of the d. have been made for vol. calcs. could be made. BaSO_4 and SrSO_4 dissolve slightly more in NH_4OAc solns. than in H_2O , so that a sep'n. from Ca is possible. Addition of 1% of $(\text{NH}_4)_2\text{SO}_4$ to the acetate soln. reduces the solubility and still allows the soln. of considerable amts. of Pb and Ca as sulfate. Procedure is suggested for detg. qualitatively any of the 4 elements immediately after the removal of the HCl group; boil the soln. down to dryness, add 1 cc. of H_2SO_4 (3 N) and an equal vol. of alc., filter and wash with i

Pb and Ca from Ba and Sr with 3 *N* NH_4OAc , sep. Ca and Pb with NaOH after evap. the acetate soln. with H_2SO_4 and gently igniting, acidify the NaOH soln. with HOAc and test for Pb with K_2CrO_4 . Ba and Sr are converted into carbonates by boiling with Na_2CO_3 and tested in the usual way. A small amt. of Ca will not appear in this test, but will be detd. after the $(\text{NH}_4)_2\text{S}$ group in the usual way. A large amt. of Ca may be detected in the residue after the NaOH treatment. Basic mercuric sulfate, if it forms a yellow ppt. when the alc. is added, may be dissolved with a few drops of HCl.

E. B. MILLARD.

Electrometric titration of vanadium. G. L. KELLEY AND J. B. CONANT. *J. Am. Chem. Soc.* 38, 341-51 (1916).—Vanadates may be titrated with FeSO_4 , using the change in the e. m. f. of a suitable cell as indicator. The conditions best suited to an accurate titration were low temp. (preferably 10°), high acid concn., small rather than large amts. of V, and low concn. of chromic and ferric salts. A comparison of the method here developed with 4 others in common use for detg. V showed that the new method agreed with the other ones except with the method of reduction with HCl and subsequent titration of the reduced V with KMnO_4 after removing the HCl with H_2SO_4 and evap. Oxidation of V to the pentavalent condition by HNO_3 was not satisfactory for quantitative purposes, but oxidation with KMnO_4 or $(\text{NH}_4)_2\text{S}_2\text{O}_8$ was satisfactory in the absence of Cr. The method has been applied to Fe-V alloys, and could be adapted to ores.

E. B. MILLARD.

Titrimetric determination of cadmium and zinc. H. ENELL. *Z. anal. Chem.* 54, 537-46 (1915).—**Iodometric detn. of Cd:** E. used solns. of pure $\text{CdSO}_4 \cdot \frac{8}{3}\text{H}_2\text{O}$ (minute trace Fe) which showed on gravimetric analysis 101.7-102%. A series of expts. in which the washed CdS ppt. was put in a glass-stoppered bottle with 50 cc. of H_2O and an excess of 0.1 *N* I soln., shaken, let stand some hrs., and titrated with 0.1 *N* $\text{Na}_2\text{S}_2\text{O}_3$ soln. gave (pptn. and washing at room temp.): 99.3, 100.4, 100.8, 99.3, 99.3%. Filtration of CdS is facilitated by warming to $40-50^\circ$ and washing with H_2O at $40-50^\circ$, but the I reaction is retarded, requiring 14-24 hrs. for completion. Results generally high, expts. showing 102.4, 103.9, 103.9, 101.9, 101.9%. CdS is pptd. by means of $(\text{NH}_4)_2\text{S}$ and heating on the water bath till the mixt. assumes a colloidal appearance, let cool somewhat, 10% HCl added dropwise till pptn. is complete, filtered, washed with H_2O at $40-50^\circ$ till washings are neutral, ppt. treated with I soln. as above, let stand 36 hrs., and titrated with $\text{Na}_2\text{S}_2\text{O}_3$. Results 101.9 and 101.3%. It is probable that the addition of a few drops of HCl, after the CdS-I mixt. has stood some hrs., would facilitate the action of the I on the small residue of CdS; then let stand a while, and titrate with $\text{Na}_2\text{S}_2\text{O}_3$. E. considers the iodometric method uncertain. **Titration of Cd with AgNO_3 :** To CdSO_4 (0.192 g.) soln. in a beaker, add excess of H_2S water, heat on the H_2O bath 15-20 min., cool to $40-50^\circ$, add 1 g. $(\text{NH}_4)_2\text{SO}_4$, and stir. Let settle, filter on a 9 cm. paper, wash with a 2% $(\text{NH}_4)_2\text{SO}_4$ soln., containing 20 drops of 10% H_2SO_4 to 250-300 cc. and warmed to $40-50^\circ$, till filtrate has no H_2S odor and gives no color with AgNO_3 . Place filter and ppt. in a 200 cc. glass-stoppered bottle, add 50 cc. H_2O , and shake till paper is pulped, add 20 cc. (an excess) of 0.1 *N* AgNO_3 soln., and shake. Add 5 cc. of 25% HNO_3 , shake, let stand some minutes, filter through a plug of cotton, wash with H_2O till washings give no test for Ag, add Fe'' alum, and titrate with 0.1 *N* NH_4CNS . Results: 101.66-101.86%. Not more than traces of Fe should be present; Cl ions must be avoided. **Titration of Zn with AgNO_3 :** Pure ignited ZnO was dissolved in 10% H_2SO_4 for expts. To 100 cc. of the ZnSO_4 (0.0814 g. ZnO) soln. add 10 drops of 10% NH_4OH and stir (soln. should be alk. and have NH_3 odor), add 2 cc. of 25% AcOH , and then H_2S water in excess. Let stand on H_2O bath 12-15 mins., let cool somewhat, add 1 g. NH_4NO_3 (contained less Fe than other salts tested), let ppt. settle, filter on 9 cm. paper, wash with 2% NH_4NO_3 soln. (previously made alk.

with NH_4OH and then mixed with 5 cc. of 25% AcOH) at $40-50^\circ$ till (test with AgNO_3). The detn. is completed as given under Cd, except of 0.1 N AgNO_3 are added. Results: 99.5 to 99.99%. E. believes that of analysts relative to the rapid decompn. of ZnS in the air are exaggerated the cause of error is probably due to minute amts. of FeS . To a soln. containing wts. of ZnSO_4 and FeSO_4 was added 10 cc. of 10% NH_4OH (the calcd. amt. the H_2O_2 , the mixt. heated gently, and 30 drops of 25% NaOH added ppt. was filtered off and washed with warm, very dil. NaOH . Filtrate were evapd. to 50-60 cc., excess AcOH added, then H_2S , etc., as above. was Fe-free, but Zn loss was between 7 and 8%. F. W.

The application of the paper pulp filter to the quantitative estimation of calcium and magnesium. S. L. JODIDI AND E. H. KELLOGG. U. S. Dept. Agr. *Inst.* 181, 217-32 (1916).—The Ca and Mg content of chestnut bark is determined with the aid of the paper pulp filter. The ash was dissolved in dil. HCl moved by the basic acetate sepn. *Ca determination:* A Gooch crucible is used, a somewhat larger, covered Pt crucible and the two are heated, cooled together. Ppt. the Ca as oxalate in an aliquot of the filtrate from the sepn.; collect the ppt. on a paper pulp filter in the gooch, wash with boiling water, dissolve the filter with hot dil. HCl , followed by hot H_2O , reppt. with NH_4OH and $(\text{NH}_4)_2\text{C}_2\text{O}_4$; after $1/2$ hr. on the steam bath, collect the ppt. on a paper-pulp filter and wash with hot H_2O . Transfer the gooch to the Pt crucible, over a burner, dry the contents, carbonize, ash and ignite to CaO , weigh together with the 2 crucibles. Or the final CaC_2O_4 ppt. and its pulp filter transferred to a beaker and the gooch washed with a hot soln. of 10 cc. in 350 cc. H_2O , which is collected in the same beaker; the oxalate is titrated at 70 to 80° . For satisfactory results, the concn. of the Ca, when ppt. should lie between 0.01 and 0.10 g. CaO per 200 cc. *Mg determination:* Dryness the combined filtrate and washings from the Ca detn. and ignite up the residue in dil. HCl , filter, and wash the insol. matter. Ppt. the combined filtrate and washings as MgNH_4PO_4 , collect on a pulp filter in the gooch with 2.5% NH_4OH . The prepn. of the gooch and its treatment after ppt. are as outlined under Ca. The Mg is weighed as $\text{Mg}_2\text{P}_2\text{O}_7$. This method greatly reduces the time factor, and is more economical in the use of filter than ordinary filtration. Also in *Chem. Eng.* 23, 60-5 (1916). JOSEPH S.

Detection of iron in filter paper purified with hydrofluoric acid. A. Z. *anal. Chem.* 54, 547-9 (1915); cf. *C. A.* 10, 322.—The Fe in impure filter papers is present mainly as a cellulose compd. (Fe^{++} cellulosate) and not as an oxide. On acidifying with HCl or H_2SO_4 and treating with KCNS the color only after oxidation by the air; the rose-red color after some time fades, and finally a permanent yellow, due to the formation of $\text{C}_2\text{N}_2\text{H}_2\text{S}_8$; Fe first forms $\text{Fe}(\text{CNS})_3$, which with HCl gives FeCl_3 and HCNS , the latter giving HCN and $\text{C}_2\text{N}_2\text{H}_2\text{S}_8$, while HCNS would remain colorless and decompose in the presence of H_2O into volatile products ($\text{HCNS} + \text{H}_2\text{O} = \text{COS} + \text{NH}_3$). If HNO_3 is used the red color results immediately with KCNS ; the permanent color does not form as the HCNS by the action of the air decomposes into NH_3 , H_2O , and CO_2 . G. concludes that for the immediate detection of Fe, dil. HNO_3 should be used for a permanent record HCl or dil. H_2SO_4 . Control detns. should be made. P. V.

Differential iodometry. I. Determination of periodates, iodates, chlorates in the presence of each other. O. L. BARNEBEY. *J. Am. Chem. Soc.* 38, 330-41 (1916).—Periodates in neutral soln. react with KI and yield I_2 .

titrated with Na_2AsO_3 in the presence of excess NaHCO_3 . Attempts to titrate this I with $\text{Na}_2\text{S}_2\text{O}_3$ gave erratic results unless a weak acid was added to remove the alkali formed. H_3BO_3 and borax together eliminate the difficulty and allow the titration with $\text{Na}_2\text{S}_2\text{O}_3$ at room temp. The periodate should be allowed to react completely with the KI before the titration is commenced, since periodates react with thiosulfates themselves. Iodate could be detd. in the presence of bromate and chlorate by adding 0.1 N iodide in 0.125 N HOAc at temps. of 3 or 4°, but it was necessary to det. and apply a slight correction for interfering bromate. Periodate, if present in this titration, would be detd. with iodate. Bromate could be detd. in the presence of chlorate with much less acidity, though weak acids will not cause the bromate to react completely. Dil. HCl was satisfactory for this detn. Chlorate in the presence of perchlorate could also be detd. by converting the former into iodate and titrating the iodate by liberating I (from the interaction of chlorate and iodide) in strong acid soln. and then dissolving the I in alkali. Various inducing agents were tried without success. Several detns. were made for each of the methods, and the checks obtained were usually good. The results for chlorate in the presence of perchlorate were always low unless the HCl was about 6 N. By a suitable combination of these methods all of the substances mentioned in the title could be detd. in the presence of each other and in the presence of perchlorates.

E. B. MILLARD.

Determination of oxy-acids of sulfur in admixture. O. BILLETER. *Schweiz. chem. Ges.; Chem. Ztg.* 39, 500(1915).—For the detn. of sulfites in the presence of thiosulfates B. uses a titrimetric method (with N Na_2S_2 soln.) based on the reaction: $\text{Na}_2\text{S}_2 + \text{Na}_2\text{SO}_3 = \text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{S}$. Titrate the soln. at b. p. in a current of CO_2 till the yellow color of the Na_2S_2 appears on the addition of NH_4OH ; add AcOH, expel H_2S by vacuum pump, and det. the total $\text{Na}_2\text{S}_2\text{O}_3$ with I soln. Trithionate behaves toward Na_2S_2 like a mixt. of sulfite and thiosulfate; I oxidizes it to trithionate: $\text{Na}_2\text{S}_2\text{O}_6 + \text{I}_2 + \text{H}_2\text{O} = \text{Na}_2\text{S}_2\text{O}_8 + 2\text{HI}$. Trithionate can be detd. by conversion to thiosulfate by the action of K_2S . After oxidation of the total S to SO_3 by means of Br, the SO_3 originally present may be obtained by difference.

F. W. SMITHER.

Purification of the residue from evaporating the ether and chloroform extracts in the forensic detection of alkaloids. A preliminary paper. A. CARDOSO PEREIRA. Lisbon. *Chem. Ztg.* 40, 39(1916).—The Et_2O ext., prepd. according to Otto, is freed from Et_2O , made alk. with NaOH soln., treated with a few cc. H_2O_2 , boiled a few min., cooled, and the tests applied in the usual way. Some alkaloids, as strychnine, nicotine, coniine, are not altered by this treatment; others, as morphine, form unidentified oxidation products.

J. H. MOORE.

Colorimetric determination of acetylene. E. R. WEAVER. *J. Am. Chem. Soc.* 38, 352-61(1916).—The gas to be investigated is conducted into ammoniacal CuCl contg. gelatin and EtOH, and the red colloid so obtained is compared colorimetrically with a standard, which may be a dye or a piece of ruby glass. Definite conditions have been worked out for concn. of the reagents. A soln. of chromanilbraun R, carmoisine B and gum arabic was used as color standard. The method is very sensitive, amts. of 0.03 mg. may be detected and amts. of 2 mg. detd. to better than 0.05 mg. H_2S and large amts. of O and CO_2 interfere with the test and have to be removed first.

E. B. MILLARD.

A chemical paradox. O. DE VRIES. *Chem. Weekblad* 12, 1000-1(1915).—When methyl orange is added to a satd. ZnCl_2 soln., its color changes to a deep reddish purple. An addition of dil. HCl, e. g., 0.1 N, changes this color to orange and yellow (neutral tinge), an excess of dil. HCl turns it to reddish orange. Congo paper behaves in a similar paradoxical manner; it gives with ZnCl_2 soln. a blue color, which changes to red on the addition of H_2O and even of dil. HCl; an excess of HCl is required to pro-

132

Since the normal acid color (a bluish purple). The behavior of other chlorides, however, is quite normal. V. presents the following explanation: The red color of methyl orange in the presence of ZnCl_2 is not the real "acid" color but is caused by the formation of deep red compds. with ZnCl_2 , which are decompd. by H_2O . That the addition of dil. HCl at first causes a yellow color can be explained by the diminishing of the ionization of the HCl mol. through the large amt. of ZnCl_2 present, an excess of HCl being necessary to overcome this effect and to produce the real "acid" color of methyl orange.

Color reactions (RUDDIMAN) 17.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Mineralogical and geological chemistry. B. GOSSNER. *Fortschritte Chem.* 11, 107-18 (1915).—A review for the period Mar., 1914, to Mar., 1915. L. H. A.

Studies on asterism. PAUL KAEMMERER. Dresden. *Centr. Min. Geol.* 1915, 524-42, 546-53.—The theoretical and mathematical basis for Kalkowsky's conclusion (*C. A.* 9, 3192) that asterism in opalescent quartz is due to ultramicroscopic inclusions is discussed. The nature of the inclusions cannot be detd. and they may be merely hollow spaces of cylindrical outline, but the observations as to the light phenomena they produce are shown to be in accordance with the orientation inferred by K. and others. E. T. WANDTKE.

The crystals of maleic anhydride. O. MÜGGE. Göttingen. *Centr. Min. Geol.* 1915, 481-2.—Crystals of maleic anhydride are described crystallographically and optically, the results agreeing in most respects with those previously obtained. Two interesting phenomena are exhibited: in the air deliquescence occurs, crystal faces developing etch-figures, while conchoidal fracture surfaces become completely dulled much more rapidly; a similar relationship is shown by quartz when attacked by HF . In addition gliding ("Schiebung") occurs parallel to {101}, and the action of the moisture of the air on the resulting lamellas causes a scar-formation ("Vernarbung") similar to that observed on natural twinned minerals calcite, rutile, etc.. A. W.

Bismuthinite from Brosso. E. ARTINI. *Rend. accad. Lincei* 24, 249-51, 1915; *Ann. chim. applicata* 4, 280-90.—This mineral, discovered by A. at Brosso, is very rare in Italy, having been found heretofore only at Booccheggiaro. It occurs in bacillary aggregates or in fine, bright prisms. In the same mineral deposit A. found a member of the lepto-chlorite group, its observed characters pointing to its being probably cronstedtite. S. LEVY.

Hematite from Kakuk Mountains. KARL ZIMANTL. *Friedrichs Künig* 43, 150, 1915; continuation of *C. A.* 2, 1106.—A very full crystallographic description. E. T. W.

Review of publications on hematite. FERDINAND GOSKARD. *Bull. soc. franc. min.* 37, 115-24, 1914.—A resumé of article of preceding abstract. E. T. W.

The separation of calcium carbonate from solutions resembling sea water in composition. JOHANNES PERNE. *Dissertation Jena* 1913, 41 pp., *Neues Jahrb. Min. Geol.* 1915, I. Ref. 300-12.—At ordinary temps. calcite separates from solns. of pure NaCl , but the presence of other salts in soln. favors the formation of the unstable modifications of CaCO_3 . At 17-24°, in salt solns. having a compn. resembling that of sea water, vaterite separates out predominantly in spherulites and needles, together with some aragonite. This is caused by the NaCl salts, which being present in considerable

amt., increase the soly. of the CaCO_3 , and are thus responsible for the formation of the unstable modification. Ammonium salts when present tend to decrease the soly. of the CaCO_3 , and thus counteract the action of the Mg salts. The presence of a large amount of CaSO_4 in sea water leads to the sepn. of calcite. Conc'n. and, to a much greater extent, temp. of the soln. affect the sepn. of the unstable modifications. At $18-24^\circ$, when vaterite separates out, the conc'n. of the soln. only affects the amt. of the ppt. From solns. of pure CaSO_4 , at the same temps., calcite, as well as aragonite, separates out. At $8-11^\circ$, using a more conc'd. pptg. medium, these solns. ppt. vaterite. By treating solns. of pure CaSO_4 with Na_2CO_3 at this temp. calcite is formed. At 0° , hydrated CaCO_3 separates out. Above 30° aragonite alone is formed. The conditions of formation of the different modifications are not very well defined, since, when one form separates out predominantly, the next most stable modification also forms in considerable quantity. The formation of the natural forms of CaCO_3 , especially the oölites, is discussed in detail.

E. A. TSCHUDY.

Manganese-bearing albite from California. E. H. KRAUS AND W. F. HUNT. Univ. Michigan. *Centr. Min. Geol.* 1915, 465-7.—A black and a yellow mineral from the Caterina mine, Pala, Calif., have been analyzed and found to be albite, the former containing 1.71% MnO and 0.98% Fe_2O_3 . These substances are probably present as inclusions of manganite and goethite.

A. W.

Tourmaline in serpentine. A. LACROIX. *Bull. soc. franc. min.* 37, 75-6(1914).—L. shows that the discovery of tourmaline in serpentine by Duparc and Sigg (*C. A.* 8, 1734) bears out what he had noted in his *Mineralogie de France*, that mineralizers, especially B, are not confined to acid magmas, but occur in basic ones as well. Tourmaline, usually Mg-bearing, occurs in limestones, and even in gypsum or anhydrite beds, where metamorphosed by basic igneous rocks at several localities. Axinite, on the other hand, usually occurs in or near granite. (The article on a similar subject by Mügge (*C. A.* 5, 1383) is not mentioned.—ABSTR.)

E. T. W.

The crystal forms of mesolite. FERDINAND GONNARD. *Bull. soc. franc. min.* 37, 180-93(1914).—The crystal forms and angles which have been given by various authors for this mineral are summed up and discussed. Certain contradictory statements are probably to be explained by the occurrence of vicinal faces in place of the normal ones. It is in general not advisable to state crystal angles to fractions of minutes or seconds, since they may differ by many minutes from one specimen to another because of vicinal forms, variations in compn., and especially with the instrument employed for measurement, or, indeed, the "personal equation."

E. T. W.

Intumescent kaolinite. W. T. SCHALLER AND R. K. BAILEY. U. S. Geol. Survey. *J. Wash. Acad. Sci.* 6, 67-8(1916).—A white minutely cryst. mineral from Back Bone Mountain, LeFlore Co., Okla., has proved on examn. to be kaolinite, although it differs from previously described occurrences of this mineral in intumescent strongly before the blowpipe. The n 's are $\alpha = 1.561$, $\beta = 1.563$ and $\gamma = 1.567$ and agree with the values given by certain authors for this species; the mean value $n = 1.54$ given in some books is regarded as too low [for cryst. material, though not amorphous—ABSTR.]. Analysis by B. gave SiO_2 46.55, Al_2O_3 38.90, H_2O 14.04, sum 99.49%, agreeing closely with the theory for the mineral. The H_2O was found to behave normally, only traces escaping below 330° .

E. T. W.

Analysis of keffekilite from the Crimea. H. KASPEROVICH. *Mater. Kennn. geol. Bau. Russian Reich.; Festschr. V. Vernadskii* 1914, 121-2; *Neues Jahrb. Min. Geol.* 1915, I, Ref. 27.—Analysis of keffekilite, from Bakchisarai, nearly homogeneous in compn., gave SiO_2 51.00, Al_2O_3 16.28, Fe_2O_3 0.92, FeO 1.13, CaO 4.09, MgO 5.41, H_2O 19.79, CO_2 1.09, sum 99.71. After deducting 2.4% CaCO_3 which was

admixed with the material, these results correspond with the formula 5.09 SiO_2 , $1 \text{ R}_2\text{O}_3$, 1.19 RO , $6.63 \text{ H}_2\text{O}$.
E. A. TSCHUDV.

Deformations of crystals of betafite and beryl. A. LACROIX. *Bull. soc. franc. min.* 37, 101-7 (1914).—Crystals of betafite, normally isometric, with octahedron and dodecahedron, are occasionally found so deformed that they appear to be orthorhombic or tetragonal. In most cases this is due to unequal development of individual faces of one form, but in one locality the octahedron faces along one axis seem to oscillate with those of a trisoctahedron, (332), the dodecahedron at the same time oscillating with the tetrahexahedron (320); this phenomenon corresponds to that observed in pyrite crystals from Falls of French Creek, Pa. Crystals of monazite and strüverite are also occasionally deformed. In certain specimens of beryl the prism is replaced by a very long pyramid, and in others etch-figures yield dihexagonal pyramids. The etching in the latter was probably non-atmospheric.
E. T. W.

Microscopical and chemical study of phosphorite from the Ural Mts. V. CHIRVINSKII. *Bull. soc. oural amis. sci. nat.* 32, 105-20; *Neues Jahrb. Min. Geol.* 1915, I, Ref. 28.—A phosphorite vein occurs at the contact of granite and chlorite schists near the village of Pachkun, 15 versts (10 miles) from the Reshevsk smelter. The material is earthy at the surface, but becomes compact and sometimes brecciated at a greater depth. Analysis gave CaO 50.59, Fe_2O_3 1.84, Al_2O_3 1.86, P_2O_5 37.79, CO_2 2.13, F 2.32, Cl trace, H_2O 2.27 (hygroscopic 0.87, and crystn. 1.40), insol. 2.05, sum 99.85%. Loss on ignition 4.84%. This analysis corresponds with $\text{Ca}_3(\text{PO}_4)_2$ 82.50, CaF_2 4.76, CaCO_3 4.84%. The vein is probably of hydrothermal origin. It is the first phosphorite deposit of this type found in Russia.
E. A. T.

Theoretical considerations governing persistence of ore. T. A. RICKARD. *Min. ing Sci. Press* 112, 83-8 (1915).—R. further develops the idea (cf. C. A. 9, 1020) of persistence of ore, from modern theories governing the origin of ore-bodies: mineralization, secondary enrichment, structural relationship, the continual changes in the ores proper, and the probably young geological age of most deposits. The point is brought out that the above agencies of ore formation will be greatly modified with depth as pressure and temp. increase, and the ground becomes impervious to circulating waters.
C. BRAMSON.

Pneumatogenous ore deposits. A. SACHS. Breslau. *Centr. Min. Geol.* 1915, 501-4.—In S.'s previous paper (C. A. 9, 2046) pneumatogenous ore deposits were referred to, but only pneumato-epigenetic or contact deposits were described. In the present article several types regarded as pneumato-syngenetic are discussed, comprising: Primary Sn-ore deposits, where SnF_4 and H_2O , introduced by granitic magmas, reacted to form SnO_2 and HF , the ores depositing from the vapor condition; ore deposits in propylitized rocks, where it is suggested that FeCl_3 and AuCl_3 vapors reacted with H_2S to form Au-bearing pyrite; and Hg-ore veins, which are thought to have been formed by reactions of vaporized Hg compds. with H_2S . In the two latter cases subsequent action by H_2O , which S. regards as a condensation product of steam originally dissolved in the magma, but given off on its solidification, has produced many secondary minerals and obscured the primary nature of the deposit.
A. W.

The chemical and geological distinction of coal from lignite. A. SACHS. Breslau. *Centr. Min. Geol.* 1915, 475-8.—S. accepts the chem. distinctions worked out by Donath and Rzehak (C. A. 8, 2139) but believes that they have not recognized the geological relationship between coal and lignite. He suggests that the coals of the lower Cretaceous (and earlier periods) have formed (sich gebildet) as coal, those of the Upper Cretaceous (and later periods) as lignite.
A. W.

A new petrographic type, manjakite. A. LACROIX. *Bull. soc. franc. min.* 37, 68-75 (1914).—A rock of granoblastic texture, containing garnet, biotite, hypersthene; a little labradorite, and accessories, is described. The hypersthene was sepd. by a heavy soln. and analyzed by Boiteau and gave the results under (I) below. The garnet was analyzed by Pisani (II). The rock as a whole was also analyzed by B. (III):

	D.	SiO ₂	TiO ₂	Al ₂ O ₃	Fe ₂ O ₃	FeO	MnO	MgO	CaO	Na ₂ O	K ₂ O	P ₂ O ₅	H ₂ O ⁻	H ₂ O ⁺
I.	3.52	48.17	0.28	8.17	3.95	17.21	...	22.09	0.28	...	...	...	...	...
II.	3.80	41.10	...	22.40	...	23.40	0.44	11.12	1.92	...	...	...	...	...
III.	...	43.06	1.76	16.04	4.48	11.30	0.18	16.51	2.00	1.08	3.14	0.12	0.09	0.45

The hypersthene is unusual in the high Al₂O₃ and Fe₂O₃ content, the garnet is intermediate between almandite and pyrope, and the rock is remarkable in being high in Fe and Mg and in alkalis, especially K, at the same time. The rock belongs in absarakose (III. 5.3'.2'), but is different from any heretofore known, and is really related to the Al-bearing pyroxenites. Comparison with previous analyses shows nothing of closely related compn. The rock is, however, probably of igneous origin, and a new name, *manjakite*, from the locality (Ambohimanjaka) is proposed for it. E. T. W.

The quartz porphyries in the vicinity of Oberschöna, Thuringia. EMIL ULLRICH. Marburg. *Centr. Min. Geol.* 1915, 577-89, 606-16.—A detailed petrographic description. A. W.

The petrography of the basalt tuffs of the Habicht forest, near Cassel. ARTHUR BERNS. Marburg. *Centr. Min. Geol.* 1915, 483-500, 517-24.—The rocks are described petrographically in great detail, some of the fragments in the tuff showing rather unusual mineralogical associations. A. W.

Theory of the origin of clays. WILBUR STOUT. *Trans. Am. Ceram. Soc.* 17, 557-91 (1915).—Coal measure clays are believed to have originated from the residual products of Carboniferous plant life. Evidence favors the assumption that the plant residue was a clay-like compd. high in Al₂O₃. Under oxidizing conditions these residual products would build up a clay deposit. The theory accounts for the remarkable physical properties such as colloidal character, homogeneity, freedom from impurities and the const. relation between SiO₂, Al₂O₃ and H₂O. This theory requires no break in the growth of plants during deposition of clay and coal, only a change from oxidizing to preserving conditions, and it explains the origin of clay partings found in coal strata. C. H. KERR.

An organic oölite from the Ordovician. FRANCIS M. VAN TUYL. *Univ. Ill. Science* 43, 171 (1916).—An occurrence of siliceous oölite, the grains of which show org. structures of algal type, is reported. The matrix is dolomitic, and many of the grains have been wholly or partly changed to dolomite with obliteration of structure prior to silicification. E. T. W.

Space models for introduction into the study of eruptive rocks (NIGGLI) 1. Structure models according to W. H. and W. L. Bragg (MÜGGER) 1. A new polarization instrument (BAUER) 1.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Mineral and metal production in 1915. ANON. *Mining Eng. World* 44, 229-60, 266-83 (1916).—A long discussion with many statistics of the production in 1915 throughout the world and more particularly in the United States of the following sub-

stances: Au, Ag, Cu, Pb, Zn, Fe, steel, Al, Hg, Pt, Sn, Ti, W, Sb ores, Mn ore, Ra, V, U, potash, H_2SO_4 , portland cement, coal and petroleum. E. J. C.

Colloids and colloidal slimes. E. E. FREE. *Eng. Mining J.* 101, 249-54(1916).
—A general review and discussion. A bibliography is given. F. W. S.

The mechanical principles of the blast furnace. J. E. JOHNSON, JR. *Met. Chem. Eng.* 14, 38-45, 77-87(1916).—Of the total blast pressure of a furnace that is required to drive the air through the tuyères is in ordinary practice only 10%, while practically all the rest, except 1-3% needed to send the gases through the downcomer flues and burners, is spent in forcing the blast through the charge column. To calc. engine-house pressure add the combined resistances of the hot and cold blast mains and of the stoves which should not exceed 0.5 lb. The pressure drop in tuyères of circular cross section is expressed by the formula, $P_1 - P_2 = 2.4 (Tv^2/P_1 d^4)$, where P_1 and P_2 are abs. pressures without and within, T abs. blast temp. ($F^\circ + 460$), v the vol. of air passing each tuyère per min. measured in thousands of cu. ft., and d the diam. of the tuyère in inches. In furnace design careful account must be taken of the number and diameters of tuyères since the air-jet must be strong enough to reach the center of the hearth to prevent the formation of a cold cone but not so strong as to carry an excess to the center allowing pilasters of dead material to form on the walls between the tuyères. As a formula for detg. the blast pressure required to overcome the resistance of the charge column, J. proposes: $P_1^2 - P_2^2 = HK w^3/D^4$, where P_1 and P_2 are abs. pressures at tuyères zone and stock line, w wt. of air blown per min., H height of furnace, and D furnace diam. The value of K has been detd. from experience to be approx. 0.0008 and it remains fairly const. either for the fine Mesabá or the lumpy Southern ores. He discusses at length the 4 elements contributing to the support of the charge column, viz., (1) the upward pressure of the gas, (2) the friction on the sides of the shaft, a resistance difficult to measure but one which sometimes exceeds 100% of charge weight, (3) the vertical upward thrust against the downward converging slope of the bosh walls and (4) flotation pressure in the molten mass in the hearth which is itself more than sufficient to support the column. The height of furnaces that may be blown to full capacity is approx. 90 ft.; larger furnaces must be run with less than a proportionate amt. of air to allow for a regular descent of the charge. In the discussion of the principles which govern the shape of the furnace, numerous figures showing the changes evolved in the last 75 years are given. H. L. OLIN.

The Gellens process of treating refractory ores. G. A. GELIENS. *Mining Eng. World* 43, 473-4(1915).—The process effects the extn. of Au, Ag and Cu from coned. sulfides and sulfide ores containing antimonides, arsenopyrites, blende, chalcopyrite, pyrites, etc., and the sulfides and tellurides of Au and Ag, by treatment with NaOH and $KClO_3$, with aeration during amalgamation. H. L. OLIN.

Device for reversing open-hearth steel furnaces. ANON. *Met. Chem. Eng.* 14, 111(1916).—A description of the Schumann device for the above purpose. A clock makes elec. contacts at fixed time intervals, and the closing of the elec. circuit operates a 4-way valve which admits pressure to one end or the other of a hydraulic cylinder. All valves involved in the reversal of the furnace, as well as the oil burners if the furnace is oil-fired, are hung on cords with counterweights so that the movement of the piston in this cylinder makes all the necessary changes. The reversal may also be made at any time other than that for which the clock is set by operating a hand contact. An outline of the system is given in a sketch. W. L. BADGER.

Clarifying wash water from purifying blast furnace gas. ANON. *Stahl u. Eisen* 35, 829-33(1915).—An illustrated article showing various settling devices. CARLE R. HAYWARD.

Coal and coke efficiency in blast furnace operation. B. F. BURMAN. *Met. Chem. Eng.* 14, 137-40(1916).—**Coal efficiency:** In the interests of keeping the ash and S content of coal shipments below certain prescribed limits, and as an indicator of the improvement of methods at the mine for this purpose, the adoption of an "efficiency percentage" system is advocated. Standard values are obtained by computing the av. minimum values (dry basis) for the ash and sulfur for a year's coal output, and adopting them as standards for the next year's work. By assuming these values to represent 100% efficiency, the "efficiency" of any other percentage composition may be computed. **Coke efficiency:** The object of the efficiency system is not only to improve the quality, but to keep the coke at the same uniform value and physical structure. The value of the coke is improved by decreased ash, S and volatile matter, and an increased fixed-C content. Standard values for comparison may be obtained by computing the av. analysis (dry basis) of the coke for one year with fair max. and minimum limits defined. This analysis may be used for the coming year, and by assuming the av. max. value for fixed C, and the av. minimum values for moisture, volatile matter, ash and sulfur to represent 100% efficiency, the "efficiency percentages" of any other analysis may be detd. The total "analysis efficiency" of the coke is equal to the av. of the sum of the fixed C, volatile matter, ash, and S "efficiencies," the moisture "efficiency" being treated separately. The losses due to improper quality of the coke may be detd. fairly well by figuring the relative value of the coke used.

E. A. TSCHUDY.

A new process for making converter bottoms for the basic Bessemer process. E. BRÜHL. *Stahl u. Eisen* 35, 941-7(1915).—The dolomite bottom is packed in with tar and carefully dried attaining a max. heat of 500°. The bottom is not baked in the usual way as most of the tar would be burned out leaving the bottom porous. The hot metal of the first charge is allowed to bake the bottom, thus leaving much of the C of the tar as coke. Figures are given showing the superiority of the method.

CARLE R. HAYWARD.

Chrome-iron ore as lining for reverberatory furnaces. E. HALL. *Eng. Mining J.* 101, 267-8(1916).—An account of trials with chromite lining for the reverberatory-matting furnace at Silverspur, Queensland, Australia. Success was achieved with chromite, dry-masonry lining; large bottom blocks of chromite were bedded on a mixt. of clean blende and crushed chromite. Compn. of slag averaged: SiO_2 32, ZnO 25, PbO 5, FeO 20%, while the mat fall was under 3%. MgO bricks lasted a much shorter time than bricks of chromite or bauxite; the latter were therefore used in critical places (on the firebox side of the bridge, in the vulcatory arch, in the front above the skimming door, for jambs and arches of the side doors). The main drawback is the accumulation of chromite sand as a layer between the mat and the slag. This sand is too rich in Ag to be thrown away, and should be regularly skimmed out. It was found impossible to resmelt the residues (mixt. of chromite sand, slag, mat, and "bottoms") in a reverberatory matting furnace, but it can be done in a Pb blast furnace, with high column and large capacity. Possibly, when smelting straight Cu ore carrying but little Ag or Au, this material would be poor enough to reject.

F. W. SMITHER.

Pig-iron mixers with special reference to the most practicable size. FR. SPRINGORUM. *Stahl u. Eisen* 35, 825-9, 852-8(1915).—The value of the mixer in steel plants is discussed as well as its development from small mixers holding 775 tons to the modern mixers holding 2000 tons. Mixers are heated with blast-furnace gas, producer gas or oil. The three methods are discussed and costs compared.

CARLE R. HAYWARD.

Blast furnace smelting of cyanide precipitate. REGIS CHAUVENET. *Met. Chem. Eng.* 14, 96-9(1916).—The process consists in smelting the ppt. on a Pb basis, in a

small furnace constructed in miniature like a Pb-smelting furnace. Briquets are made consisting of dry ppt., 100 parts; PbO, 100-125 parts; blanket concentrate containing 35% SiO₂ and 30% S, 60-75 parts. With high Cu in the ppt. raw concentrate is used to form a mat; with low Cu it is added in the roasted state. The furnaces in use at Goldfield are of the cylindrical type, 20 in. at the tuyère line with steel jackets. The charge is 500 lbs. of Pb followed by briquets 100, old slag 40, borax 10, cupel bottoms 51, Fe₂O₃ 5 and coke 25. The Pb bullion obtained by this method contains 20% Au and 1% Cu while the mat averages 20% Pb and 50 oz. Au and 200 oz. Ag per ton. The latter is allowed to accumulate until a sufficient amt. is at hand for a separate run.

Cyanide process applied to antimonial ores. MACARTHUR, FORREST & Co. *Eng. Mining J.* 101, 224(1916).—A cheap process devised for treating the Sb-Au ores of the Murchison Range, Transvaal. The process is carried out at the United Jack Mine as follows: The ore is crushed in 2 No. 7 ball mills to 30-mesh, discharged to bins, and conveyed as required to 6 circular dissolving tanks (23 ft. 9 in. diam. and 8 ft. deep). Hot NaOH soln. is pumped upon the sands and drawn through them in much the same way that cyanide solns. are applied upon the Rand. The soln. is drained off to 3 carbonators, where it is treated with CO₂ from a CaO kiln. The Sb is pptd. as an amorphous sulfide, and the sludge is pumped to the ordinary type of filter press and pressed into cakes, which are finally dried and made ready for the market. The soln. from the filter press goes back to stock tanks for use over again. The sand residue is treated in the usual way by cyanide soln. to recover the Au.

H. L. OLIN.

Hydrometallurgy of lead. H. R. ELLIS. *Met. Chem. Eng.* 14, 122(1916).—Oxidized ores from Washoe County, Nevada, containing 10% of lead, nearly all present as sulfate, the rest being galena, and 10.0 oz. of Ag per ton, were leached with hot 20% brine soln. containing 0.5% of CuSO₄. The ore was crushed to 40 mesh. After diln. of the soln. and pulp with more hot brine soln. containing no CuSO₄, the clear liquid was drawn off and the operation repeated with fresh brine, finally giving the settled pulp a displacement wash with hot water. The soln. from the vats was passed through cement copper to recover the silver and then through scrap iron to recover the lead. An extn. of 85% of both the Pb and Ag values was obtained. Old concn-

trates containing quite a percentage of arsenic and sulfides, after receiving an oxidizing roast, were treated by the above method with an extn. of only 45-50% of the contained Pb and Ag. The largest amount of ore treated at one time was one ton.

F. W. S.

Thermoelectricity of special steels. E. L. DUPUY AND A. M. PORTEVIN. *Rev. metal.* 12, 657-79(1915).—The thermoelec. properties of a number of special steels were measured between -78.6° and 0° and between 0° and 100°. The results of this investigation show that the curve representing the thermoelec. power of a steel as a function of its compn. (1) takes the form of an hyperbola where the metal added exists in solid soln. and that (2) where there is a mixt. of 2 phases the curve is nearly a straight line. Special steels may thus be classed into 2 groups in regard to their thermoelec. properties. Special steels of Ni, Mn, Si and Al give a curve in the form of a U, from which it is inferred that the metal added exists in the steel in the form of a solid soln. Special steels of Cr, W, and Mo show curves in which there is at first a sharp fall indicating, as in the preceding, a partial solid soln., followed by a rise and continuing more or less parallel to the x-axis. This gives some idea as to the limit of soly. in the solid state of the metal added. This is particularly of interest in the case of the duplex alloy present in carbon steel. Here the C seps., when satn. is reached, either as a constituent of pearlite or an extra-eutectic. The thermoelec. properties of special steels permit the classification of the latter in a manner sufficiently sharp to furnish valuable information complementary to their other physical and mechanical properties.

The latest improvements in Brinell hardness-testing machines. ANON. *Met. Chem. Eng.* 14, 59-60(1916).—A description of the Scimatco-Brinell hardness-testing machine.

W. T. H.

The relation between maximum strength, Brinell hardness and scleroscope hardness in treated and untreated alloy and plain steels. R. R. ABBOTT. *Proc. Am. Soc. Testing Materials* 15, II, 42-61(1915).—When steels have been heat-treated to a strength of over 200,000 lb. per sq. in. it becomes difficult and expensive to cut a test bar for physical tests. It is becoming customary to test the hardness of the finished steels and from that infer the other physical properties. In order to test the relation-

ship between the various physical properties some 300 different types of steel were selected, and 25 test bars cut from each. Each test bar was heat-treated in a different way. The following results were obtained: C steels, Brinell hardness is proportional to max. strength; scleroscope hardness is proportional to max. strength; Brinell hardness is proportional to scleroscope hardness. The same relations hold for Ni, Cr-V, and Cr-Ni steels of various compns. The equations of the various linear functions were detd. D. B.

Internal stresses developed by different quenching mediums and their effects. H. V. WILKE. *Proc. Am. Soc. Testing Materials* 15, II, 27-41(1915).—The internal stresses resulting from the quenching of a 9 $\frac{1}{2}$ in. cylinder in various media, and under various conditions were detd. Slow and mild water quenching results in a fiber stress of 45,000 lb. per sq. in.; light tempering oil about 35,000; heavy tempering oil about 24,000, fish oil about 30,000. It is shown that the tensile properties of rapidly cooled steel are superior to those of one slowly cooled. However, high rate of cooling may easily develop internal fracture. Metallurgists are confronted with the alternative of conservative physical properties, or of high elastic limit, elongation and reduction of area with attendant possibility of internal fracture. It was also found that the effect of the initial temp. of the quenching medium on tensile properties is not serious, but it affects the internal stresses. D. B.

The fatigue of nickel and iron wires when subjected to the influence of alternating magnetic fields of frequency 50 per second. W. BROWN. *Sci. Proc. Roy. Dublin Soc.* 14, 336-44(1915).—With Ni wire the harder the wire or the greater its rigidity, the greater is the fatigue. The fatigue rises rapidly with the time and reaches a max. With Fe wire the time to reach max. fatigue is much greater than in the case of Ni. Fe in a comparatively soft state could not be fatigued at all. D. B.

The subsidence of torsional oscillations of iron wires and alloys when subjected to the influence of alternating magnetic fields of frequency 50 per second. W. BROWN. *Sci. Proc. Roy. Dublin Soc.* 14, 393-404(1915). D. B.

The subsidence of torsional oscillations and the fatigue of nickel wires when subjected to the influence of alternating magnetic fields of frequencies up to 250 per second. W. BROWN. *Sci. Proc. Roy. Dublin Soc.* 14, 521-8(1915).—The time taken to effect the max. fatigue appears to vary inversely as the frequency of the applied alternating magnetic field. D. B.

Elastic limit. T. D. LYNCH. *Proc. Am. Soc. Testing Materials* 15, II, 415-36(1915). D. B.

The magnetic transformation of cementite. K. HONDA AND H. TAKAGI. *Sci. Rep. Tohoku Imp. Univ.* 4, 161-8(1915); *Engineering* 100, 665-7(1915).—By cooling, the magnetic transformation of cementite begins at 215° and by heating it ends at the same temp. This is the critical temp. of the cementite. In former expts. steels with a C content from 0.14 to 1.5% showed almost the same critical temp. as the latter steels. Since the ferro-magnetic compounds of Fe have critical temps. peculiar to them it may be concluded that the carbides may possess different critical temps. But since the various steels, with from 0.14 to 4.2% C., show a single transformation between room temp. and 700°, it is probable that the only carbide existing at ordinary temp. is cementite. D. B.

Apparatus for determining the critical point in iron and steel. ANON. *Iron Age* 96, 928(1915). D. B.

The nature of the A₂ transformation in iron. K. HONDA. *Sci. Rep. Tohoku Imp. Univ.* 4, 169-214(1915).—A critical study of recent investigations. The heat effect corresponding to the A₂ transformation takes place over a wide range of temp.

The A_2 transformation is, therefore, probably not an allotropic change. Benedick's view that the A_2 is a change associated with the A_1 transformation is not plausible because it rests on the belief that the heat effect at A_2 is due to the residual effect of the A_1 transformation brought down by the impurities in the Fe; but *pure* Fe shows a heat effect. In a definite magnetizing field, the magnetic transformation takes place in a certain definite interval independent of the rate of cooling or heating. This result weakens the allotropic theory. Heat evolution in Fe or Ni during cooling does not appreciably change for different magnetizing fields. Since the heat evolved or absorbed at A_2 is known to be about $1/2$ that at A_1 , the discontinuity in the curve of expansion should be of the same order of magnitude as that at A_1 , if A_2 is allotropic like A_1 . This is not the case. The A_2 transformation is not allotropic but is some intermolecular change which takes place gradually in the α phase and in a large interval of temp. From the standpoint of the phase doctrine, β -iron is to be rejected, although the name may be retained for convenience. Also in *J. Iron Steel Inst.* 91, 199-254(1915).

D. B.

The magnetic study of the A_2 transformation in pure iron. K. HONDA AND H. TAKAGI. *Sci. Rep. Imp. Tohoku Univ.* 4, 261-5(1915).—A magnetic analysis of the A_2 transformation was made on 4 specimens of pure Fe. The results agreed well with a thermal analysis made by another investigator. The results on the whole are not favorable to the theory of magnetons, as given by Weiss.

D. B.

The partial protection of pieces of steel subjected to cementation. F. GIOLITTI. *Atti accad. sci. Torino* 50, 414-9(1915).—L. Guillet and V. Bernard (*C. A.* 8, 3000) obtained negative results in studying the protective effect of metallic layers of various thickness and qualities against carburizing action of cementation agents. G. has obtained results somewhat different and believes that the protective action of metallic deposits depends to a large extent on the special conditions under which the deposit is formed and on the surface of the steel, so that the protective action may be varied within very wide limits. Cementation expts. are described with a very mild steel heated with wood charcoal in an atm. of CO. An electrolytic deposit of Ni (0.05 mm. thick) was made on $1/2$ of 1 cylinder and it was cemented 40 mins. at 900°. A photo micrograph shows that the Ni effectively protected the surface of the steel from cementation. Similar expts. with specimens cemented at 1000° for 1 hr. show that the Ni layer at this temp. does not protect as well as at 900°, but it does have the effect of diminishing somewhat the rapidity and intensity of the carburization. A specimen protected with an electrolytic Cu deposit 0.05 mm. thick cemented at 1000° for 1 hr. showed a cemented layer a little thinner than on an unprotected specimen and a little thicker than on the preceding. A specimen $1/2$ protected by electrolytic Cu cemented at 900° for 40 mins. showed uniform cementation.

E. J. WITZEMANN.

Controlling the sulfur in melting pig iron. W. M. CARR. *Foundry* 43, 189(1915).—S cannot be kept very low, nor reduced, in the cupola; it can be in the open hearth. As the cupola requires less fuel, it is suggested that where low-S cast Fe is to be produced, the metal should be melted in a cupola and run into an open hearth for the elimination of S by adding Fe-Mn. The metal may be held in the open hearth almost indefinitely, and the C and Si may be regulated by suitable additions.

H. W. GILLET.

The production and properties of electrolytic copper. B. WILBOURN. *Electrician* 76, 235-7(1916).—The manufacture of Cu wire, including rolling, annealing, jointing and testing is described. The modulus of elasticity should be taken as 18,000,000 instead of 16,000,000, the figures usually used. Tensile strength and the effect of temp. are also reviewed.

W. E. RUDER.

Recent processes for improving the physical properties of zinc. E. H. SCHULZ. *Chem. Ztg.* 39, 547(1915).—A lecture before the Ges. deut. Metallhütten-u. Bergleute. The addition of about 6% Cu and 3% Al increases markedly the hardness and toughness of cast Zn. It also produces a more homogeneous metal which contracts but slightly on cooling. Pressing or rolling improves the qualities of Zn. E. H.

Corrosion of iron. K. P. GRIGOROWITCH. *Rev. soc. russe de metal.* 1, 70-88, 115-47(1914); *Rev. metal.* 12, *Extraits* 242-7; *J. Soc. Chem. Ind.* 34, 1253.—The electrolytic corrosion of Fe in contact with different metals and other substances was studied. Contact with FeS was found to promote corrosion; the sulfide was not dissolved during the process, its electrolytic potential being lower than that of metallic Fe; the greater ease of oxidation of Fe contg. S (as MnS) may thus be due to local currents produced between the ferrite and MnS. The divergence of opinion as to the relative corrodibilities of cast and wrought Fe and steel is regarded as proceeding from inherent differences in the methods of investigation employed. The influence of thermal treatment on the soly. (corrosion) and electrolytic potential of various steels was detd.; the soly. of ordinary cast steel was greater after quenching, or reheating to 400°, and generally least after annealing but varied only slightly with the C content; the electrolytic potential of the steels varied with the temp. and time of reheating, but more with regard to the intermediate than to the initial and final values. E. J. C.

Experiments on the corrosion of molybdenum steel. LESLIE ARCHISON. *J. Chem. Soc.* 107, 1531-8(1915).—A sample of pure C-steel was compared with a series of similar steels containing up to 20% Mo as regards the tendency to corrode in 3% brine, 1% H₂SO₄, 10% H₂SO₄ and in tap water. The results on the whole indicate that the addition of small quantities of Mo to pure steel increases at first the tendency to corrode, but when 15% or more of Mo is present the corrosion becomes less. W. T. HALL.

Recent progress in corrosion resistance. D. M. BUCK. *Iron Age* 95, 1231-9 (1915).—The statement at the end of the abstract of this paper in *C. A.* 9, 3212, that G. H. Charls in discussion confirmed B.'s conclusions is incorrect. E. J. C.

The temperature-concentration diagrams of carbon with manganese, nickel and iron. W. BORMAN. Danzig. *Dissertation Kgl. Techn. Hochschule, Danzig* 54 pp. (1915).—The b. p. of pure Mn at 30 mm. was found to be 1510°; the b. p. of molten Mn satd. with C, 1526° at 30 mm. The soly. of C in molten Mn between 1200° and 1300° was studied. Pure Ni b₃₀ 2341°; Ni satd. with C b₃₀ 2490°. On the Ni-C diagram the line showing where the mixed crystals begin to sep., the eutectic line, and the eutectic point were detd. For the 3 diagrams the compn. of the vapor phase was detd. The app. is described in detail with the calibrations of the thermal couples, etc. D. B.

The system cobalt-carbon at temperatures above 1500°. F. KEILIG. *Dissertation Kgl. Techn. Hochschule, Danzig* 28 pp.(1915).—C shows with increasing temp. an increasing soly. in Co. At the highest temp. measured, the soly. was 9.24% C at 1 atm. From 2100° to 2200° the presence of Co₂C was detected in the melt. The soln. satd. with C b₃₀ 2415° ± 10°. The vapor from this soln. contained 2.0 ± 0.6% C. Pure Co b₃₀ 2375° ± 10°. D. B.

The binary aluminium alloys. HERMANN SCHIRMEISTER. *Stahl u. Eisen* 35, 649-52, 873-7, 996-1000(1915).—The effects of the following elements on Al were discussed with many tables and curves: Zn, Mg, Cu, Ni, Co, Fe, Sb, Si, Cd, Sn, Pb, Bi, Cr, Mn, Wo, Mo, V, Ti, Zn, Ta. CARLE R. HAYWARD.

Metallographic investigation of the system tellurium and selenium. Y. KIMATA. *Mem. Coll. Sci. Imp. Univ. Kyoto* 1, 119-21(1915); *J. Soc. Chem. Ind.* 34, 1211.—Te

and Se form two series of solid solns. The liquidus passes from the m. p. of Te 441° , on the one hand, and that of Se 197° , on the other, to a minimum at Se 95% and 130° ; at this point the crystals have the same compn. as the melt. Se and the Se-rich reguli have a strong tendency to solidify to glassy masses. E. J. C.

The alloys of tellurium and lead. M. KIMURA. *Mem. Coll. Sci. Imp. Univ. Kyoto* 1, 149-52(1915); *J. Soc. Chem. Ind.* 34, 1211.—The system Te-Pb yields only one compd., PbTe, m. 904° . There are no solid solns. The liquidus runs down from 441° , the m. p. of Te, to an eutectic point at 24% Pb and 412° , up to a max. at 61.89% Pb (PbTe) and 904° , and then down to the m. p. of Pb, 326° . E. J. C.

Metallographic investigation of the system antimony and tellurium. Y. KIMATA. *Mem. Coll. Sci. Imp. Univ. Kyoto* 1, 115-8(1915); *J. Soc. Chem. Ind.* 34, 1211.—The m. p. of Sb is 627° , that of Te is 442° . Only one compd. exists, Sb₂Te₃, m. 620° . This compd. forms with Sb an eutectic melting at 540° and contg. 27-28% Te; and with Te an eutectic melting at 420° and contg. a little under 90% Te. No solid solns. are formed. E. J. C.

Manganese-nickel alloys. A. D. DOURDINE. *Rev. soc. russe de metall.* 1, 11-23, 341-95(1912); *Rev. metal.* 12, 125-33(1915); *J. Soc. Chem. Ind.* 34, 1058.—The liquidus curve drops sharply from the m. ps. of the pure metals (Mn 1235° , Ni 1451°) to a flat minimum between Mn 56 and 63% at a little above 1000° . The alloys contg. Mn 0-38% and 71-100% consist of solid solns., but the thermal curves for the alloys with Mn 38-56% and 63-71% show certain peculiarities which appear to indicate the existence of 2 modifications, stable and unstable, of the compd. MnNi (Mn 48.37%). The microscopic structure of the alloys is described and discussed with reference to the thermal effects observed. E. J. C.

The manufacture and uses of alloy steels. H. D. HIBBARD. U. S. Dept. Interior, Bur. Mines, *Bull.* 100, 72 pp.(1915).—The manuf., methods of working, heat treatment, compn., properties and uses of alloy steels are described. W, Cr, Mn, Ni, Ni-Cr, Si, high-speed tool, and Cr-V steels are considered. A comprehensive bibliography is appended for each steel. E. A. TSCHUDY.

Choice of alloys for water works design. H. CARPENTER. *J. Am. Water Works Assoc.* 2, 351-8(1915).—Among the bronzes the so-called naval bronze is usually satisfactory. Resistance to corrosion is aided by replacing about 3% of the Cu with Pb. Monel metal is the most perfect alloy but is quite expensive since it is difficult to obtain sound castings. It is believed that Ni steel has not been given sufficient considerations by the engineer. W. F. LANGELIER.

The properties of cold-worked metals. II. Methods of measuring small changes in density produced by annealing. R. G. PARKER AND T. M. LOWRY. *J. Chem. Soc.* 107, 1160-8(1915); cf. *C. A.* 9, 2756.—The small changes in d. produced by annealing may be detd. by means of the pycnometer, by suspension in water or by recording the change in vol. with the aid of the dilatometer. The precautions necessary for accurate work with the pycnometer and with the dilatometer are described in detail. The use of the former instrument is illustrated by a series of measurements on a dental alloy and on Cu and the use of the dilatometer is illustrated with measurements on Sb. W. T. HALL.

Manganese-bronze. J. B. RHODES. *Metal Ind.* 13, 462(1915).—A description of its manufacture from various scrap materials. D. B.

Phosphorus limit in malleable castings. E. TOUCHEDA. *Iron Age* 96, 92-46, (1915).—Dynamic tests were made on specimens of different P content by detg. the number of blows required to break the specimen. When the amt. of combined C is

very low the evil effects of P are slow to make themselves felt. Unsoundness is often caused by shrinkage. D. B.

Materials employed in case hardening. R. A. MILLHOLLAND. *Iron Age* 96, 1041-2(1915).—M. compares the advantages of natural and manufactured materials for case hardening. D. B.

Case hardening retorts and furnaces. R. A. MILLHOLLAND. *Iron Age* 96, 1111-4 (1915).—Notes on materials employed, methods of packing, and furnaces. D. B.

The process of case hardening. R. A. MILLHOLLAND. *Iron Age* 96, 1166-7 (1915).—The effect of high temp., influence of time and temp., case and core treatment are described. D. B.

High temperature flames in metal working. H. R. SWARTLEY, JR. *Iron Age* 96, 1122(1915).—A review of the present practice in the use of oxy-acetylene and oxy-hydrogen flames. D. B.

The application of electricity to the heating of metals. F. L. BISHOP. *Electrician* 76, 158-9, 189-90(1916).—A discussion of the recent developments, present status and limitations in the application of electricity to the heating of metals for the purpose of annealing, hardening or other heat treatments. B. discusses briefly, with cuts, the different types of furnaces employed in lab. work, and points out the application of these furnaces to commercial service, where such application has been made

F. W. SMITHER.

General electric practice in sherardizing. ANON. *Iron Age* 96, 1108-10(1915).—The apparatus used and practical details are given. W. E. RUDER.

Electric welding as developed to date. C. B. AUHL. *Iron Age* 96, 1356-9, 1414-6 (1915).—The LaGrange-Hoho and Thomson processes are described, of which only the latter is used in America. W. H. BOYNTON.

Oxy-acetylene welding practice. S. W. MILLER. *Machinery* 22, 404-6, 461-7 (1916); cf. *C. A.* 10, 37.—Pure rolled sheet Al or Al sheet with but little alloy can be "oxy-acetylene welded" with excellent results providing a good flux is used. The resulting weld will be as malleable as the original sheet. Directions are also given for welding Fe and other metal sheets. C. G. F.

Tailings sampling device (SHAW) 1. Thermal insulation of high-temperature equipment (BOECK) 4.

Blast furnace. W. P. THORNTON. U. S., 1,167,729, Jan. 11. Metal shell and H₂O-trough structure.

Furnace brick. W. J. HILLIS. U. S., 1,168,211, Jan. 11. Ground flint 20, is mixed with plastic clay 10, carborundum 30 and "binding" or "hard flint" clay 40% to form a brick which is adapted to stand extreme heat, *e. g.*, as a lining of open-hearth steel furnaces.

Desulfurizing and smelting ores. A. S. DWIGHT. U. S., 1,169,069, Jan. 18. Fine ores are sintered into thin layers or blocks without addition of any binder and the sintered material is fed gradually edgewise into a smelting flame.

Ore-concentrating and amalgamating apparatus. W. L. MCLEAN. U. S., 1,169,083, Jan. 18.

Obtaining lead or zinc in an electric furnace. A. HELFENSTEIN. U. S., 1,167,998, Jan. 11. Pb or Zn ores are distd. in an elec. furnace and the metal vapors and gases are exhausted from the distg. zone and the CO and CO₂ are used for heating the incoming charge in a preheating zone. The gases generated in the latter are drawn off

to avoid contamination of the metal vapors with oxide-forming gases and to minimize or prevent formation of metallic dust.

Extracting zinc from ores. F. LAIST and F. F. FRICK. U. S., 1,167,700, Jan. 11. ZnS ore containing Fe is roasted with MnS or MnCO_3 , leached with dil. H_2SO_4 , oxidized with MnO_2 to convert ferrous into ferric Fe and the latter is pptd. by $\text{Ca}(\text{OH})_2$. The purified soln. is electrolyzed to deposit the Zn, using insol. anodes, and the acid soln. remaining which contains highly oxidized Mn compds. is used for extg. Zn from other portions of roasted ore.

Extracting zinc from ores. F. LAIST and F. F. FRICK. U. S., 1,167,701, Jan. 11. Zn is recovered from oxidized ores containing Fe by leaching with hot dil. H_2SO_4 , oxidizing the ferrous compds. in soln. by treatment with MnO_2 , purifying the soln. by addition of an excess of calcined ore and action of MnO_2 , and electrolytically depositing the Zn with simultaneous regeneration of MnO_2 .

Zinc-extraction apparatus. M. M. PEARLMAN. U. S., 1,167,925, Jan. 11. A retort 10 for generating Zn vapors communicates through the opening 18 with a filtering chamber 14 filled with refractory material *a* which is sepd. from the condensing chamber 15 by a perforated wall 16. 21, 22 are supports for holding the filter and condenser in position at the mouth of the retort.

Briquetting zinc ores. O. KIPPE. U. S., 1,168,401, Jan. 18. A soln. of Mg, Zn, Ca or Fe sulfate or chloride is used to moisten Zn ore mixed with "blue powder" or "Zn ashes or trimmings" and the solvent is evapd. after pressing the material into briquets.

Heating metal billets with powdered coal as fuel. W. P. BARBA. U. S., 1,167,472, Jan. 11. Powdered coal used for heating billets or other metal articles is mixed before use with about 2-5% of CaCO_3 to raise the m. p. of the ash produced so that it may adhere to the articles and form a protective coating on them and avoid production of scale.

Heating metals with powdered coal. W. P. BARBA. U. S., 1,167,471, Jan. 11. About 2-4% of powdered refractory clay is added to powdered coal before burning in furnaces containing billets or metal to be forged in order to raise the m. p. of the ash formed and avoid production of scale on the metal.

Heating metals with powdered coal. W. P. BARBA. U. S., 1,167,470, Jan. 11. About 2% of SiO_2 is added to powdered coal to be burned in furnaces, for heating metal billets, to combine with alkalis in the coal and minimize the formation of scale on the billets.

Apparatus for recovering metals and ammonia from solutions. F. L. WILSON. U. S., 1,167,460, Jan. 11. Ammoniacal liquors obtained in the treatment of ores of Zn, Cu or Ni with NH_3 and CO_2 are passed through the app. continuously and heated to effect distn. and recovery of NH_3 and pptn. of the metals as carbonates and hydroxides.

Protecting iron or steel against rust. W. H. ALLEN. U. S., 1,167,966, Jan. 11. Fe or steel articles to be rust-proofed are immersed in a soln. containing about 3% of $\text{Ca}(\text{H}_2\text{PO}_4)_2$ and carrying also about 0.4% of $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$, while passing air through the soln., until a layer of ferrosferric phosphate is formed.

Alloy-coated iron or steel. CLAYTON MARK, JR. and CLARENCE MARK. U. S., 1,168,663, Jan. 13. Fe or steel articles are coated with an alloy of Pb 92, Sb 4.5 and Zn 3.5% to protect them from corrosion. A bright hard coating of good resistance to acids is produced, which does not easily flake or peel off.

Coating iron or steel with lead alloy. CLAYTON MARK, JR. and CLARENCE MARK. U. S., 1,168,664, Jan. 18. Fe or steel articles are dipped into a molten alloy of Pb 86-98, Sn 1-8 and Zn 1-6% which is protected by a layer of NH_4Cl flux containing Zn and Fe. The bath is maintained at a temp. of 400-500°.

Copper alloy for edge tools. W. C. PEASE. U. S., 1,168,962, Jan. 18. Cu is alloyed with Al 6.6, Fe 1.96, Sb 1.26 and Si 1.6%, to harden it. The Sb may be omitted, using the Si 0.74; Al 3.08 and Fe 1.80%.

Electric resistance alloy. M. A. HUNTER. U. S., 1,168,074, Jan. 11. An alloy is formed of Cu 5-25, Ni 75-95 and Cr 10-25 parts, the preferred proportions being 15:85:20, resp.

Alumino-thermic mixture. J. H. DEFFELER. U. S., 1,168,061, Jan. 11. In welding by alumino-thermic mixts., a body of added metals is placed in a container sheet of Fe or other fusible material which is preheated with the mold used in welding and is then allowed to unite with the molten metal produced by the alumino-thermic mixt.

Welding different metals. H. SEIDLER. U. S., 1,168,752, Jan. 18. A casing of molten Cu is poured around a core of steel or other metal of higher m. p. than the casing metal, the 2 metals are heated to the welding temp. and are allowed to cool so that the contraction of the casing metal on the core effects a firm weld.

Welded gold-silver plate. C. J. THORP. U. S., 1,168,441, Jan. 18. Sheets of Au and Ag are fused together, one upon the other, to form a composite plate with Au on one face and Ag on the other, for use in density for making crowns, etc.

10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

Hugo Schiff. ANON. *Chem. Ztg.* 40, 37-8(1916).—Died Sept. 8, 1915. An obituary. J. H. MOORE.

Precipitation of quinine salts in saline solutions. FRANCESCO LENCI. *Giorn. farm. chim.* 64, 154-60(1915).—L.'s results confirm those obtained by Tarugi (d. C. A. 8, 2687). E. J. C.

Condensation of chloromethyl ether with α -alkylacetoacetic esters. ARTHUR LAPWORTH AND BENJAMIN S. MELLOR. Manchester. *J. Chem. Soc.* 107, 1273-80 (1915).— CH_2ClOMe in dry Et_2O reacted with $\text{AcNaMeCO}_2\text{Me}$ to form *methoxy-methoxy- β -methoxy- α -methylcrotonate*, $\text{MeOCH}_2\text{OCMe:CMcCO}_2\text{Me}$, b. 113°, rather stable towards concd. KOH and NaHSO_4 , and without action upon PhNHNH_2 , from which the corresponding *free acid* (A), feathery crystals or flat needles from petroleum, m. 72°, was obtained by very gradual hydrolysis with KOH in MeOH. When heated (A) loses CO_2 with the formation of small amts. of HCO_2H and of *γ -methoxymethoxy- Δ^2 -butylene*, $\text{MeOCH}_2\text{OCMe:CHMe}$, b. 183-5°, readily adding 1 mol. Br, and yielding HCHO when heated with mineral acids. When heated with H_2O at 150° in sealed tubes for 5 hrs., (A) lost CO_2 and formed HCHO and EtCOMe . Very similarly $\text{AcNa}(\text{CH}_2\text{Ph})\text{CO}_2\text{Me}$ reacted with CH_2ClCOMe to form *ethyl methoxy- β -methoxy- α -benzylcrotonate*, $\text{MeOCH}_2\text{OCMe:C}(\text{CH}_2\text{Ph})\text{CO}_2\text{Et}$, viscid oil with pungent odor, b. 174-5°, devoid of all ketonic properties, absorbing Br, and decolorizing KMnO_4 . The corresponding *free acid* (B), needles, m. 108°, which when heated gives rise to

CO_2 , γ -methoxymethoxy- δ -phenyl- Δ^8 -butylene, b. $238-40^\circ$, and small amts. of HCO_2H . H_2O acting upon (B) at 150° causes the loss of CO_2 and the formation of $\text{PhCH}_2\text{CH}_2\text{COMe}$. The Me ester of (A) readily condensed with $\text{AcCH}_2\text{CO}_2\text{Me}$ or $\text{AcCH}_2\text{CO}_2\text{Et}$ in the presence of ZnCl_2 and Ac_2O to form cryst. products. $\text{AcCH}_2\text{CO}_2\text{Et}$ led to the formation of a substance ($\text{C}_{12}\text{H}_{16}\text{O}_8$?), which could not be readily purified, but $\text{AcCH}_2\text{CO}_2\text{Et}$ yielded the compound $\text{C}_{11}\text{H}_{16}\text{O}_8$, m. $88-8.5^\circ$, readily changing to a gummy mass on exposure to air and having either 1 OCH_2OMe or 2 MeO groups (as shown by the Zeisel no.). All attempts to obtain definite hydrolysis products of this compd. were unsuccessful.

LOUIS E. WISE.

Rotatory power and refractivity. II. Rotatory powers, refractivities, and molecular solution volumes of camphor, bromocamphor, and ethyl tartrate in certain solvents. DAVID H. PRACOCK. Nobel's Explosive Factory, Ardeer, Ayrshire. *J. Chem. Soc.* 107, 1547-67 (1915); cf. *C. A.* 9, 749.—Using Livens' equation for $[\alpha]$ per unit length of solns. (cf. *C. A.* 7, 2896), P. deduces the following equation connecting rotatory power and refractivity: $r'p^2a(n^2-1)(n^2-1+1/a)/2 = [\alpha]$, where r' = const. arising from a term in Livens' equation, p is the frequency of the light employed, and a is a const. which can be calcd. from the equation $[\alpha_1]/[\alpha_2] = (n_1^2-1)(n_1^2-1+1/a)/(n_2^2-1)(n_2^2-1+1/a)$. The above equation does not take absorption into account. In order to test the truth of the theoretical relationship by means of expt., P. has detd. the $[\alpha]_D^{25}$ and n_D^{25} (as well as the d_4^{25} and V_m) for varying concns. in the case of camphor in EtOH, acetone, AcOEt, PhH, PhCl and iso-BuOH; of solns. of bromocamphor in EtOH, acetone, AcOEt, PhH; and of Et tartrate in iso-BuOH and BuOH. The values for the expressions, $(n^2-1)(n^2-1+1/a)$ (expression (A)) and $(n^2-1)(n^2-1+1/a)/[\alpha]_D$ (expression (B)) were found for all the concns. studied. According to the above equations, as long as the $[\alpha]_D$ of a substance remains of the same sign, in various solvents, the sign of expression (A) should remain unchanged. The value for expression (B) for a given series of solns. should remain const. provided the variation of $[\alpha]_D$ with concn. is due to variations in the velocity of light within the medium. P. finds, however, that in certain cases there are inconsistencies between the theory and the exptl. facts, possibly due to such factors, as absorption, which have not been considered. In very many other cases there is a close agreement between $[\alpha]$ and the "refractive expression." In general, camphor solns. showed a rather close agreement for the relation between rotatory power and refractivity. Camphor, in PhH, however, gave somewhat excessive variations in the value of expression (B), suggesting the possibility of the effect of PhH absorption bands. The curves for $[\alpha]_D$ of camphor in acetone and AcOEt resemble each other very closely, and the refractive expressions are also in very good agreement. The relation between $[\alpha]_D$ and refractivity are somewhat closer in the bromocamphor series than in the camphor series. Here the values for expression (B) of the EtOH and acetone solns. are practically identical, although $[\alpha]_D$ of the 2 series show marked variation, a fact which points to the change in the optical properties of the medium, and not to the deformation of the bromocamphor mol. In the case of Et tartrate in iso-BuOH and in BuOH, the general connection between $[\alpha]_D$ and n fails to hold. A minimum of $[\alpha]_D$ was noted in both cases (cf. Patterson, *J. Chem. Soc.* 79, 47 (1901)). Camphor in iso-BuOH also fails to show the usual connection between $[\alpha]_D$ and n . This indicates that the above effects are in part characteristic of iso-BuOH. The limitations of the methods used, the errors in calcg. the values of consts. and the discrepancies between theory and exptl. data are discussed. All data are tabulated, curves have been drawn whenever possible, and the derivations of equations are indicated.

LOUIS E. WISE.

Thermal decomposition of hydrogenated hydrocarbons. DAVID T. JONES. Eskmeals, Cumberland. *J. Chem. Soc.* 107, 1582-8 (1915).—Cyclohexane (A), methyl-

cyclohexane (B) and 1,4-di- and 1,2,3,4-tetrahydronaphthalene, (C) and (D), resp., were thermally decompd. in contact with porous porcelain. The decompns. were carried out in a hard glass bulb, constructed to allow complete air exhaustion prior to the introduction of the hydrocarbon, and to permit heating in an electric furnace. A manometer attachment registered the first signs of expansion, and the heating was continued at a temp. slightly above that at which the decompn. began, until expansion had practically ceased. After cooling, the gaseous products were quant. removed by means of a Sprengel pump and analyzed in a Bone and Wheeler gas analysis app., the absorbants being H_2SO_4 to remove PhH and the olefins with more than 3 C atoms; $\text{Ag}(\text{NH}_3)_2\text{Cl}$ to remove C_2H_2 and $\text{MeCH}:\text{CH}_2$. H was detd. by treatment with oxidized Pd; CH_4 and C_2H_4 were detd. by explosion methods. Decompn. of (A) was effected at 500° , the compn. of the resulting mixt. being approx. as follows: 26.1% PhH and higher olefins, 0.2% C_2H_2 , 8.5% C_2H_4 , 40.3% H, 3% CH_4 , and 21.9% C_2H_6 , the latter value being too high owing to undecompd. (A). (B) decompd. at 530° , yielding 12.8% C_6H_6 and C_8H_{10} , traces of C_2H_2 , 10.6% C_2H_4 , 42.1% H, 22.5% C_2H_6 , and 12% C_3H_8 . (C) decompd. at 420° , yielding a large amt. of C_{10}H_8 and a mixt. of 85.4% H and 14.6% CH_4 , with traces of C_8H_{10} . (D) heated at 530° yielded 3.3% PhH and C_8H_{10} , 3.5% C_2H_4 , 80.2% H, 9% CH_4 , and 4% C_2H_6 . The app. used in the decompn. is described in detail. The results are contrasted with those of other investigators in the field of thermal decompn. (cf. Haber, *Ber.* 29, 2691(1896), and Thorpe and Young, *Proc. Roy. Soc.* 21, 184(1873)), and the mechanism of the decompn. of H is briefly discussed.

LOUIS E. WISE.

Coumarin condensation. BIMAN B. DRY. *Imp. Coll. Sci., South Kensington. J. Chem. Soc.* 107, 1606-51(1915).—D. has studied the reactions of a number of phenols with $\text{OC}(\text{CH}_3\text{CO}_2\text{H})_2$ (A) and with various β -ketonic esters. An investigation of the action of $\text{CH}_3(\text{CO}_2\text{Et})_2$ upon phenols in the presence of EtONa showed that coumarin-acetic acids were the condensation products. The literature relating to similar coumarin condensations is reviewed in detail (cf. especially, Pechmann, *Ber.* 17, 929, 1646, 2187(1884); 32, 3681, *et al.*). In the presence of concd. H_2SO_4 , α -naphthol and (A) condense to form 1,2, α -naphthapyrone-4-acetic acid, $\text{C}_{10}\text{H}_6\text{O}.\text{CO}.\text{CH}:\text{CCH}_2\text{CO}_2\text{H}$ (B), appearing

in 2 modifications: a yellow cryst. powder (deposited by the original condensation mixt.), m. $212-3^\circ$, and slender, yellow plates, m. 181° . Both forms when heated above their m. ps. evolve CO_2 and yield 4-methyl-1,2, α -naphthapyrone. (B) gives a pale yellow *monosilver salt*, but after heating with alkali, neutralizing and adding AgNO_3 , the Ag salt of the corresponding naphthylglutaconic acid was formed. The following derivs. of (B) were prepd.: *ethyl ester*, long, prismatic needles, m. 139° ; *anilide*, short needles with a greenish tint, m. 264° (with charring); *amide*, prisms, m. 262° . The nitration of (B) in glacial AcOH with the subsequent addition of H_2SO_4 gave rise to 6-nitro-1,2, α -naphthapyrone-4-acetic acid, yellow nodules from glacial AcOH , m. 212° , with the evolution of CO_2 , and the formation of 6-nitro-4-methyl-1,2, α -naphthapyrone (C), nodular masses from $\text{C}_6\text{H}_5\text{N}$, m. 236° (also formed by the nitration of 4-methyl-1,2, α -naphthapyrone). When boiled with aq. NaOH , (C) was converted into *sodium β -4-nitro-1-hydroxy-2-naphthylcrotonate*, red, prismatic needles, which, when decompd. with cold HCl , yielded the *free acid*, 2,4-($\text{HO}_2\text{CCH}:\text{CMe}$)(O_2N) $\text{C}_{10}\text{H}_7\text{OH}$, m. $128-30^\circ$ (decompn.). On oxidation with KMnO_4 , (C) gave rise to 1,4,2- $\text{C}_{10}\text{H}_6(\text{OH})(\text{NO}_2)\text{CO}_2\text{H}$, m. 214° (cf. König, *Ber.* 23, 807(1890)). On reduction with SnCl_2 , (C) was converted into the corresponding *amino derivative*, lustrous, yellow needles from PhNO_2 , m. 243° , whose *hydrochloride*, prisms, decomp. $276-8^\circ$; *acetyl derivative*, needles, m. $277-8^\circ$; *benzoyl derivative*, long needles, m. $261-2^\circ$. P_2S_5 acting upon 4-methyl-1,2, α -naphthapyrone in xylene, gave rise to 2-thio-4-methyl-1,2, α -naphthapyrone

(D), yellow microprisms, with metallic green reflex, from glacial AcOH, m. 187°, which when heated in PhH with HgO was converted into the original pyrone. (D) in alc. reacted with HONH₂ to form *4-methyl-1,2,α-naphthapyrone oxime*, C₁₀H₈O.C(:NOH).CH:CMc, soft, yellow needles, m. 235°. The Et ester of (B)

gave rise to *ethyl 2-thio-1,2-α-naphthapyrone-4-acetate*, golden yellow needles from glacial AcOH, m. 146°. (A) and β-naphthol reacted to form *4,3-β-naphthapyrone-1-acetic acid* (E), C₁₀H₆C(CH₂CO₂H):CH.CO.O, freshly pptd., m. 202-3°; if recrystd. from

alc., yellow needles, m. 191°, and changing into 4,3-β-naphthapyrone. The colorless silver salt of (E) is formed in cold neutral soln. If (E) is boiled in aq. NaOH for several hrs., the soln. neutralized with HNO₃ and AgNO₃ added, pale yellow *disilver β-2-hydroxy-1-naphthylglutaconate* is formed. The *ethyl ester of (E)*, plates, m. 164°; *methyl ester*, pale yellow plates, m. 187°. (E), after boiling with 16% aq. NaOH, formed *β-2-hydroxy-1-naphthylglutaconic acid*, yellow powder, m. 174° (with the formation of CO₂ and 1-methyl-4,3-β-naphthapyrone) and reconverted into (E) on attempted recrystn. from alc. or other solvents. *2-Thio-1-methyl-4,3-β-naphthapyrone*, yellow needles, with green reflex, m. 199°, and *1-methyl-4,3-β-naphthapyrone oxime*, lemon-yellow needles, m. 197°, were both prepd. by methods analogous to those previously outlined. By treating 1-methyl-4,3-β-naphthapyrone in boiling AcOH with Cl, or by condensing β-naphthol with AcCH₂CO₂Et, D. obtained *2-chloro-1-methyl-4,3-β-naphthapyrone* (F), prismatic needles, m. 135°. When (F) in alc. was heated with concd. aq. KOH, and the soln. acidified D. obtained *α-chloro-β-2-hydroxy-1-naphthylcrotonic acid*, HOC₁₀H₆CMc:CCICO₂H, plates, m. 148° and reverting into (F), possessing an aromatic odor. With similar treatment, 4,3-β-naphthapyrone yielded *β-2-hydroxy-1-naphthylcrotonic acid*, HOC₁₀H₆CMc:CHCO₂H, mica-shaped plates, m. 146°, possessing an aromatic odor. Et 4,3-β-naphthapyrone-1-acetate, when heated in concd. H₂SO₄ for 1 hr. at 120-30° and the product poured into cold H₂O, deposited 5-hydroxy-2-keto-*peri-peri-naphthindenofurane* (I), soft, yellow needles with greenish reflex, m. 280-2°

(charring). Its *sodium salt*, orange-red prisms, becoming purple on exposure to light. *Acetate*, short, yellow needles, m. 211-2°, fluorescing in alc. *Benzoate*, soft needles, from alc., m. 207°; *methyl ether*, m. indefinitely, 224-9°. 7-Hydroxycoumarin-4-acetic acid (G) (cf. Burton and Pechmann, *Ann.* 261, 167 (1891)) formed by the method outlined above yields the *disilver β-2,4-dihydroxyphenylglutaconate*, yellow ppt. Et ester (H) of (G), needles, m. 157°, not 134° (as given by P.), was prepd. by condensing *m*-(HO)₂C₆H₃ with NaHC(CO₂Et)₂ in abs. alc. The *acetate* of (H), needles, m. 124°; *benzoate*, needles, m. 126°; *methyl ester* of (G), silky needles, m. 122°; *methyl ether* of (G), prisms, m. 187°, with evolution of CO₂ and formation of 7-methoxy-4-methylcoumarin, m. 159° (cf. P. and Duisberg, *Ber.* 16, 2125 (1883)). The *ethyl ester* of the Me ether of (G), aggregates of radiating needles, m. 105°. On chlorination in AcOH, (G) formed the 3,6,8-trichloro derivative, m. 246° with evolution of CO₂ and formation of 3,6,8-trichloro-7-hydroxy-4-methylcoumarin (cf. Fries and Lindemann, *C. A.* 8, 1744). The tri-Cl acid, when boiled under reflux for 4 hrs. with 20% alc. KOH and

the soln. acidified, yielded 4,6-dichloro-5-hydroxy-1-carboxycoumarone-2-acetic acid, $\text{Cl}_2(\text{HO})\text{C}_6\text{H}_2\text{O}(\text{CO}_2\text{H})\text{:CCH}_2\text{CO}_2\text{H}$, m. 256-7°, yielding a cryst. silver salt. Quinol

reacted very feebly with (A), but condensed with the Et ester of (A) to form ethyl 6-hydroxycoumarin-4-acetate, fern-like needles, m. 174-6°. Catechol and (A) reacted to form a very small quantity of 8-hydroxycoumarin-4-acetic acid, needles, m. 228-30°. 7-Methylcoumarin-4-acetic acid (cf. Fries and Volk, C. A. 5, 1411) forms an anilide, blunt needles, m. 250°; a 3,6-dichloro derivative, plates, m. 231-2°, with the formation of 3,6-dichloro-4,7-dimethylcoumarin. A poor yield of 6-methylcoumarin-4-acetic acid, needles, m. 181°, was obtained, by the usual procedure, from 4-MeC₆H₄OH. The ethyl ester, silky needles, m. 131°; anilide, powder, m. 242-3°; 3-chloro derivative, fine, silvery needles, m. 163-4°, which, on boiling with alc. KOH, formed 1-carboxy-4-methylcoumarone-2-acetic acid, needles, m. 244°; silver salt (not characterized). Ethyl 8-methylcoumarin-4-acetate, microneedles, m. 114°, formed by treating o-cresol and (A) with abs. alc. and H₂SO₄, gave rise to the free acid, needles, m. 184°, with evolution of CO₂ and formation of 4,8-dimethylcoumarin, soft needles, m. 118°. Orcinol was the mother substance of 5-hydroxy-7-methylcoumarin-4-acetic acid (J), needles, m. 260-5°, passing into the anhydride (not characterized), on drying at 150-60°. (J) yields silver β-2,6-dihydroxy-p-tolylglutaconate, when treated by the usual method. Ethyl ester of (J), pale yellow, silky needles, m. 219°, forming a cryst. sodium derivative, an acetyl derivative, needles, m. 139°, and a benzoyl derivative, plates, m. 165°. The methyl ether of the methyl ester of (J), slender prisms, m. 133°, the mother liquor from which, upon acidification, yielded the methyl ether of (J), needles, m. 205°. Alk. KMnO₄ oxidized (J) to p-orsellinic acid, m. 166-8° (decompn.) (p-orsellinic acid prepd. from orcinol m. 162-4°, and the mixt. of acids m. 162-4°). o-4-Xylenol readily condensed with (A), forming 6,7-dimethylcoumarin-4-acetic acid (K), powder, m. 213-4° (when freshly pptd.), but m. 198° (decompn.) when crystd. from alc., passing, when heated, into 4,6,7-trimethylcoumarin, m. 169°. Ethyl ester of (K), needles, m. 145°; anilide, needles, m. (charring), 259-60°; 8-nitro derivative of (K), yellow needles, m. 189-90°; 3-chloro derivative, oblong plates, m. 194-6°. 2-Thio derivative of the Et ester of (K), prepd. by the usual method, reddish yellow needles, m. 156°. The following pyrogallol derivs. were synthesized: 7,8-Hydroxycoumarin-4-acetic acid, hard needles, m. 214-5°, showing daphnetin color reactions, and decompg. into β-methyl daphnetin (cf. P. and Cohen, Ber. 17, 2188(1884)); ethyl ester (L), prismatic needles, m. 191°; anilide, microcrystals, m. 270-2° (decompn.). (L) in dry acetone, when oxidized with an excess of PbO₂, formed ethyl 7,8-diketocoumarin-4-acetate (II), scales, from petroleum-PhH mixts., m. 170-5°, reducing NH₂-AgNO₃, converted by alkalis and H₂SO₄ into the original coumarinacetic acid. Methyl 7,8-dimethoxycoumarin-4-acetate, woolly needles, m. 139°, is readily hydrolyzed by alkalis into the corresponding free acid, sandy, cryst. powder, m. 179°. 6,7-Dihydroxycoumarin-4-acetic acid (from hydroxyquinol), short prisms, m. 214° with evolution of CO₂ and the formation of 4-methylesculetin (P. and Krafft, Ber. 34, 423(1901)). Its ethyl ester, needles from acetone, m. 214°. 5,7-Dihydroxycoumarin-4-acetic acid (1 mol. H₂O) (prepd. from phloroglucinol), m. 204-5°, forming an internal anhydride, C₁₁H₆O₆ (m. p. not given), when heated at 140-50°. From 4-ClC₆H₄OH, D. obtained 6-chlorocoumarin-4-acetic acid, slender needles, m. 182° with conversion into 6-chloro-4-methylcoumarin. Ethyl ester, silky needles, m. 167°. 6-Chloro-m-cresol was the mother substance of 6-chloro-7-methylcoumarin-4-acetic acid, flakes, m. 206° with the formation of 6-chloro-4,7-dimethylcoumarin, m. 213° (also formed from ClMeC₆H₄OH and AcCH₂CO₂Et). 3-Me₂NC₆H₄OH and the Et ester of (A) gave rise to ethyl 7-dimethylaminocoumarin-4-acetate, slender, colorless prisms, m. 133°, giving an intensely bluish violet fluorescence in alc., which disappears on addition of acid. On careful hydrolysis the ester yields

the *free acid*, yellow needles, m. 168°, giving rise to the corresponding coumarin, m. 145°. More vigorous hydrolysis of the ester with hot alkali causes scission of the coumarin ring. The following were products obtained by condensing $\text{EtO}_2\text{C.COCH}_2\text{CO}_2\text{Et}$ with phenols: (from *p*-cresol) *ethyl 6-methylcoumarin-4-carboxylate*, needles, m. 155–7°; *free acid*, m. 208–10°; (from *p*- $\text{ClC}_6\text{H}_4\text{OH}$) *ethyl 6-chlorocoumarin-4-carboxylate*, bright yellow needles, m. 96–7°; *free acid*, pale yellow needles, m. 224°; (from 6-chloro-*m*-cresol) *ethyl 6-chloro-7-methylcoumarin-4-carboxylate*, golden yellow needles, m. 117°; *free acid*, powder, m. 246°; (from *m*-cresol) *ethyl 7-methylcoumarin-4-carboxylate*, pale yellow needles, m. 94–6°; *free acid*, m. 200°; (from β -naphthol) *ethyl 4,3- β -naphthapyrone-4-carboxylate*, prisms, m. 138° (cf. Bartsch, *Ber.* 36, 1968(1903), who failed to obtain this product); *free acid*, m. 256°. Condensation between phenols and $\text{AcCHClCO}_2\text{Et}$ (prepd. by a slight modification of Allihn's method, *Ber.* 11, 569(1878)) gave rise to the following compds.: (from *p*-cresol) *3-chloro-4,6-dimethylcoumarin*, long needles, m. 160°, quant. converted by alc. KOH into 2,4-dimethylcoumarilic acid, m. 224°; (from *m*-cresol) *3-chloro-4,7-dimethylcoumarin*, prismatic needles, m. 135°, converted into the corresponding coumarilic acid by alc. alkali; (from *o*-4-xenol) *3-chloro-4,6,7-trimethylcoumarin*, needles, m. 170°, converted by alc. alkali into 2,4,5-trimethylcoumarilic acid, needles, m. 249–50° (decompn.), which was changed into the corresponding coumarone, m. 41° (cf. Störmer, *Ann.* 312, 300(1900)) when distd. with lime; (from phloroglucinol) *3-chloro-5,7-dihydroxy-4-methylcoumarin*, yellow needles, m. 306–8° (decompn.); *dimethyl ether*, needles, m. 170°; *diacetate*, silvery needles, m. 154°; *dibenzoate*, rhombic plates, m. 187°; (from hydroxyquinol) *3-chloro-6,7-dihydroxy-4-methylcoumarin*, needles, m. 259°; *diacetate*, needles, m. 172°; *dibenzoate*, flat, slender needles, m. 193°; (from α -naphthol) *3-chloro-4-methyl-1,2- α -naphthapyrone*, long, stout needles, m. 225–7°, quant. converted into α -naphthafurane-1-carboxylic acid when heated with alc. KOH. The following are derivs. of $\text{EtO}_2\text{C.COCHClCO}_2\text{Et}$: (from *m*-cresol) *ethyl 3-chloro-7-methylcoumarin-4-carboxylate*, sharp needles, m. 154°, yielding, with alc. KOH, *5-methylcoumarone-1,2-dicarboxylic acid*, powder, m. 218–21°; (from *o*-4-xenol) *ethyl 3-chloro-6,7-dimethylcoumarin-4-carboxylate*, needles, m. 177°, giving rise to *4,5-dimethylcoumarone-1,2-dicarboxylic acid*, needles, m. 321–24°. The foregoing di- CO_2H acid on heating with lime probably formed 4,5-dimethylcoumarone, oil. The above hydroxycoumarins dissolve in cold alkali with a yellow color of varying intensity. On methylating the OH group or otherwise destroying the active H the coumarins produced dissolve in hot alkali without coloration. LOUIS E. WISE.

Displacement of the halogen in optically active phenylhalogenacetic acids by the anilino group. ALEXANDER MCKENZIE AND STANLEY C. BATE. Univ. St. Andrews, Dundee. *J. Chem. Soc.* 107, 1681–5(1915).—*dl*-(PhNH)PhCHCO₂H (A) (cf. Knoevenagel, *Ber.* 37, 4084(1904), *et al*) was prepd. both from *dl*-PhCHClCO₂H (B) and *dl*-PhCHBrCO₂H by reaction with PhNH₂ under varying conditions. The following is a convenient method for the prepn. of (A): 1 mol. of (B) was heated for 6.5 hrs. on the H₂O bath with 4.4 mols. of PhNH₂. An excess of 2 *N* NaOH was added, the unchanged PhNH₂ removed with steam and (A) pptd. by means of aq. HCl. (A) crystd. from C₆H₆ in leaflets, m. 174–5° after drying *in vacuo*. (The data quoted in the literature regarding the m. p. are discordant.) Re-resolution of (A) was effected by means of the cinchonine salt. An equimol. mixt. of (A) and cinchonine in EtOH deposited *cinchonine l-phenylanilinoacetate*, glassy needles, not obtained c. p., which, after treatment with NH₄OH, followed by acidification with dil. H₂SO₄, yielded the *free l-acid* (C), m. 188°, [α]_D (acetone) –117.9°, (EtOH) –111.7°, (AcOEt) –106.8°. *l*-PhCHClCO₂H (D), when heated with 9.5 mols. of PhNH₂ in aq. NaOH, yielded a partially racemized *d*-(PhNH)PhCHCO₂H, [α]_D 25°. When the *d*-isomer of (D) was similarly treated, a partly racemized (C) was obtained. Less racemization was

noted when the reaction between (*D*) and PhNH_2 was carried out in dry PhH . Direct heating of (*D*) with PhNH_2 , with or without the subsequent addition of NaOH , yielded a very feebly *d*-rotatory anilido acid. A much less racemized acid was obtained ($[\alpha]_D^{25}$ 92.5° and 99°) by condensing *l*- $\text{PhCHBrCO}_2\text{H}$ with PhNH_2 in aq. alkali or in dry PhH . (*C*) undergoes partial racemization when treated with aq. alkali, the racemization increasing with the concn. of the base. Parallel control expts. showed that alkali had a much greater racemizing effect on (*C*) than had aq. alkali.

LOUIS E. WISS.

Experiments on the Walden inversion. X. Displacement reactions with *l*-phenylbromoacetic acid. ALEXANDER MCKENZIE AND NELLIE WALKER. Univ. St. Andrews, Dundee. *J. Chem. Soc.* 107, 1685-1701(1915); cf. *C. A.* 7, 2548.—A study of the Walden inversion with *l*- $\text{PhCHBrCO}_2\text{H}$ (*A*) was undertaken in order that 2 acids of the types *CabcCl* and *CabcBr* might be contrasted. (For data relating to the *Cl* acid, cf. *C. A.* 2, 2236; 3, 2963; and Senter, *C. A.* 9, 2520.) The resoln. of *dl*- $\text{PhCHBrCO}_2\text{H}$ was effected as follows: To 63 g. morphine in 900 cc. MeOH were added 90 g. of the *dl*-acid. Crystn. was then allowed to proceed during 6 hrs. (longer time periods possibly favoring partial elimination of the *Br*). The resulting morphine salt was decompd. with cold aq. H_2SO_4 , the product extd. with Et_2O , the exts. dried over Na_2SO_4 , allowed to evap. spontaneously, and the residue recrystd. 4 times from light petroleum. (*A*) thus obtained in 15 g. yield sepd. in large glistening leaflets, m. 87-8°, $[\alpha]_D^{15.6}$ -147°, $[\alpha]_{441}$ -178.2°. Modifications of the resoln. method resulted in the formation of $\text{PhCHBrCO}_2\text{H}$ mixts. of varying $[\alpha]_D$. The action of H_2O upon (*A*) at room temp. led to the formation of $\text{PhCH(OH)CO}_2\text{H}$, $[\alpha]_D$ 4.7°. The rates of racemization of a 1% aq. soln. of (*A*) were detd. at 25° and at 36.8°, and compared with the rates of *Br* displacement ("hydroxylation") at the same temps. The former were followed polarimetrically, while the hydrolysis consts. were detd. by withdrawing aliquots of the soln. at intervals, titrating with 0.025 *N* alkali, and deducing *k* from the usual equation for a unimol. reaction. The comparative data, tabulated and graphically represented, shows that racemization progresses more rapidly than does *Br* displacement. During the course of the above expts. the gradual development of a very slight but distinct *d*-rotation was at times noted, after the racemization reaction had apparently proceeded to completion. McK. and W. suggest the following explanation of the action of H_2O upon (*A*): An initial formation of *dl*- and *l*- $\text{PhCH(OH)CO}_2\text{H}$ (*B*) is followed by a slight reaction in the opposite direction, between HBr and (*B*), resulting in the formation of *d*- $\text{PhCHBrCO}_2\text{H}$ which is rapidly transformed into a mixt. of *dl* and *d*- $\text{PhCH(OH)CO}_2\text{H}$. A quant. study of the action of a mixt. of equal vols. of acetone and H_2O upon (*A*) also showed that the velocity of racemization was appreciably greater than the rate of hydroxylation. *Morphine l*-phenylbromoacetate, prisms(?) very sparingly sol. in the common solvents, was formed by the addition of 1 mol. of (*A*) to 0.5 mol. of morphine in MeOH . After boiling this salt for 2 hrs. with 113 parts H_2O , an optically inactive $\text{PhCH(OH)CO}_2\text{H}$ was isolated. Data and curves comparing the action of aq. NaOH and of H_2O upon the *Na* salts of (*A*) indicate that the rate of racemization is more rapid when alkali is present. The increased rate of racemization is probably due to the action of NaOH upon the $\text{PhCH(OH)CO}_2\text{H}$ formed by hydrolysis. NH_4OH acting upon (*A*) gave a mixt. of *dl* and *d*- $\text{PhCH(NH}_2\text{)CO}_2\text{H}$ (crystd. from H_2O), $[\alpha]_D$ 97.4°. The mother liquor further yielded a $\text{PhCH(NH}_2\text{)CO}_2\text{H}$, $[\alpha]_D$ 149.3° (cf. Fischer and Weichhold, *Ber.* 41, 1286(1908)). The filtrate from this crop when acidified and extd. with Et_2O yielded a *l*-mandelic acid, $[\alpha]_D$ -55.8°. When NH_3 is passed into (*A*) in dry PhH and the mixt. acidified, a mixt. of $\text{PhCHBrCO}_2\text{H}$, m. 73-87°, $[\alpha]_D$ -28.6°, was obtained. The action of a number of compds. upon (*A*) resulted in the formation of varying $[\alpha]$. The following is a list of

the reacting compds., the $[\alpha]_D$ of the resulting mandelic acid obtained in each case being given in the parentheses: Ag_2CO_3 (95.3°); AgNO_3 (62°); Ag_2O (84.8°); HgNO_3 (37.4°); $\text{Hg}(\text{NO}_3)_2$ (21°); HgO (19.1°); PbO (13.7°); $\text{Pb}(\text{OH})_2$ (5.8°); $\text{Pb}(\text{NO}_3)_2$ (5.3°); CuSO_4 ($\approx 0^\circ$). MeONa and the Na salt of (A) gave a mixt. of *dl* and *l*- $\text{PhCH}(\text{OMe})\text{CO}_2\text{H}$, $[\alpha]_D -61^\circ$, but when the Ag salt was substituted for the Na salt a *d*- $\text{PhCH}(\text{OMe})\text{CO}_2\text{H}$, $[\alpha]_D 54^\circ$, was obtained. Similarly MeONa and $\text{PhCHClCO}_2\text{H}$ gave a mixt. of *dl* and *l*- $\text{PhCH}(\text{OMe})\text{CO}_2\text{H}$, $[\alpha]_D -40.3^\circ$, whereas $\text{PhCHClCO}_2\text{Ag}$ yielded a *d*-acid, $[\alpha]_D 40^\circ$.

LOUIS E. WISZ.

Semicarbazones. V. Semicarbazones of benzaldehyde and some of its substitution products. JAMES A. R. HENDERSON AND ISIDOR M. HILBRON. Royal Tech. Coll., Glasgow. *J. Chem. Soc.* 107, 1740-52(1915).—Continuation of previous work on the semicarbazones (*C. A.* 9, 604). A number of semicarbazones have been spectrographically examd., and the formation of their unstable hydrochlorides has been investigated. *p*- $\text{MeC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$ absorbs dry HCl , forming an unstable, yellow salt containing approx. 1.5 mols. HCl . *Salicylaldehyde semicarbazone dihydrochloride*, yellow, unstable in air; *monosulfate*, straw-yellow, decomp. 150° , fairly stable in air. *o*-*Methoxybenzaldehyde semicarbazone*, needles, m. 215° (decompn.); *dihydrochloride*, dark orange, fairly stable in air. *p*- $\text{HOC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$ (A) (cf. Borsche and Bolser, *Ber.* 34, 2098(1901), who obtained a yellow compd., m. $223-5^\circ$; and Knöpfer, *Monatsh.* 31, 72(1910), who prepd. a white substance, m. 218°) was obtained as colorless needles, m. 222° (decompn.); *dihydrochloride*, yellow, unstable; *monosulfate*, yellow. A small amt. of (A) was obtained in the form of a yellow isomer, but was apparently converted into the stable, colorless compd. on crystn. from hot alc. *p*-*Methoxybenzaldehyde semicarbazone* was obtained in 2 modifications: yellow prisms, m. 168° (sol. in acetone), and colorless needles, m. 209° (decompn.), insol. in acetone (previously prepd. by Knöpfer, *et al.*, m. $203-4^\circ$). The *dihydrochloride* is a very unstable, orange-yellow salt. The *monosulfate*, mustard-yellow, decompd. 152° , and was stable in air. Orange-yellow *vanillin semicarbazone dihydrochloride*, decomp. 78° , was very unstable in air, melted to a dark red liquid, which dried to form a pale yellow solid. *Veratraldehyde semicarbazone dihydrochloride*, dark orange-yellow, unstable in air, began to m. 90° , decompd. 130° . *Piperonal semicarbazone dihydrochloride*, orange-red salt, unstable in air, decompd. 110° . *2-Hydroxy-m-methoxybenzaldehydesemicarbazone*, needles, m. 225° (decompn.); *dihydrochloride*, yellow, unstable, m. 158° (decompn.); *2,3-dimethoxybenzaldehyde semicarbazone*, needles, m. 231° (decompn.); *dihydrochloride*, dirty yellow salt, unstable. *o*-, *m*- and *p*- $\text{ClC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$, colorless, m. $229-30^\circ$, 230° , and $232-3^\circ$, resp. (previously prepd. by Law and Perkin, *C. A.* 2, 3336, who give $225-6^\circ$, 228° and 230° , resp.). A small quantity of a yellow form of *o*- $\text{ClC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$, prisms, m. 146° , was also isolated. The *hydrochloride* of the *o*-compd., cream-colored, unstable, decompd. 203° ; the *m*-*hydrochloride*, colorless, unstable, decompd. 198° ; the *p*-*hydrochloride*, unstable, pale yellow, decompd. 182° . *o*-, *m*- and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$ (cf. Thiele and Stange, *Ann.* 283, 25 (1894), who give the m. p. of the *p*-compd. as 221° , whereas H. and H. find 211°) yielded, resp.: a *hydrochloride*, cream-colored, unstable, decomp. 212° ; *hydrochloride*, cream-colored, unstable, decomp. 222° ; *hydrochloride*, pink, fairly stable, not decomp. 275° . *o*-*Acetoxybenzaldehyde semicarbazone*, granular powder, m. 167° ; *dihydrochloride*, dark yellow salt, unstable in air. *o*-*Benzoyloxybenzaldehyde semicarbazone*, needles, m. $195-6^\circ$; *dihydrochloride*, cream-colored, unstable. *2-p-Nitrobenzoyloxybenzaldehyde*, pale yellow leaflets, m. 128° ; *semicarbazone*, pale yellow needles, m. 218° (decompn.); *monohydrochloride*, unstable in air. *p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{CH}:\text{NNHCONH}_2$ (B) yielded a hydrochloride of indefinite constitution, containing more than 3 mols. HCl , very unstable. Spectrographic investigation showed that with 2 exceptions the above semi-

carbazonones in 0.0001 *N* alc. soln. showed a band at about $1/\lambda$ 3500, (*B*) and $p\text{-O}_2\text{NC}_6\text{H}_4\text{CH:NNHCONH}_2$ being the exceptions. When the semicarbazone contains a OH group, the addition of EtONa causes a shift in the position of the absorption band towards the red. When the H of the OH group is displaced by Me, the addition of EtONa causes no change in the position of the band. (*B*) in alc. showed the same absorption curve as $p\text{-HOC}_6\text{H}_4\text{CH:NNHCONH}_2$ in EtONa. The curves obtained for $o\text{-HOC}_6\text{H}_4\text{CH:NNHCONH}_2$ and its Me ether, and for 2-hydroxy-*m*-methoxybenzaldehyde semicarbazone and its Me ether show a band at about $1/\lambda$ 2600, in concd. H_2SO_4 , which is not present in the other curves.

LOUIS E. WISE.

Isomerism of the oximes. VII. 5-Bromovanillin oxime, 5-nitrovanillin oxime and 6-nitropiperonal oxime. OSCAR L. BRADY AND FREDERICK P. DUNN. *Imp. Coll. Sci. Tech.*, S. Kensington. *J. Chem. Soc.* 107, 1858-62 (1915); cf. *C. A.* 9, 603.—Realizing that certain negative groups in the PhH ring appear to favor the existence of isomeric oximes, B. and D. studied the effect of the introduction of negative substituents into vanillin oxime. 5-Bromovanillin (*A*) prepd. by direct bromination of vanillin in glacial AcOH, in the presence of AcONa, was converted into the oxime (*B*), needles, m. 179°. (*A*) could not be oxidized to the acid by CrO_3 in glacial AcOH nor by alk. KMnO_4 . (*B*) when boiled with Ac_2O for an hr. yielded 5-bromo-4-acetoxy-3-methoxybenzonitrile, m. 110-1°, which when heated for a few min. with dil. aq. NaOH formed the sodium derivative of 5-bromo-4-hydroxy-3-methoxybenzonitrile, plates. The latter yielded the corresponding nitrile, needles, m. 144°, which when hydrolyzed with 20% aq. NaOH formed 3,4,5-MeO(HO)BrC₆H₃CO₂H, m. 221° (cf. Robertson, *Ibid* 93, 792 (1908)). The diacetyl derivative of (*B*), cryst. powder from aq. alc., m. 122°, was formed by dissolving (*B*) in warm Ac_2O and decomp. with Na_2CO_3 , or by concn. of a mixt. of (*B*) and Ac_2O in vacuo over H_2SO_4 and Ca(OH)_2 . Hydrochloride of (*B*), m. 175° (decompn.). 5-Nitrovanillin oxime (*C*), orange-yellow needles, m. 216°; sodium salt, red needles, non-explosive but deflagrating slightly on rapid heating. With Ac_2O , (*C*) yielded a monoacetyl derivative (1 H_2O), orange needles, m. 147°; diacetyl derivative, cryst. yellow powder, m. 112°. The latter was more readily formed by treating (*C*) in $\text{C}_6\text{H}_5\text{N}$ with AcCl . The hydrochloride of (*C*), m. 204° (decompn.). 6-Nitropiperonal oxime (const. not given) yielded an acetyl derivative, yellow needles, m. 142°, but failed to form a hydrochloride.

LOUIS E. WISE.

Transition points of polymorphic phthalylhydrazides. FREDERICK D. CHATTAWAY AND WILLIAM J. LAMBERT. Oxford. *J. Chem. Soc.* 107, 1773-81 (1915).—Phthalylphenylhydrazide (*A*) exists in 2 enantiomeric forms, pale yellow orthorhombic plates and short, bright yellow, monoclinic crystals (cf. C. and Wünsch, *C. A.* 6, 1152). C. and L. have carefully detd. the soly. of the enantiomerides in EtOH and CHCl_3 , drawn 2 pairs of soly. curves, and noted the point of intersection (transition point) in each set of curves. The transition point (most accurately detd. in CHCl_3) lies at about 9.4°. The av. result of similar detns. in acetone and AcOEt was 9.5°. Phthalylphenylmethylhydrazide (*B*) exists as bright orange triclinic prisms, stable at higher temps., and compact, pale yellow, monoclinic crystals, stable at lower temps. Here the transition point was not readily detd. by the soly. method, but was shown to lie in the neighborhood of 55°. The point was very accurately detd. by the use of a dilatometer, which was packed with a mixt. of coarse crystals of the 2 forms, filled to a suitable height with a satd. soln. of (*B*) in acetone and placed in a const. temp. bath adjusted to about 55°. The dilatometer capillary was then sealed, and the temp. noted at which no increase or decrease in vol. occurred. The transition point was shown to be 55.1°. The transition point of (*B*), detd. by observing the growth of one form at the expense of the other, in a mixt. of enantiomerides covered with acetone, and noting the temp. at which no growth of either form could be detected, was shown to

be approx. 55.25°. Detailed tabulated data are given. C. and L. have also presented exptl. data in confirmation of van't Hoff's deduction (made in 1897-8) that the *ratio of solubilities of enantiomerides at a given temp. is independent of the solvent.* L. E. W.

3-gem-Dimethylpiperidine. JOHN J. G. M. DUNLOP. Cambridge. *J. Chem. Soc.* 107, 1712-3(1915).—This compd. was needed in an attempt to prep. a dicyclic quaternary NH_4 salt which should have no lateral sym. with reference to the N atom (cf. C. A. 7, 591). Of the various methods tried for the reduction of α,α -dimethylglutarimide, only that with Na in boiling AmOH gave 3-gem-dimethylpiperidine, b. 137°, smells like $\text{C}_6\text{H}_{10}\text{NH}$, best purified through the *chloroaurate*, needles, m. 182°; *hydrochloride*, very deliquescent; *hydriodide*, m. 200°, somewhat deliquescent; *benzoyl derivative*, needles, m. 68-9°. M. HEIDELBERGER.

A decomposition of certain *o*-nitromandelic acids. GERTRUDE M. ROBINSON AND ROBERT ROBINSON. Sydney. *J. Chem. Soc.* 107, 1753-62(1915); cf. C. A. 8, 3417.—3,4,6-(MeO)₃(O₂N)₂C₆H₃CHO and KCN in HOAc at room temp. for 3 days, followed by addition of H₂O, collection of the ppt. and hydrolysis with concd. HCl on the H₂O bath, gave 6-nitro-3,4-dimethoxymandelic acid, pale yellow needles, m. 169-72° (decompn.); 10 g. heated in 50 cc. PhNO₂ until the vigorous reaction commenced yielded 4,5,4',5'-tetramethoxyazobenzene-2,2'-dicarboxylic acid (A), glistening leaflets resembling hematite, m. 274° (decompn.), gives a blue color with H₂SO₄. Azoveratrole (B), when purified by recrystn. from EtOAc, m. 182°, not 163° (Kauffmann and Kugel, C. A. 5, 3813); in HOAc it gives with HNO₃ (d. 1.42) 2,2'-dinitro-4,5,4',5'-tetramethoxyazobenzene, orange needles, m. 315° (decompn.); this is also obtained by triturating (A) with HNO₃ and letting stand overnight, but differs in having a red color, due, presumably, to some isomorphous impurity, as no chem. or other phys. differences could be detected; reduced by shaking for a few days with Sn, SnCl₂, and concd. HCl, it forms 4,5-(H₂N)₂C₆H₃(OMe)₂ (C), isolated as the phenanthraphenazine, m. 259-61°, not 255° (Moureu, *Compt. rend.* 123, 33(1896)), and sol. in H₂SO₄ with a magenta, not violet color; it fluoresces violet in alc. or HPh. In HOAc with HNO₃ (d. 1.52) (B) gives a greenish yellow ppt. which redissolves to a red soln., which then yields *N*, 2,2'-trinitro-4,5,4',5'-tetramethoxyhydrazobenzene, probably RNHN(NO₂)R, yellow needles, m. 228°, gives an olive green soln., changing to blue, in warm H₂SO₄; forms (C) on reduction. 6,3,4-(O₂N)₃(CH₂O)₃C₆H₃CH(OH)CO₂H (which may be resolved through the brucine salt), when heated in PhNO₂, evolves some N, possibly due to the formation of Ph₂ compds. from the azo compd., giving a chocolate-colored mixt. from which, through the Na salt, was isolated 4,5,4',5'-dimethylenetetraoxyazobenzene-4,4'-dicarboxylic acid (D), brick-red needles, m. 270° (decompn.), sol. in H₂SO₄ with a blue color; when ground up with an excess of HNO₃ (d. 1.45) the purple liquid loses its color and yields a red ppt., which, after addition of H₂O, yields 2,2'-dinitro-4,5,4',5'-dimethylenetetraoxyazobenzene, crimson needles from PhNO₂, darkens 295°, decomps. 305°, gives a blue color in H₂SO₄; treated as in the case of the veratrole deriv. it yields 2,3-methylenedioxyphenanthraphenazine, also prepd. from 4,5-(O₂N)₂C₆H₃O₂CH₃, pale yellow needles, m. 305°, fluoresces blue-violet in HPh, sol. in H₂SO₄ with a magenta color. 20 g. 3,4-CH₂O₂C₆H₃CH₂OH, satd. at 0° in 100 cc. HOAc with HCl and then gradually treated with 30 cc. HNO₃ (d. 1.42), with cooling, gave, after standing 15 min. and pouring into H₂O, 6-nitrohomopiperonyl chloride, pale salmon-colored leaflets, m. 86°, powerfully irritating to the skin, but contains the Cl more firmly bound than in the untrated compd.; when boiled in PhNO₂ it gives (D) in poor yield; with cold MeOH-KOH it yields 2,2'-dinitro-4,5,4',5'-dimethylenetetraoxystilbene, brown-red needles, darkens 280°, but does not m. below 350°. M. HEIDELBERGER.

Monotropic polymorphic anilides. FREDERICK D. CHATTAWAY AND WILLIAM J. LAMBERT. Oxford. *J. Chem. Soc.* 107, 1766-73(1915).—Anilides cryst. in general

in 3 forms, which may be designated as the woolly, the needle, and the compact forms. It is now found that a large number of anilides may be made to cryst. in 2 of these forms, and some even in all 3. Both 2,4-Br₂C₆H₃NHAc (A) and 4-BrC₆H₄NHAc (B) have been observed by others to cryst. in 2 forms, but transformations of these forms have not been recorded. If these 2 anilides are crystd. from alc. needles first appear. These slowly redissolve, giving way to the compact form, it being necessary occasionally to seed the (A) solns. to cause the change. The rapidity of the change varies greatly with the solvent and with the compd. used, (A) requiring 6 months, 10 days, 5 days, and (B) 8 weeks, 24 hrs., 6 hrs., in 50% alc., abs. alc., and HOAc, resp., when chilled magmas of the needle form in test tubes were seeded with the stable form and allowed to stand. In CHCl₃ and HPh the change was so rapid on cooling that only the stable form could be detected. The rate of transformation increases rapidly with the temp., and is almost instantaneous just below the m. p. In both cases the compact form is the stable form between 0° and the m. p. The solys. of the 2 modifications of the 2 compds. were plotted graphically for the ranges of temp. in which the change was sufficiently slow, giving pairs of parallel curves, indicating that the compds. are monotropic. The solubilities of (A), (B), *p*-ClC₆H₄NHAc, 2,4-Cl₂C₆H₃NHAc, 4,2-ClBrC₆H₃NHAc, and 2,4-ClBrC₆H₃NHAc were detd. in EtOH between the temps. of 5° and 45°, and the results plotted in a series of curves. No general conclusions could be drawn from the curves. The solns. were weighed out in a pipet of special design, a plug of cotton wool below a constriction in the detachable stem serving to filter the soln. M. H.

Colorations produced by some organic nitro compounds with special reference to tetranitromethane. II. ALEXANDER K. MACBETH. Belfast. *J. Chem. Soc.* 107, 1824-7(1915); cf. *C. A.* 9, 1037.—A qual. examn. of the colors produced on adding C(NO₂)₄ to solns. of various unsatd. substances suggested that this might be used to indicate the amt. of residual affinity in the mol. of the substance tested, or to give a comparison of the reactivities of substances of the same or similar type. The following series of substances shows a progressively deepening set of colors from negligible to reddish brown: (CH₃)₂O, 1,4-dioxane, 1,4-thioxane (A), (CH₃)₂S (B), 1,4-dithiane (C), and MeN(CH₃)₄NMe. A study was made of the influence of the S atoms in (A), (B), and (C), by following the change in the absorption spectrum of the NO₂ compd., as given in paper I. In the case of (B) and (C) the penetrations of the band developed are nearly identical, and both are much greater than in the case of (A). These results agree with Clarke's (*C. A.* 7, 593) on the initial velocities of the S atoms in these substances with BrCH₂Bz. Another point of interest developed is that the presence in the unsatd. mol. of electronegative atoms or conjugated linkages exerts an inhibitive action on the production of color with C(NO₂)₄. This is illustrated by a number of examples. In aromatic substances, however, the conjugated linkages do not inhibit the coloration. Solvents exert a pronounced effect; petr. ether and, to a lesser degree, CHCl₃ hinder the "nitrite isomerization" to which the development of color is attributed, and H₂O accelerates it. Diagrams of the absorption spectra obtained are given. M. HEIDELBERGER.

Methoxyl determination in compounds containing sulfur. ALFRED KIRPAL AND THEODOR BÜHN. *Monatsh.* 36, 853-63(1915).—In the pyridine method the H stream earlier recommended (*C. A.* 8, 2163) can be replaced by a CO₂ stream. The method gives good results with methylimide detns. but cannot be used for EtO detns. The ordinary Zeisel method may be used as follows: CdSO₄ soln., heated to 60°, is placed before the AgNO₃ soln. This absorbs the H₂S and pptts. it as CdS. With this method EtO groups can also be detd. C. J. WEST.

Hydrolysis product of dimolecular isovaleryl cyanide and a new preparation of isobutyltartronic acid. JOSEF PLATTNER. Univ. Innsbruck. *Monatsh.* 36, 899-910

(1915).—20 cc. $(\text{Me}_2\text{CHCH}_2\text{CO})_2\text{O}$ and 9 g. KCN were allowed to stand 24 hrs., the K salt pptd. with a large vol. of Et_2O and the soln. concd., giving an oil which would not cryst. Upon hydrolysis with a mixt. of 70 g. concd. H_2SO_4 and 10 g. H_2O , this yields *dimolecular isovalerylformamide*, $\text{Me}_2\text{CHCH}_2\text{C}(\text{CONH}_2)_2\text{OCOCH}_2\text{CHMe}_2$, leaflets, m. 167° . With dil. HCl (d. 1.1) the diamide gives isobutyltartronic acid, m. 107° . *Lead, silver, barium salts*. *Phenylhydrazine salt*, cryst. powder, m. 136° . If the dicyanide is hydrolyzed with a mixt. of 70 g. concd. H_2SO_4 and 5 cc. H_2O , *isovalerylformamide*, $\text{Me}_2\text{CCH}_2\text{COCONH}_2$, is the principal product, tables, m. 60° . Upon hydrolysis with HCl this yields α -ketocaproic acid, isolated as the *silver salt*, cryst., and the *phenylhydrazone*, long needles.

C. J. WEST.

Dibutyramide and dipropyltriazole and its salts. W. MILLER. Univ. Innsbruck. *Monatsh.* 36, 929–39 (1915).—Dibutyramide is best prepd. by treating $(\text{C}_4\text{H}_7\text{O})_2\text{O}$ with small amts. of KCNO at 120° (oil bath temp.), waiting until the CO_2 evolution ceases before another lot is added. When CO_2 is no longer evolved the diamide is filtered off and the filtrate again treated with KCNO. 1 mol. diamide and 2 mols. $\text{H}_2\text{NCONHNH}_2\cdot\text{HCl}$ react to give 1 mol. *hydrazodicarbonamide*, separated by its insoly. in water, m. 246° , and 1 mol. *dipropyltriazole*. Better yields are obtained by using $\text{Ca}(\text{C}_4\text{H}_7\text{O})_2$ to neutralize the HCl formed. *Silver salt*, $\text{C}_8\text{H}_{14}\text{N}_2\text{Ag}$. *Mercury salt*, $2(\text{C}_8\text{H}_{14}\text{N}_2\text{HgCl})\cdot 2(\text{C}_8\text{H}_{14}\text{H}_2\text{HgCl}\cdot\text{HCl})\cdot\text{HgCl}_2$. *Hydrochloride*, octahedrons, m. 133° .

C. J. WEST.

p-Chloro- and *p*-bromo-*m*-cresols. II. R. F. VON WALTHER AND K. DEMMELMEYER. *J. prakt. Chem.* 92, 107–32 (1915); cf. C. A. 9, 2641.—The sulfonation of *p*-chloro-*m*-cresol (a) has been previously conducted simply as a means of sepg. (a) from its isomers; the acid itself was not identified (cf. Liebrecht, Ger. pat. 233,118). *6*-Chloro-3-hydroxy-1-methylbenzene-4-sulfonic acid (b) is formed when (a) is slowly added to an equal wt. of H_2SO_4 (d. 1.84) at 70° and then sufficiently heated to keep in a molten condition (there is no tendency to form a di- SO_3H acid either with H_2SO_4 or ClSO_3OH). (b) seps. from H_2O or concd. HCl in leaves with 2 mols. H_2O . On rapid heating it m. 93° , but when heated slowly it m. as low as 75° (decompn.). Though readily decompd. at 100° into (a) and H_2SO_4 , it is stable toward boiling dil. NaOH or boiling 10% HCl. Cl is not removed on reduction with Na and alc.; PCl_5 fails to give an acid chloride. Its Na salt was not esterified when treated with MeI or Me_2SO_4 . On nitration the SO_3H group is split off with the formation of the dinitro-*p*-chloro-*m*-cresol which m. 68° . The *sodium salt* of (b) is pptd. by Na_2CO_3 ; it is difficultly sol. in cold H_2O and seps. from hot H_2O in leaves (100 cc. H_2O at 14° dissolves 1.82 g. salt). (b) is not liberated by dil. acids from solns. of its Na salt. *Disodium salt*, from (b) and concd. NaOH, small needles; *potassium salt*, 4 H_2O , leaves from H_2O ; *neutral barium salt*, leaves; *calcium salt*, 2 H_2O , clusters of microscopic needles; *silver salt*, prisms from H_2O ; *ammonium salt*, elongated prisms, difficultly sol. in cold H_2O ; *aniline salt*, from (b) and $\text{PhNH}_2\cdot\text{AcOH}$, prisms from H_2O . *Di-p-chloro-m-cresyl carbonate* (c), pptd. on passing COCl_2 into the alk. soln. of (a), seps. in long silk-like threads from ligroin, m. 141° ; heated at 215° with dry NaOEt in a H atm. (c) is converted into *p*-chloro-*m*-cresyl Et ether and Et *p*-chloro-*m*-cresotinate. The yield of the latter is small. *Methyl p-chloro-m-cresyl carbonate*, from (a) and ClCO_2Me with the calcd. quantity of NaOH, oil, b. 135° . *Ethyl p-chloro-m-cresyl carbonate*, b. 148° . *p*-Chloro-*m*-cresoxyacetic acid (d), obtained in good yield from (a) and $\text{ClCH}_2\text{CO}_2\text{H}$ according to the method of Giacosa (*J. prakt. Chem.* 19, 396), prisms from H_2O , m. 176° ; *sodium salt*, needles from H_2O ; *potassium salt*, silk-like threads from H_2O ; *ammonium salt*, leaves from H_2O ; *calcium salt*, long prisms from H_2O ; *barium salt*, small leaves from H_2O ; *silver salt*, clusters of needles from H_2O ; *copper salt*, blue needles in clusters from 75% alc.; *lead salt*, needles from dild. alc.; *methyl ester*, by action of dry HCl on the

MeOH soln., leaves from petr. ether, m. 37°; *ethyl ester*, leaves from petr. ether, m. 32°. *6-Chloro-4-nitro-3-cresoxyacetic acid* (e), from (d) heated at 100° with concd. HNO₃ for several hrs., clusters of light yellow, slender needles or threads from H₂O, m. 155°; concd. HNO₃ has only a slight action on (d) in the cold. A di-NO₂ compd. was not obtained on treating (d) with concd. HNO₃ + Ac₂O. When treated with Na₂S₂O₄, (e) is not reduced to the corresponding NH₂ compd., but is converted into

3-keto-6-chloro-7-methyl-1,4-benzoxazine, $\text{MeClC}_6\text{H}_3\text{O.CH}_2\text{CO.NH}$, long needles from 70% alc. or 70% AcOH, m. 187°. By application of the Reimer and Tiemann reaction (a) is converted into *6-chloro-3-hydroxy-4-toluic aldehyde*, long, light yellow needles from petr. ether, 50% alc. or 50% AcOH, m. 68°. The yield is relatively large for this reaction. The *sodium salt*, deep yellow leaves, is very unstable. *6-Bromo-4-nitro-3-cresol* (f), from *p*-bromo-*m*-cresol (g) in AcOH with the calcd. amt. of dil. HNO₃ in the cold, deep yellow needles from 96% alc., m. 124°, volatile with steam. The *ammonium salt* seps. in bright orange-colored needles; *sodium salt*, red needles; *potassium salt*, dark red prismatic needles; *calcium salt*, bright orange leaves; *barium salt*, dark orange leaves from alc.; *silver salt*, dark red needles. *6-Bromo-2,4-dinitro-3-cresol* (h), from (g) nitrated with 2 mols. dil. HNO₃ without cooling, bright yellow leaves from 50% AcOH, m. 111°, non-volatile with steam; *ammonium salt*, small orange needles; *sodium salt*, bright orange needles; *potassium salt*, orange needles; *calcium salt*, long, orange prisms from alc.; *barium salt*, bright yellow needles; *silver salt*, orange needles. *6-Bromo-4-amino-3-cresol*, formed in good yield by reduction of (f) with Na₂S₂O₄, leaves from H₂O, unstable when moist, m. 116°. *6-Bromo-3-hydroxy-1-methylbenzene-4-sulfonic acid* (i), produced under the same conditions as (b), seps. from hot concd. HCl soln. in small iridescent leaves containing 2 mols. H₂O and m. (not sharply) 103–125°; *ammonium salt*, long prisms from H₂O; *sodium salt*, leaves from hot H₂O; *potassium salt*, stout prisms; *calcium salt*, leaves from H₂O; *barium salt*, long prisms; *silver salt*, leaves from H₂O; *aniline salt*, hexagonal prisms from H₂O. On nitration (i) is converted into (h) with replacement of —SO₃H. The following derivs. of (g) were also prepd.: *Di-p-bromo-m-cresyl carbonate*, prismatic leaves from alc., m. 130°. *Methyl p-bromo-m-cresyl carbonate*, b₁₈ 158°. *Ethyl p-bromo-m-cresyl carbonate*, b₁₇ 167°. *p-Bromo-m-cresoxyacetic acid* (j), prismatic leaves from 50% AcOH, m. 178°; *sodium salt*, prismatic needles from H₂O; *potassium salt*, prismatic leaves from H₂O; *ammonium salt*, needles from H₂O; *calcium salt*, prisms; *barium salt*, leaves from H₂O; *silver salt*, needles; *lead salt*, needles; *copper salt*, blue cubes; *methyl ester*, leaves from petr. ether, m. 36°; *ethyl ester*, leaves from petr. ether, m. 46°. *6-Bromo-4-nitro-3-cresoxyacetic acid*, obtained by heating (j) with concd. HNO₃ and Ac₂O, long, light yellow needles from H₂O, or bright yellow prisms from dil. AcOH, m. 177°; a di-NO₂ deriv. could not be isolated. Reduction produced a benzoxazine but the yield was too small to permit of identification. *6-Bromo-3-hydroxy-4-toluic aldehyde*, light yellow needles from 50% AcOH, m. 96°; the *sodium salt*, yellow leaves, is unstable.

NORMAN A. SHEPARD.

β-Hydroxy-β-phenylethylamine and related compounds. C. MANNICH AND E. THIELE. Univ. Goettingen. *Arch. Pharm.* 253, 181–95(1915).—The difficulties heretofore encountered in the reduction of aminoalkyl aryl ketones to the corresponding alcs. have been eliminated by the use of palladinized charcoal and H₂, thus rendering compds. of the type PhCH(OH)CH₂NH₂ available for synthetic investigation. Palladinized charcoal was prepd. by passing H through a suspension of powdered animal charcoal (previously freed from Fe by extn. with HCl) in a soln. of PdCl₂, the dried product containing about 2% Pd. The method of starting point in the present investigation was the mixt. of BzC BzCH₂NH₂.HBr resulting

from the action of hexamethylenetetramine on BzCH_2Br (cf. *C. A.* 5, 3237). On satn. with H in the presence of the above catalyst, the new base sepd. from the concd. filtrate as the carbonate which was then changed into the *hydrochloride*, m. 211° . β -Hydroxy- β -phenylethylamine, $\text{PhCH}(\text{OH})\text{CH}_2\text{NH}_2$, glistening needles, m. about 40° , was obtained by treating the hydrochloride with NaOEt , and found to be more stable toward alkali and acid than adrenaline. The Bz deriv., $\text{PhCH}(\text{OH})\text{CH}_2\text{NHBz}$, m. 146° (cf. Rosenmund, *Ber.* 37, 2483(1904); also *C. A.* 7, 2553), yields with Ac_2O and NaOAc the compound, $\text{PhCH}(\text{OAc})\text{CH}_2\text{NHBz}$, glistening needles, m. $112-3^\circ$. Other condensations effected were: with ClCO_2Et the derivative, $\text{PhCH}(\text{OH})\text{CH}_2\text{NHCO}_2\text{Et}$, scales, m. $87-8^\circ$ (cf. M. and Hahn, *C. A.* 5, 3237); with carbamide, β -hydroxy- β -phenylethylcarbamide, $\text{PhCH}(\text{OH})\text{CH}_2\text{NHCONH}_2$, crystals, m. 95° ; with $\text{Cl}_2\text{CHCO}_2\text{Et}$, phenyldichloroacetylaminomethylcarbinol, $\text{PhCH}(\text{OH})\text{CH}_2\text{NHCOCHCl}_2$, glistening leaves, m. 91° ; with $\text{CNCH}_2\text{CO}_2\text{Et}$, phenylcyanacetylaminomethylcarbinol, $\text{PhCH}(\text{OH})\text{CH}_2\text{NHCOCH}_2\text{CN}$, glistening needles, m. 111° ; with $\text{ClCH}_2\text{CO}_2\text{Et}$, the piperazine com-

pound, $\text{PhCH}(\text{OH})\text{CH}_2\text{N} \begin{array}{c} \text{CH}_2\text{CO} \\ \text{COCH}_2 \end{array} \text{NCH}_2\text{CHPhOH}$, cryst., m. 121° . Reduction

of $\text{MeOC}_6\text{H}_4\text{COCH}_2\text{NH}_2$ in concd. soln. yielded $p\text{-MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CH}_2\text{NH}_2$ (cf. Rosemund, *l. c.*), which gave the *benzoyl* compound, $\text{MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CH}_2\text{NHBz}$, feely needles, m. $151-2^\circ$, the latter forming the *acetate*, fine needles, m. 139° . Similarly were obtained the derivatives, $\text{MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CH}_2\text{NHCO}_2\text{Et}$, leaflets, m. 95° , and $\text{MeOC}_6\text{H}_4\text{CH}(\text{OH})\text{CH}_2\text{NHCONH}_2$, crystals, m. $122-3^\circ$. The hydrochloride (cf. M. and Hahn, *l. c.*), $\text{HOC}_6\text{H}_4\text{COCH}_2\text{NH}_2\cdot\text{HCl}$, prepd. by the action of HI on the MeO compd., gave on reduction β -hydroxy- β - p -hydroxyphenylethylamine hydrochloride, cryst. powder, m. 172° (decompn.); the free base, needles, m. $157-8^\circ$; the *dibenzoyl* derivative, leaflets, m. 215° ; the *O*-acetate, crystals, m. 170° .

W. O. E.

The Hofmann degradation of alkaloids of the phenanthrene (apomorphine) group. J. GADAMER. Univ. Breslau. *Arch. Pharm.* 253, 266-73(1915).—The scission of quaternary *N*-Me derivs. of methylated apomorphine, bulbocapnine and corytuberine to corresponding methine bases by means of hot concd. NaOH takes place in accordance with Formulas I and II. The theoretically possible formula (III) could not be con-

sidered in this connection from the fact that the isolated methine bases were optically inactive. It had already been shown by Klee (cf. *C. A.* 9, 298) in the case of isothebaine, which is quite similarly constituted, that both methine bases are simultaneously formed in about equal quantity and that the one constituted like Formula III possesses a

reverse optical activity to that of the mother substance. Scholtz (cf. *C. A.* 9, 2079) has likewise observed in the case of bebeerine the scission of methylisobebeerine methylhydroxide into an inactive α - and an active β -methine base. Degradation expts. carried out with Kondo on bulbocapnine Me ether in accordance with Kuntze's procedure reveal the fact that the methine base arising from boiling the *N*-Me ammonium base was optically active; that while bulbocapnine Me ether is *d*-rotatory, the methine base is strongly *l*-rotatory. G. and Kondo were able to prep. from the methine base, which heretofore had only been obtained in amorphous form, by soln. in MeOH a portion in cryst. optically active condition. In order to obtain the optically inactive methine base corresponding to Formula II in a pure state, the crude product was subjected to fractional satn. and Et_2O extn. After repeated attempts the inactive methine base (II), as well as the methine base (III), were isolated, the latter finally showing $[\alpha]_D = -270^\circ$. As subsequently shown by Kuntze, his former adverse findings resulted from the fact that he examd., not the crude product, but the pure methine bases prep'd. therefrom. Of the 2 methine bases obtained by such degradation, derivs. of the optically inactive form are the more difficultly sol. and more readily crystd. In former expts., the optically active constituent of the crude product always remained in the mother liquors. Kuntze was further able to show that the relative proportions in which the 2 bases are formed depends on the concn. of the soln., higher concns. favoring the formation of the optically active methine base. The methine base formed on heating dimethylapomorphine methiodide, which Pschorr failed to observe, is a mixt. of active and inactive compds. Likewise in the case of apomorphine, the resulting active methine base, which is obtainable in cryst. form, shows an opposite rotatory power (138.6°) to that of the mother substance. Similar conditions were found to obtain in the degradation of corytuberine, both dimethylcorytuberinemethines being formed. The hydrochloride showed $[\alpha]_D = -265^\circ$, the dimethylsulfate -220° to -225° . Tribenzoylcorytuberine was absolutely inactive. W. O. E.

Amber. A. TSCHIRCH AND CORNELIS DE JONG. Univ. Bern. *Arch. Pharm.* 253, 290-305 (1915).—A quantity of crude succinoabietic acid in 2 lots (designated A and B), isolated some 21 yrs. ago by Aweng, was treated according to T.'s extn. process and found to consist of a mixt. of substances. The available samples were dissolved in Et_2O (A yielding about 15%, B 10% insol. residue) and extd. with 1% $(\text{NH}_4)_2\text{CO}_3$.

The *succoxyabietic acid*, $\text{O.O.C}_{10}\text{H}_{19}\text{CO}_2\text{H}$, thus isolated and purified by means of the Pb salt, forms an amorphous powder, m. 120° , very sol. in alc., CHCl_3 , AcOH, acetone, $\text{C}_6\text{H}_5\text{N}$, $\text{C}_6\text{H}_{11}\text{OH}$ and MeOH, slightly sol. in cold, easily in hot C_6H_6 ; acid no. direct 147.21, indirect 151.80, sapon. no. cold 153.15, hot 174.18; I no. 18.60. The Et_2O soln. yielded to 1% Na_2CO_3 more than 50% *succinoabietinolic acid*, $\text{C}_{20}\text{H}_{30}\text{CO}_2\text{H}$ (purified via its Pb salt), amorphous powder, m. 112° (sample A) and 110° (sample B), very easily sol. in CHCl_3 , AcOH, acetone, $\text{C}_6\text{H}_5\text{N}$ and $\text{C}_6\text{H}_{11}\text{OH}$, easily sol. in cold alc., hot MeOH and C_6H_6 , acid no. direct 89.63, indirect 92.61, sapon. no. cold 97.03, hot 141.93, I no. 47.71. Treatment of the Et_2O soln. with 1% KOH developed the odor of borneol. HCl ppts. from the alk. liquid succinoabietinolic acid in the form of its borneol ester. Hydrolysis of the residue from the Et_2O soln. with 0.1 *N* KOH effects degradation in the succinoabietinolic acid as follows: $2\text{C}_{20}\text{H}_{30}\text{O}_2 + 2\text{H}_2\text{O} = 2\text{C}_{24}\text{H}_{38}\text{O}_2 + \text{C}_{20}\text{H}_{30}\text{O} + \text{C}_{10}\text{H}_{18}\text{O} + 2\text{H}_2\text{CO}_3$, the products thus being borneol, succinosilvic acid, succinoabietol and H_2CO_3 . *Succinoabietol*, $\text{C}_{20}\text{H}_{30}\text{O}$, amorphous powder, m. $90-1^\circ$, easily sol. in alc., Et_2O , acetone, CHCl_3 , insol. in petr. ether, identical with the product $\text{C}_{20}\text{H}_{30}\text{O}_2$ of Aweng. The Ac deriv. is sol. in petr. ether. *Succinosilvic acid*, $\text{C}_{24}\text{H}_{38}\text{O}_2$, amorphous powder, m. 104° , identical with Aweng's product. Quite similar results were obtained on a reexamn. of the alc.-sol. portion (about 30%) of amber. The alc.-insol. portion (about 70%), succinin, consisted principally of a resene, *succinoresene*, yellow amorphous

powder insol. in org. solvents, acids and alkalies. In addition to succinoresene, the alc.-insol. portion contains succinoresinol succinate which is hydrolyzed on treatment with 0.5 *N* KOH. *Succinoresinol*, $C_{12}H_{20}O$, m. 228° , is identical with Aweng's product.

Salt-forming power of natural chrysazin derivatives. O. A. OESTERLE AND E. R. HAUGSETH. Univ. Strassburg. *Arch. Pharm.* 253, 327-9(1915).—In cryst. rhein from C_2H_5N , Tisza observed (*C. A.* 3, 639) a retention of the solvent, which persisted even after washing with aq., alc. and ethereal acid solns. The present work follows closely along the lines of Pfeiffer's expts. (cf. *C. A.* 7, 3474) who found that certain hydroxyanthraquinones enter into combination with C_2H_5N to form salts. In the case of rhein, the salt, $C_{14}H_8O_2(OH)_2CO_2H.C_2H_5N$, was obtained, while frangula-emodin yields the compound, $C_{14}H_8O_2Me(OH)_2.C_2H_5N$, both of which lose their C_2H_5N on heating at $100-10^{\circ}$. No salts were obtained with chrysazin, chrysophanic acid and aloë-emodin, a behavior in perfect accord with the findings of Pfeiffer, who reported that only those hydroxyanthraquinones having OH groups in the β -position yield salts, α -hydroxyanthraquinones showing no such tendency.

W. O. E.

Certain derivatives of rhein. O. A. OESTERLE AND E. R. HAUGSETH. Univ. Strassburg. *Arch. Pharm.* 253, 330-4(1915); cf. *C. A.* 4, 1601.—On refluxing crude rhein chloride (cf. *Schweiz. Wochenschr.* 1911, No. 46) with C_2H_5OH , rhein propyl ester, $C_{14}H_8O_2(OH)_2CO_2C_3H_7$, was formed, yellowish brown needles, m. 145° , sol. in alc., Et_2O , $CHCl_3$, petr. ether, C_6H_6 , xylene and AcOH. The acetate, $C_{14}H_8O_2(OAc)_2CO_2C_3H_7$, resulted on treating the ester with Ac_2O and $AcONa$, yellow needles, m. 178° , insol. in cold dil. NaOH. Similarly, the following were prepd.: rhein isopropyl ester, yellowish brown crystals, m. 181° (acetate, light yellow needles, m. 190°); rhein isobutyl ester, yellow needles, m. 153° (acetate, yellow needles, m. 169°); rhein phenyl ester, yellow needles, m. 215° (acetate, yellow needles, m. 176°); rhein benzyl ester, could not be obtained in pure form (acetate, lemon-yellow, felty needles, m. 203°).

W. O. E.

The reactivity of α -hydroxyl groups in anthraquinones. O. A. OESTERLE AND E. R. HAUGSETH. Univ. Strassburg. *Arch. Pharm.* 253, 335-41(1915).—In the investigation of naturally occurring chrysazin (*a*) derivs., it has been repeatedly observed that the hydroxyls occupying α -positions show great differences in point of reactivity. In the methylation of chrysophanic acid (cf. *ibid* 243, 441(1905)), the introduction of the first Me group was effected without difficulty, while the di-Me ether was less easily prepd. and then only with indifferent yield. The behavior of (*a*) derivs. toward $ClCH_2CO_2Et$ is even more remarkable. Rhein (1,8-dihydroxyanthraquinone-3-carboxylic acid) reacts with 2 mols. $ClCH_2CO_2Et$, yielding the compd. $C_{14}H_8O_2(OH)(OCH_2CO_2Et)(CO_2CH_2CO_2Et)$ (cf. *C. A.* 4, 1601). Similarly, $ClCO_2Et$ reacts with salicylic acid to form the compd. $C_6H_4OCO_2Et(CO_2CO_2Et)$ (cf. Friedlaender, *Fortschr. Teerfarbenfabr.* 6, 146). An explanation for such variation in the behavior of apparently similarly situated hydroxyls is possibly found in a recent paper by Pfeiffer (cf. *C. A.* 7, 3474) in a study of color lakes. In the case of anthraquinones possessing α -(α)-hydroxyls, the assumption is made that the H of α -hydroxyls is in coördinate union with the carbonyl O ("innere Komplexsalzbildung") and is thus weakened in reactivity. According to this view (*a*) would present the following appearance:

from which it is seen that in chrysazin and its derivs. having hydroxyls in the α -position, one group first enters into reaction, the second group reacting only under exceptional conditions. Attempts made to prep. a di-K salt of (a) were unsuccessful, the only salt obtained being identical with the mono-K compd. reported by Woelbling (cf. *Ber.* 36, 2941 (1903)). $\text{ClCH}_2\text{CO}_2\text{Et}$ converts the K salt of (a) into the ester, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OH})\text{OCH}_2\text{CO}_2\text{Et}$, yellow needles, m. 198° , sol. in Et_2O , CHCl_3 , AcOH and C_6H_6 (acetate, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OAc})\text{OCH}_2\text{CO}_2\text{Et}$, canary-yellow needles, m. 144°). *Chrysazinmonoglycolic acid*, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OH})\text{OCH}_2\text{CO}_2\text{Et}$, yellow, hexagonal leaves, m. 236° . With Me_2SO_4 (a) yields the monomethyl ether, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OH})\text{OMe}$, orange-yellow needles, m. 198° (acetate, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OAc})\text{OMe}$, yellow needles, m. 208°). In addition to the mono-Me ether, which is also formed on treating the acetate with dil. NaOH the dimethyl ether, $\text{C}_{14}\text{H}_9\text{O}_7(\text{OMe})_2$, golden-yellow needles, m. 221° is obtained. W. O. E.

The reaction of levulose with diphenylamine. L. RADLBERGER. *Oesterr.-ung. Z. Zuckerind.* 44, 261-4 (1915).—Continuing the work of Kehrman and Micewiz (*C. A.* 7, 348) and Wieland and Müller (*C. A.* 8, 346), R. finds that the reaction between levulose and Ph_2NH occurs in 2 stages. The Ph_2NH is first converted to diphenylbenzidine by the H_2SO_4 , and then this is converted by the reduction of the levulose to *p*-diphenylquinonephenyldiimide, and indamine. Since on warming acid solns. of carbohydrates to 68° levulose or glucose is formed, the blue color reaction announced by Ihl (*Chem. Ztg.* 9, 451) as characteristic of all carbohydrates is, therefore, caused by either levulose or glucose, which, acting as oxidizers in the reaction in a similar manner, cannot easily be distinguished. E. A. TSCHUDY.

Structure of the dihydro- β -naphthoic acids. C. G. DERRICK AND OLIVER KAMM. *J. Am. Chem. Soc.* 38, 400-19 (1916).—The 3rd of the 3 possible dihydro- β -naphthoic acids with the unsatd. linkage in the same ring as the CO_2H group has been prepd. and it is shown that this new acid (a), m. 118° , is the Δ^1 , the "stable" acid (b), m. 161° , the Δ^2 , and the "labile" acid (c), m. 101.2° , the Δ^3 -compd. Incidentally, it was noticed that the amines of (a) and (b) and $\text{PhCH}:\text{CHCONH}_2$, m. 148° , all of which

contain the grouping $>\text{C}:\text{C}:\text{C}(\text{O})-$, have a marked cinnamon-like odor. The β - $\text{C}_{10}\text{H}_7\text{CO}_2\text{H}$ was obtained through the nitrile which, in turn, was prepd. by distg. the Na sulfonate with $\text{K}_4\text{Fe}(\text{CN})_6$ (yield, 120 g. from 62.5 g. salt) or the Ca salt with KCN (yield, 18 g. from 40 g. salt). Reduction with 3% Na-Hg in the cold in a stream of CO_2 to neutralize the alkali gives a mixt. of 75% (c) and 25% (b); in hot solns. the relative yields are 40 and 60%, resp. Sepn. is best effected by Baeyer's fractional pptn. method. Heated with excess of $\text{Ba}(\text{OH})_2$ or KOH at 160° in sealed tubes, both (b) and (c) yield the new acid (a), sometimes contaminated with some (b). Boiling of (c) 1 hr. with 10% KOH produces a partial rearrangement into (b) but no (a) is formed, but long boiling with more concd. (1:2) KOH can effect an almost complete rearrangement into (a). (a) seps. from dil. AcOH or alc. in needles whose solubility in various solvents is intermediate between that of (b) and (c); its ionization const. in H_2O at 25° is about 3.0×10^{-5} ; the solubility in H_2O ranges from 0.39 g. at 0° to 20.1 g. at $96-7^\circ$ in 10 cc. satd. soln., the corresponding values for (b) being 0.19 and 10.5 g. Its dibromide, from (a) and Br in cold CHCl_3 , m. 190° , that of (b) m. 210° and that of (c) (which does not decomp. spontaneously, as stated by Baeyer), m. 172° (all with decompn.). The dibromide of (c) dissolves in 5% soda but soon deposits in 80%

yield the lactone $\text{C}_9\text{H}_6\text{CH}_2\text{CH}(\text{CHBr})\text{CH}(\text{O})\text{CO}$, which, when boiled with 20% KOH , slowly dissolves with formation of $\text{C}_9\text{H}_6\text{CH}_2\text{CH}(\text{CO}_2\text{K})\text{CH}:\text{C}(\text{OH})$ (not isolated).

yielding on acidification the *keto acid*, $\text{C}_6\text{H}_4\text{CH}_2\text{CH}(\text{CO}_2\text{H})\text{CH}_2\text{CO}$, m. $143-5^\circ$, 1.5

g. of which dissolves in 1 l. of H_2O ; its *semicarbazone* m. 266° (decompn.). The dibromide of (b) decomps. smoothly, even at 0° , in 5% aq. soda or KOH into $\beta\text{-C}_{10}\text{H}_7\text{CO}_2\text{H}$ and HBr (90% yield). The dibromide of (a) in cold 5% KOH very quickly decomps. into the *acid* $\text{C}_6\text{H}_4\text{CH}(\text{OH})\text{C}(\text{OH})(\text{CO}_2\text{H})\text{CH}_2\text{CH}_3$, plates from Et_2O , m. 182° (yield,

65%), which is oxidized by KMnO_4 to $o\text{-HO}_2\text{CC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ (d). From 5 g. (a) in 75 cc. cold H_2O and 3 g. KOH treated in the course of 1 hr. with 6 g. KMnO_4 in 300 cc. H_2O is obtained an *acid* $\text{C}_6\text{H}_4\text{CO}\text{C}(\text{OH})(\text{CO}_2\text{H})\text{CH}_2\text{CH}_3$ or its hydrate

(found, neutral equiv. 210, C 60.5%, H 5.98%), m. $119-20^\circ$; 5 g. with 5 g. KMnO_4 gives 40% of (d).

CHAS. A. ROUILLER.

Structure of the dihydro- α -naphthoic acids. OLIVER KAMM AND HARRY B. MCCLUGAGE. *J. Am. Chem. Soc.* 38, 419-30(1916).—By reactions analogous to those used with the β -acids (preceding abstr.) it has been shown that the "stable" α -acid (a) is the Δ^1 - and the "labile" acid (b) the Δ^2 -compd. The 3rd possible Δ^2 -compd. has not been isolated thus far. (b), prepd. by Baeyer and Schoder's method (*Ann.* 266, 169(1891)), m. 86.5° after very careful purification (B. and S., 91°), ionization const. in 0.001 N soln. at 25° 11.52×10^{-5} ; 30 min. boiling with aq. 5% KOH suffices to rearrange it completely into (a), m. 121.5° (B. and S., 125°), ionization const. 7.96×10^{-5} . The ionization consts. agree well with those detd. for B. and S.'s products by Bethmann (*Z. physik. Chem.* 5, 399(1890)). Dibromide of (b), in 6.5 g. yield from 5 g. (b) and 5 g. Br in 15 cc. cold CHCl_3 (as the bromide is sol. in CHCl_3 it must be pptd. with several vols. of petr. ether), m. 125° . Dibromide of (a), in 7.6 g. yield from 5 g. (a), m. 151° (decompn.). The dibromide of (b) dissolves clear in 5% aq. KOH but in about 1 min. the soln. becomes slightly turbid, due to the sepn. of a small amt. of C_{10}H_8 ; the filtrate from this gives 85% of $\alpha\text{-C}_{10}\text{H}_7\text{CO}_2\text{H}$. The dibromide of (a), on the other hand, yields the *dihydroxy acid*, $\text{C}_{11}\text{H}_{12}\text{O}_4$, plates from Et_2O , m. 175° . In the hope of being able to synthesize the Δ^2 -acid, $1,4\text{-C}_{10}\text{H}_8(\text{OEt})\text{CO}_2\text{H}$ was reduced in hot alk. soln. with Na-Hg, but the EtO group was also reduced, the product being tetrahydro- α -naphthoic acid.

CHAS. A. ROUILLER.

Zingiberol—a new sesquiterpene alcohol occurring in the essential oil of ginger. BENJAMIN T. BROOKS. *J. Am. Chem. Soc.* 38, 430-2(1916).—B. has isolated from ginger oil (freed from terpenes and sesquiterpenes) citral, methylheptenone, nonylaldehyde, linalool, *d*-borneol, acetic and caprylic acids (as esters), a trace of a phenol (probably chavicol), cineol and a sesquiterpene alc., *zingiberol* (a), $\text{C}_{15}\text{H}_{26}\text{O}$, $b_{14.5}$ $154-7^\circ$ (24 g. from 150 g. oil), which imparts to the oil its peculiar persistent, though mild, ginger odor. Garnett and Greier's "gingerol" (*C. A.* 2, 447; 3, 2719) is a mixt. of (a) with a trace of a phenol. (a), heated with Ac_2O , gives only 17% ester, as calcd. from the sapon. no., and gives no phenylurethan with PhNCO after 4 days. With Na in dry Et_2O it readily forms a Na compd. and when gently heated with KHSO_4 it loses H_2O , forming zingiberene or isozingiberene, b. $255-7^\circ$, which with HCl in glacial AcOH yields the dihydrochloride, m. 169° ; the same salt is obtained from (a) and HCl in AcOH, while HBr gives the dihydrobromide, m. 176° (Semmler, *C. A.* 7, 2938).

CHAS. A. ROUILLER.

Some constituents of sumbul root. FREDERICK W. HEYL AND MERRILL C. HART. *J. Am. Chem. Soc.* 38, 432-46(1916).—An unsliced root from Moscow was used. Air-dried, it contained 10.2% moisture and 6.5% ash, Ligroin extd. 11.8%, Et_2O 14.6%, alc. 27.4%. The residue insol. in alc. contained 17.5% crude fiber, 10.6% pentosans, 3.4% protein, 7.7% starch, 1.4% dextrin; the alc. ext. showed 1.7% sucrose, approx.

1.0% levulose and 18.7% resin (after extg. hot); extn. with boiling 95% alc. removes 27.4% of the root while exhaustive percolation in the cold exts. only about 20%, 17.3% being pptd. by H₂O. The products sol. in cold alc. and in H₂O are, besides the above sugars, AcOH, an umbelliferone glucoside and betaine. The resin insol. in H₂O was extd. successively with ligroin, Et₂O, CHCl₃, AcOEt and alc. The ligroin ext. consisted of about 17% resinous material (other than fat), sol. in 1% KOH and yielding on hydrolysis vanillic acid and an oil resembling the volatile oil. The fat yielded a large amt. of indefinite unsaponifiable material, from which were isolated a fraction having approx. the compn. C₂₇H₄₈O and b₁₂ 168–73°, and a *phytosterol*, C₂₇H₄₈O, m. 134–5°; *acetate*, m. 121–2°. The fatty acids identified were acetic, butyric, valeric, tiglic, angelic, oleic, linoleic, cerotic, palmitic and stearic. The Et₂O ext. yielded a *phytosterolin*, C₂₈H₄₈O₆, m. 290° (*acetate*, m. 159–60°), and a trace of vanillin; it consists of 42% neutral and 52% acid resinous constituents; the former is an ester yielding umbelliferone (b), while the latter consists of a mixt. of resin acids yielding vanillic acid and (b) on hydrolysis. The CHCl₃ ext. consists largely of a resinous glucoside yielding (b) and glucose on hydrolysis. The AcOEt ext. was not a glucoside but gave (b) on hydrolysis, while the alc. ext. likewise yielded (b) and a reducing sugar on hydrolysis. Exptl. data are given in detail.

CHAS. A. ROUILLER.

Some derivatives of coumarin. FRANCIS D. DODGE. *J. Am. Chem. Soc.* 38, 446–57 (1916).—Coumarin (a) and limettin (b) with NaHSO₃ yield well-defined cryst. sulfonic compds. analogous to that obtained from esculetin by Rochleder (*J. prakt. Chem.* 101, 415 (1863); cf. also Liebermann, *Ber.* 35, 2919 (1902), and earlier papers). Thus, from (a) warmed 15–30 min. on the H₂O bath with 6 parts of 20% NaHSO₃ is obtained *sodium hydrocoumarinsulfonate* (c), crystals with 1 H₂O, sol. in about 5 parts of H₂O at 15°; the aq. soln. is neutral but at once reacts with alkali, neutralizing 1 mol., so that the compd. can be sharply titrated; if the soln. is concd. addition of a little 0.5 N alkali produces a transient ppt. of (a), which soon redissolves and the soln. becomes neutral again; further addition of alkali causes a repetition of the phenomenon until (a) ceases to sep. and the soln. remains permanently neutral; the soln. now does not contain the original (c), nor has the SO₃H group been split off, for the I absorption is negligible, but if the (a) pptd. by quickly adding alkali is filtered off before it redissolves, the filtrate is found to contain much sulfite. These facts are plausibly explained thus: (a) + NaHSO₃ = C₈H₆O.CO.CH(SO₃Na).CH₃ (c); (c) + NaOH =

(a) should therefore be sol. in Na₂SO₃ and as a matter of fact 10 g. (a) will dissolve in 100 cc. of 25% Na₂SO₃ after 3 days at room temp. and in 0.5 hr. at 100°, the soln. behaving in all respects like that obtained by titrating (c). *Potassium hydrocoumarinsulfonate*, from (a) and KHSO₃, needles with 1 H₂O; soly. in H₂O at 15°, 7.6%. *Barium salt*, from (c) and Ba(OAc)₂, cryst. ppt., sol. in about 44 parts H₂O at 20°. *Copper salt*, from (c) and CuSO₄, pale blue prisms. The soln. of *sodium hydrocoumarinsulfonate* (d) when highly concd. forms a viscous liquid solidifying in a desiccator to an indistinctly cryst. mass; the *barium salt*, prepd. by double decompn., seps. in not very sol. needles. With a large excess of alkali, (c) smoothly yields coumaric acid (e), about 10 g. being obtained by heating 10 g. (a) with 100 cc. of NaHSO₃ until dissolved, evapg. to about 50 cc., adding 40 g. of 50% KOH, evapg. to dryness on the H₂O bath, dissolving in H₂O and treating cold with concd. HCl. On the other hand, a soln. of (d) from 2 g. (a), when evapd. to dryness, powdered and allowed to stand 2 days with 5 cc. Ac₂O, yields (c), from which, working quickly and with ice-cold solns., 30 and 40% (a) can be recovered with NaOH and Ba(OH)₂, resp. This therefore gives the following cycle of reactions: (a) $\rightleftharpoons$ (c) $\rightleftharpoons$ (d) $\rightleftharpoons$ (e). (c) is also decompd. by alkali car-

bonates at room temp.; on adding concd. soda to a 20% soln. of (c), the liquid after a time becomes filled with fine crystals of (a) which, however, completely redissolve in a few hrs. (a) is apparently quant. regenerated from (c) at 130–60° according to the equation $2(c) = 2(a) + \text{Na}_2\text{SO}_3 + \text{SO}_2 + \text{H}_2\text{O}$. (b), a dimethoxycoumarin, also known as citraptene, yellow needles from Me_2CO , m. 148°, in the same way gives a sodium hydrolimettinsulfonate, plates with 4 H_2O (7.5 g. from 10 g. (b) gently boiled 0.5 hr. with 80 g. of 20% NaHSO_3 sol. in 6 parts H_2O at 20°; attempts to prep. a limetic acid analogous to (e) gave a non-crystallizable substance. (b) slowly dissolves in 25% Na_2SO_3 at 100° but no crystals can be obtained by salting out or evapg. the soln. The results of a few titrations of (a) and (b) immediately after heating with alc. KOH and at different time intervals thereafter, showing the progressive regeneration of the lactone, are reported. Although this lactone formation in alk. soln. is not strictly characteristic of coumarins, it is allowable to assume that in many cases where the phenomenon is observed some member of the coumarin series is probably present, as in the case of oil of bergamot and possibly of Gordin's "xanthoxylin" (*J. Am. Chem. Soc.* 28, 1649(1906)).

CHAS. A. ROULLIER.

Spectrophotometric study of copper complexes and the biuret reaction. PHILIP A. KOBER AND ARTHUR B. HAW. *J. Am. Chem. Soc.* 38, 457–72(1916); cf. *C. A.* 7, 3976; 9, 3252.—It has been found by K. and his colleagues that the Cu complexes of NH_2 derivs. and other similar substances can be divided into 3 classes: (1) blue, (2) purple or "semi-biuret," and (3) red or "biuret;" in (1) 2 N groups (amino, imino, imide or amide) are so placed that by forming "stable" rings they can combine with the Cu; in (2) there are 3 and in (3) 4 such groups. As the coordination no. of Cu is 4, in (2) an aquo or HO group is probably attached to the Cu besides the 3 N groups, and in (1) probably 2 HO groups are attached to the Cu. To establish the theory, it must be shown that the absorption spectra agree with the macroscopical observations and that it is really the N groups which produce the characteristic colors. The present paper deals largely with the 1st line of proof. In the ultraviolet the absorption is general and variations in the constitution of the complexes cannot be followed by quant. spectroscopy. In the visible spectrum the absorption curves were quant. detd. by means of a sector photometer and a high dispersion spectroscope on the basis of Talbot's law of rotating sectors. The results are probably accurate only to within 2%. The Cu complexes of 5 NH_2 acids and 4 dipeptides in neutral soln., of 5 tripeptides and 2 tetrapeptides in neutral, faintly alk. and strongly alk. soln., and of egg albumen, edestin, casein and biuret in strongly alk. soln. were studied and the results are reported in curves. The amt. and nature of the absorption of a given complex depends somewhat on the concn. of HO ions; in the tetrapeptides the red color is only faintly developed in the weaker alkali and more strongly in the more concd. alkali while the reverse is true for the tripeptides. There are 3 types of absorption curves: beginning at about 480, 459 and 443 $\mu\mu$, resp., with max. at 630, 540 and 505 $\mu\mu$. Diglycylglycine in faintly alk. soln. gives the semi-biuret color as strongly as the other tripeptides, Fischer's statement that it is an exception probably being due to the fact that he used strong alkali in making the biuret test. The protein complexes in strongly alkaline soln. give practically the same curves as tripeptides in faintly alk. soln. K. and H. conclude that the "biuret reaction" is no other than a complex formation with Cu and, as far as color formation is concerned, no decompn. of the protein is involved, and that the protein configurations are such that they permit only 3 N groups to form rings with Cu; therefore the protein mol. must be aggregated and is not in the form of long free chains or branches of peptides or conjugated NH_2 acids. Oxy or HO complexes of Cu, no matter what their configuration, are all blue or green, never red, and are characterized by their relative instability in alk. solns., and, on the other hand,

that red colors are due to N groups is indicated by the fact that substances possessing only N and no O give a red biuret reaction (diguandine copper); complexes containing a deficiency of O groups but sufficient N groups give a red biuret reaction; there is a great parallelism between the number of N groups available for combination with the Cu and the amt. of the red color.

CHAS. A. ROULLER.

The phosphoric acid in starch. JOHN H. NORTHPROP AND J. M. NELSON. *J. Am. Chem. Soc.* 38, 472-9(1916).—The P is chem. combined in the starch grains and cannot be extd. with dil. acid, either as free H_3PO_4 or in combination. The sample of potato flour used contained 0.06% P; no N could be found by the Kjeldahl or Dumas methods. Heated 14 hrs. on the H_2O bath with 10 parts of 10% HCl, all of the P is set free as H_3PO_4 , but when a paste of 10 kg. starch in 40 l. H_2O is treated with steam under 50 lbs. until completely liquefied, heated at 65° until it no longer gives a ppt. with alc., neutralized with solid $Ba(OH)_2$, filtered and pptd. with 2 vols. of 85% alc., there is obtained 60 g. of a white hygroscopic substance; 300 g. of this, treated with H_2SO_4 , $PbCO_3$ and H_2S , evapd. to a syrup under 25 mm. and pptd. with 8 l. of glacial AcOH yields 110 g. of a granular ppt. (the filtrate on concn. *in vacuo* and pptn. with alc. gives 75 g. of a yellowish powder with 3.4% P); the AcOH ppt. is a very hygroscopic powder, sol. in H_2O , pptd. by alc., contains 4.9% P (none as inorg. phosphates), no N, small amts. of MgO, sulfates, chlorides and SiO_2 , does not reduce Fehling soln.; benzoylation by the Schotten-Baumann method yields colloidal products from which, by pptn. from $CHCl_3$ or Me_2CO with ligroin, Et_2O , H_2O , etc., were obtained 2 amorphous substances containing 0.99-1.08 and 1.40-1.48% P, resp. $Pb(OAc)_2$, however, ppts. from the alc. soln. of the AcOH ppt. a *lead salt* const. in compn. under different conditions of prepn. (30.30-30.53% Pb, 3.78-3.99% P), which with H_2S yields the free acid as an extremely hygroscopic powder (5.24-5.56% P, 35.20-35.45% C, 5.84-5.93% H), reduces Fehling soln., $[\alpha]_D^{22}$ $108^\circ 30'$, gives on acid hydrolysis a reducing sugar equiv. to 65% glucose and yielding a heavy ppt. of glucosazone. The simplest formula conforming to the above analyses is $C_{17}H_{41}O_{16}(H_3PO_4)$. The % of Pb in the salt is greater than what it should be if the metal were combined only with the phosphoric acid (26.73%), but as the salt is formed in strong alc. soln., some of the Pb may be combined with the carbohydrate. The amt. of reducing sugar corresponds to 1 mol. maltose to 1 of phosphoric acid. The remainder of the mol. corresponds to $C_5H_8O_5$. No evidence of the presence of a pentose could be obtained but since difficulty was encountered in completely burning the substance in the analyses, owing to the presence of the H_3PO_4 , it is possible that the remainder of the mol. is a hexose. Since it does not reduce Fehling soln., it might be inositol or, if a hexose, so combined with H_3PO_4 as to destroy its reducing power. No inositol could be found in 8 g. of the crude material.

CHAS. A. ROULLER.

Stability of silver fulminate under water. ALFRED M. PETER. *J. Am. Chem. Soc.* 38, 486(1916).—A sample of the salt which had remained under H_2O in a bottle with a well greased stopper for some 40 years was found to be distinctly cryst. but of a mouse-gray color, owing to long exposure to light. Otherwise it showed no signs of change in physical or chem. properties.

CHAS. A. ROULLER.

Stereochemistry of the quinone oximes. VII. The mono-oximes of the 3-halogen-toluquinones. F. KEHRMANN, with F. MUSSMANN AND C. FACCHINETTI. Univ. Geneva. *Ber.* 48, 2021-6(1915); cf. *Ann.* 310, 89(1900).—As with the I compd. (*J. prakt. Chem.* 39, 397(1889)), so also 3-chloro- (a) and 3-bromotoluquinone (b) yield only mono-oximes, $OCMe:CH.C(:NOH).CH:CX$, and no dioximes. *Oxime of (a),*

from 10 g. (a) in 50 cc. alc. and a concd. aq. soln. of 1.5-2.0 mols. of $NH_2OH.HCl$ heated 15 min. on the H_2O bath, light yellow leaves, sol. in dil. alkalies with greenish yellow

color; heated a short time with Ac_2O and NaOAc , it yields an *acetate* sepg. from ligroin in 2 (probably stereoisomeric) forms: light yellow needles, m. 72° , and short thick, amber-yellow prisms, m. 62° ; only the former can be obtained pure, repeated crystn. of the latter always giving a mixt. of the 2 forms. With SnCl_2 and HCl , the oxime yields *aminochlorocresol*, 6,2,4- $\text{ClMe}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{OH}$, needles from C_6H_6 , m. 137° , turns brown in the air, while with HNO_3 (d. 1.1) at room temp. is obtained *nitrochlorocresol*, 6,2,4- $\text{ClMe}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{OH}$, light yellow prisms from ligroin, m. 122° . (b), from dibromo-*o*-cresol and $\text{Na}_2\text{Cr}_2\text{O}_7\text{-AcOH}$, orange-yellow needles from alc., m. 93.5° . *Oxime*, lemon-yellow leaves from C_6H_6 ; *acetate*, obtained in 2 forms, m. 74° and (impure) 71° , resp. *Aminobromocresol*, needles from C_6H_6 , m. 142° ; *hydrochloride*, needles yielding with Ac_2O an *acetate*, needles from C_6H_6 , m. 165° . *Nitrobromocresol*, lemon-yellow prisms from ligroin, m. 120.5° , identical with the product obtained from 2,4- $\text{Me}(\text{O}_2\text{N})\text{-C}_6\text{H}_3\text{OH}$ and 1 mol. Br_2 in a little AcOH at room temp. Heated on the H_2O bath with HNO_3 (d. 1.2) the oxime yields *dinitro-o-cresol*, 2,4,6- $\text{Me}(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{OH}$, yellow needles from alc., m. 85.5° . VIII. The dioxime of 4-chlorotoluquinone and the mono-oximes of 4,6-dichlorotoluquinone and of 3,6-dichlorotoluquinone. With GIUSEPPE SILVA and CORNELIUS KÉLETI. *Ibid* 2027-35; cf. *Ann.* 303, 1 (1898).—Both forms of 4-chlorotoluquinone mono-oxime, when boiled 24 hrs. in concd. alc. soln. with twice the calcd. amt. of $\text{NH}_2\text{OH.HCl}$, the HCl set free being neutralized from time to time with NaHCO_3 , yield the same *dioxime*, ill-defined light yellow cryst. kernels from alc. and AcOH , turns brown and decomp. about 240° ; addition of solid NaOH to the concd. reddish yellow alk. soln. ppts. a golden yellow *sodium salt* in thick prisms; boiling with excess of Ac_2O and NaOAc yields a *diacetate*, homogeneous, thick prisms from AcOH , decomp. about 185° . With $\text{SnCl}_2\text{-HCl}$ the dioxime gives 2,5-diamino-4-chlorotoluene *dihydrochloride*, converted by $\text{Ac}_2\text{O-NaOAc}$ into a *diacetyl derivative*, silky needles from alc. *Dinitrosochlorotoluene*, from the dioxime in dil. alk. soln. with $\text{K}_3\text{Fe}(\text{CN})_6$, lemon-yellow powder, decomp. about $163\text{--}5^\circ$, cannot be recrystd. without decompn., converted by reducing agents into the dioxime and then the diamine, while with concd. HNO_3 it gives the *dinitro compound*, thick, amber-yellow prisms from ligroin, m. 107° . When 4-chlorotoluquinone rubbed up with dil. HCl is treated with small portions of fuming HCl until the mass darkens and thickens and is then warmed on the H_2O bath until the cryst. magma is almost white, dild. with H_2O , filtered, dissolved in just enough boiling 50% AcOH and allowed to partially cryst., most of the trichlorotoluquinone formed can be removed; the filtrate on oxidation with cold Na_2CrO_4 yields 4,6-dichlorotoluquinone, golden yellow leaves from alc., m. $85\text{--}6^\circ$. *Oxime*, $\text{OC.CCl:CH.C(:NOH).CMe:CCl}$,

light yellow needles (no dioxime could be obtained); *benzoate*, m. 154° . With HNO_3 (d. 1.1) on the H_2O bath the oxime gives *dichloronitro-m-cresol*, light yellow needles from ligroin, m. 128° , decomp. a little higher. $\text{SnCl}_2\text{-HCl}$ reduces the oxime to the quinol. 3-Chlorotoluquinone and HCl yield, besides about 5% of tri- Cl compd., 3,6-dichlorotoluquinone, sepg. from alc. on standing after addition of H_2O in golden yellow prisms with alc. of crystn., m. 67° ; a hot satd. alc. soln. of the prisms deposits alc.-free leaves, stable in the air, m. 76° ; on long standing in the mother liquors they go over into the alcoholated prisms. With SO_2 in alc. is obtained the *quinol*, needles, m. 85° ; *diacetate*, prisms or fine needles from alc., m. 110.5° . 3,6-Dichlorotoluquinone *oxime*, light yellow needles, m. 135° , then immediately decomp., sol. in dil. alkalies with greenish yellow color; *acetate*, rhombic prisms from C_6H_6 , m. 85° , $a:b:c = 0.86265:1:1.1592$, showing light yellow-brown pleochroism. *Dichloroaminocresol*, from the oxime and $\text{SnCl}_2\text{-HCl}$, thick needles from C_6H_6 , m. 128° ; *diacetyl derivative*, needles, m. 129° . *Dichloronitrocresol*, from the oxime and HNO_3 (d. 1.1) at room temp., light yellow crystals from ligroin, m. 135° ; *acetate*, yellowish white needles from ligroin and C_6H_6 , m. 98° .

CHAS. A. ROULLIER.

Esters of tertiary trichlorobutyl alcohol and their pharmacology. R. WOLFFENSTEIN, A. LOEWY AND M. BACHSTEZ. Charlottenburg and Berlin. *Ber.* 48, 2035-43 (1915).—In order to test the pharmacological influence of esterification on alcs., various esters of the pharmacologically active $\text{CCl}_3\text{CMe}_2\text{OH}$ (a) were prepd. Indications were obtained that by treating (a) with finely divided Na in PhMe its Na alcoholate is formed but a repetition of the expt. led to a violent explosion. No reaction between (a) and PCl_5 could be observed (cf. Willgerodt and Dürr, *Ber.* 20, 539(1887)). (a) forms a well-defined hydrate. Anhydrous (a) in Et_2O stratified with decolorized fuchsin- SO_2 soln. gives a violet color. The esters were prepd. from the corresponding acid chlorides with or without the aid of tertiary bases, or from the acids in the presence of a condensing agent. *Propionate* (b), yellowish oil, b_{14} 88-90°. *Isovalerate* (c), b_{20} 108-10°. *Bromoisovalerate* (d), b_{17} 152°. *Chloroacetate* (e), crystals from dil. alc., m. 48°. *Trichloroacetate* (f), needles from dil. alc., m. 40°. *Diethylglycinate* (g), from (e) and NHEt_3 , b_{20} 142-5°; *hydrochloride*; solns. of salts with org. acids (AcOH) dissociate on warming, the free (g) sepg. but redissolving on cooling; *chloroplatinate*, platelets, m. 212°. *Dimethylglycinate* (h), from 20 g. (e) shaken 5 hrs. at 100-10° with 30 cc. of 27% aq. NHMe_3 , oil; *hydrochloride*, rhombic platelets, m. 220°. *Piperidylacetate* (i), oil slowly crystg. on standing, has an AcNH_2 -like odor and an intensely bitter taste. *Allophanate* (j), from NH_2COCl and (a) at room temp., crystals from dil. alc., m. 114°. *Acid malonate* (k), from 35 g. (a) and 22 g. $\text{CH}_3(\text{CO}_2\text{H})_2$ heated several hrs. with 3 g. ZnCl_2 , 6-sided platelets from 50% alc., m. 116°. *Neutral malonate* (l), m. 102-3°, insol. in alkalis. *Dibromocinnamate* (m), m. 99-100°. These esters are not hydrolyzed in the organism, each exerting an action peculiar to itself, often entirely different from that of its components and of an unexpected nature. The toxicity of homologous esters increases with the mol. wt. As compared with (a) its acetate shows decreased narcotic and increased toxic action; this is true to an increasing degree of (b) and (c); (c) is no longer narcotic but is a convulsant poison (to rabbits); this also holds for (d) and the diethylaminovalerate. (e) and (f) are less powerful, both as narcotics and poisons, than the acetate. The pyruvate and (j) are strongly toxic but not at all narcotic. (g) and (h) have pronounced narcotic action while (i) is a convulsant but not a narcotic. (k), (l) and substituted malonates are wholly non-toxic and not at all pronouncedly narcotic; the cinnamate and (m) are not narcotic. Further evidence that these esters are not hydrolyzed in the organism was obtained by prepg. esters of acids which give characteristic color reactions and are known to pass through the organism unchanged; none of these color reactions was given by the products of excretion of the animals treated with such esters. The full pharmacological report is published simultaneously in *Arch. exp. Path. Pharm.* C. A. ROUILLER.

The Friedel-Crafts ketone synthesis in the pyridine series. RICHARD WOLFFENSTEIN AND FRANK HARTWICH. Charlottenburg. *Ber.* 48, 2043-9(1915).— $\text{C}_5\text{H}_5\text{N}$ and its salts, treated under the most varied conditions with AcCl or BzCl in the presence of AlCl_3 , never yielded the ketone sought; in some cases there was an energetic evolution of HCl but only tarry products resulted. The same is true of quinoline and isoquinoline, even when negative substituents are introduced into the ring (2,3,4-trichloro-, 8-hydroxy- and 5,7-dichloro-8-hydroxyquinoline). Even Halla's method, starting from pyridinecarboxyl chlorides and aromatic hydrocarbons (*C. A.* 5, 3688), failed when pure materials were used, and success was attained only when the SOCl_2 used in the prepn. of the acid chlorides was not quant. removed. With di- COCl compds., the reaction takes place easily even when the SOCl_2 is carefully removed. α -Pyridinecarboxyl chlorides differ from the others in forming with $\text{C}_6\text{H}_5\text{N}$ characteristic dyes with beautiful blue shades, a reaction also dependent on the presence of SOCl_2 . The tendency to form these dyes is so great that in prepg. α - $\text{C}_6\text{H}_5\text{NCOCl}$

if it is attempted to remove the excess of SOCl_2 at a rather high temp. on the H_2O bath *in vacuo* apparently a small amt. of unchanged $\text{C}_6\text{H}_5\text{NCO}_2\text{H}$ loses CO_2 and the resulting $\text{C}_6\text{H}_5\text{N}$ combines at once with the chloride to give the dye. The intensely corn flower-blue dye is extraordinarily sensitive to light and air. The prepn. of α, α' - and α, β' - $\text{C}_6\text{H}_5\text{N}(\text{CO}_2\text{H})_2$ is rendered much easier by taking advantage of their slight soly. in H_2O , so that it is not necessary to purify the com. $\text{C}_6\text{H}_5\text{NMe}_2$ from which they are made by oxidation or to purify the acids through the Ag salts. The various chlorides, prepd. from the acids and SOCl_2 , are freed from most of the SOCl_2 *in vacuo* at room temp., warmed with several parts of the aromatic hydrocarbon (with some CS_2 if necessary) to incipient boiling and then treated with somewhat more than the calcd. amt. of AlCl_3 in small portions (with the di- COCl compds. it is best to prep. the AlCl_3 double compd. first by gently warming the components and then to add the hydrocarbon); the heating is continued as long as HCl is evolved, the excess of hydrocarbon distd. off, the residue decompd. with ice H_2O , the rest of the hydrocarbon removed with steam, the residue cooled, made alk. and extd. with Et_2O . In this way were obtained the following ketones: α -Pyridyl phenyl ketone, almost colorless oil, b_{14} 182° ; chloroplatinate, m. 193° (decompn.). Anisyl ketone, silky needles from alc., m. 93° ; chloroplatinate, m. 210° (decompn.); picrate, m. 176° ; phenylhydrazone, brownish druses, m. 103° . β -Pyridyl phenyl ketone, light yellow oil, b_{12} 180° , solidifies after months to crystals, m. 39° ; chloroplatinate, m. 267° (decompn.). Anisyl ketone, needles from alc., m. 99° ; chloroplatinate, m. 267° (decompn.); picrate, m. 185° ; phenylhydrazone, light yellow needles, m. 157° . Naphthyl ketone, brown resin; chloroplatinate, m. 213° (decompn.); picrate, m. 142° . α, β' -Dibenzoylpyridine, pointed crystals from alc. m. 123° ; chloroplatinate, from 25% HCl , decomp. into its components on treatment with cold HCl or on exposure to the air; diphenylhydrazone, m. 129° (not sharply). α, α' -Dibenzoylpyridine, needles from alc., m. 108° , so weakly basic that it forms no double salts; diphenylhydrazone, m. 183° .

CHAS. A. ROUILLER.

Preparation of aromatic tellurium compounds. KARL LEDERER. Brussels. Ber. 48, 2049-54(1915); cf. C. A. 9, 3235; Rohrbach, Ann. 315, 9(1901).—By the action of $p\text{-MeOC}_6\text{H}_4\text{MgBr}$ on TeBr_2 , L. has obtained a compd. entirely different from that prepd. by R. by heating in sealed tubes the compd. formed by treating TeCl_4 with PhOMe , and L. feels certain that R.'s compds. are not p -substituted derivs. When to the Grignard reagent from 143 g. $p\text{-BrC}_6\text{H}_4\text{Me}$ and 20.7 g. Mg in 500 cc. Et_2O is slowly added 60 g. TeBr_2 , the mixt. boiled 3 hrs., decompd. with ice H_2O , digested thoroughly with Et_2O , the ext. repeatedly washed with H_2O and distd., there are obtained, besides PhMe and a little $\text{BrC}_6\text{H}_4\text{Me}$, 4.7 g. $(p\text{-MeC}_6\text{H}_4)_2$ and $(p\text{-MeC}_6\text{H}_4)_2\text{Te}$ (a), converted in Et_2O into the dibromide (b) (54 g.); in the distg. flask remains the $(\text{MeC}_6\text{H}_4\text{Te})_2$, sepg. from Et_2O and alc. only in tarry form. From 108 g. $\text{BrC}_6\text{H}_4\text{Me}$, 15.9 g. Mg and 60 g. TeI_2 in the same way are obtained 3.1 g. $(\text{MeC}_6\text{H}_4)_2$ and 41 g. (b). From 100 g. (b) in about 15 l. hot H_2O treated with Na_2SO_3 , cooled, extd. with Et_2O and distd. over Cu powder is regenerated (a), b_{18} $211\text{--}2^\circ$, m. $69\text{--}70^\circ$. The o-compd., b_{18} $202\text{--}3^\circ$, m. $37\text{--}8^\circ$, is similarly obtained; yield of dibromide, 59 g. from 143 g. o- $\text{BrC}_6\text{H}_4\text{Me}$, 20.7 g. Mg and 60 g. TeBr_2 , and 51 g. from 108 g. $\text{BrC}_6\text{H}_4\text{Me}$, 15.9 g. Mg and 60 g. TeI_2 . When 25 g. TeCl_4 and 25 cc. PhOMe are rubbed together on a boiling H_2O bath and, after the reaction has ended (about 15 min.), are dissolved in 150 cc. of 10% NaOH , freed from excess of PhOMe with Et_2O , treated with 36 g. $\text{Na}_2\text{S}_2\text{O}_4$ in 150 cc. H_2O and 25 cc. of 10% NaOH , made distinctly alk. after the reduction has ended, the resulting telluride taken up in C_6H_6 , dried with CaCl_2 , boiled with Cu powder and evapd., there is obtained 21 g. of dianisole telluride (c) (L. gives $(\text{MeOC}_6\text{H}_3\text{-H})_2\text{Te}$ for its formula—ABSTR.), sepg. from 800-900 cc. petr. ether in dark red needles with metallic luster, m. 50° . In the same way from 25 g. TeCl_4 and 25 cc. PhOEt is ob-

tained 23 g. *diphenetole telluride*, orange-red leaflets from 650 cc. alc., m. 64°. From 2 g. (c) gently boiled 0.5 hr. with 1 cc. MeI is obtained a red-brown mass sol. in hot H₂O; addition of aq. picric acid to the hot soln. ppts. a red-brown product and then broad, yellow needles sepg. from alc. in yellow crystals, m. 126-7°, having the compn. (MeOC₆H₅-H)Me₂Te.C₆H₅O₇N₄. CHAS. A. ROUVILLER.

Degradation of scopoline. Scopoline → hyoscopoline → scopolinic acid. KURT HESS AND A. SUCHIER. Univ. Freiburg i/B. *Ber.* 48, 2057-67(1915).—From the evidence thus far available, scopoline (a) may be represented by the formula C₇H₉(NMe)(OH)(O<). Attempts to throw light on the structure of the residue C₇H₉ by oxidative degradation of (d) itself with CrO₃ failed. In the hope of converting norscopoline (b) into an amino ketone it was treated with HCHO (C. A. 10, 467). but (a) was quant. regenerated, and H. and S. conclude that in (b) and probably in (a) also the C atom to which the OH group is attached carries no oxidizable H atom, i. e., that the HO group is probably tertiary. Willstätter and Hug's chloroscopoline (C. A. 7, 78) also did not prove suitable for degradation expts., as the Cl atom is very resistant. When, however, 10 g. (a) is heated 4 hrs. at 115-20° with 50 g. HBr-AcOH (satd. at 0°), concd. to a syrup in CO₂ at 40-50° under 16 mm. and to a glassy, faintly yellow mass (12.6 g.) under 0.06 mm., dissolved in a little concd. HCl, again evapd. *in vacuo* over soda-lime and crystd. from just the necessary amt. of hot MeOH (about 150 cc.) there is obtained 8.7-9.5 g. of *hyoscopoline bromide hydrobromide* (c), C₈H₁₆O₂NBr₂, quadrangular prisms, m. 210-1° (decompn.), easily decompd. by boiling H₂O, exceedingly sensitive towards alkalis, especially on warming, the soln. quickly turning yellow, then red and finally brown. The mother liquors from (c), evapd. to dryness *in vacuo*, taken up in hot EtOH and cooled in ice-NaCl, yield *diacetylhyoscopoline bromide hydrobromide*, elongated crystals consisting of microscopic triclinic pyramids, changes color 250°, sinters 270-80°, m. 283-5° (gas evolution). From 9.2 g. (c) in 230 cc. of 20% H₂SO₄ slowly treated with 12 g. Zn dust at such a rate that the temp. remains at 29-30°, then warmed 1 hr. on the H₂O bath, filtered, neutralized with soda, evapd. to dryness at 40-3° under 18 mm. and extd. with alc. in a Soxhlet, is obtained 9.5 g. of the *zinc bromide double salt*, 2 C₈H₁₆O₂NBr.ZnBr₂, long spears from hot AcOH, m. 215-6°; 8.5 of this in 50 cc. H₂O made just alk. with 20% soda, filtered from the ZnCO₃, concd. to a few cc. at 40° under 18 mm., supersatd. with concd. NaOH and extd. with CHCl₃, yields 3.6 g. of *hyoscopoline* (d), C₈H₁₆O₂N, m. 165°, strongly alk. to litmus, reduces NH₄-AgNO₃, quickly decolorizes cold Br-H₂O, crysts. best from Me₂CO-MeOH. *Hydrobromide*, m. 260° (decompn.). *Picrate*, needles from alc., m. 232°. *Chloroaurate*, m. 200°. From 3 g. of (d) in 15 cc. H₂O cautiously warmed on the H₂O bath with 7.5 g. CrO₃ in 12 g. concd. H₂SO₄ and 150 cc. H₂O until there is a color change, then heated 2 hrs. at 85-90° and finally boiled 45 min., freed from excess of CrO₃ with SO₂ and from Cr with NH₄OH, evapd. to dryness *in vacuo*, boiled with dil. NaOH to remove the NH₃, acidified with HCl, evapd., extd. with alc. and concd., there is obtained *scopolinic acid hydrochloride*, C₈H₁₆O₂NCl, polygonal tables with 1 H₂O, m. 225-6° (decompn.), which with Ag₂CO₃ gives the free *acid*, identical with α,α'-N-methylhexahydrolutidinic acid (C. A. 10, 471). (a) is, therefore, an alkaloid of the piperidine series and the 2 extra C atoms are in the α-positions to the N atom, so that (a) may be represented by the formula

CHAS. A. ROUVILLER.

FRANK P. UNDERHILL.

Action of honey on the teeth. H. P. PICKERILL. *New Zealand Dental J.*; through *Chemist Druggist* 88, 55(1916).—Honey taken by itself has a bad effect on the teeth, but this is counteracted by adding 1% tartaric acid. Tables are given of the acid formed in the mouth 5 min. after eating various foods. C. O. EWING.

Permeability. I. Exosmosis of electrolytes as a criterion of antagonistic ion action. W. STILES AND I. JORHENSEN. *Ann. Botany* 29, 349-67(1915).—A study of the relations existing between plant tissue and a soln. surrounding it, by examn. of the changes in elec. cond. of the latter. The tissues used consisted of disks of potato tuber, having a diam. of 1 cm. and a wt. of 0.5 g. Twenty such disks were washed in distd. water, dried on filter paper, placed in 100 cc. of soln. in a stoppered bottle, and the cond. of the soln. was measured from time to time by Kohlrausch's method. In some cases living plants of bean were used. It is probable that within certain limits the rate of exosmosis is a measure of toxicity. A decrease in this rate when certain ions are added to solns. containing poisonous ions might be due to "antagonism."

B. HOROWITZ.

Serological studies of Leguminosae and Gramineae. A. ZADE. *Habil.-Schrift*, Jena 1914, 51 pp.; *Zentr. Biochem. Biophys.* 18, 285(1915).—Z. concludes that expectations for the practical utilization of the biological method of differentiation can only be provisionally accepted at the present time, although there is no reason to suppose that further elaboration of the method may not lead to results which are of practical value.

H. S. PAINE.

The activity of other enzymes which accompany β -glucosidase in emulsin in the synthesis of alcohol- β -glucosides. EMILÉ BOURQUELOT AND A. AUBRY. *Compt. rend.* 161, 463-6(1915).—Emulsion of almonds contains β -glucosidase, lactase, β -galactosidase, gentiobiase and cellobiase. β -Glucosidase synthesizes alcohol- β -glucoside from alcohol and β -glucose. Lactase and galactose are without effect in this synthesis. The hexobiases, i. e., gentiobiase and cellobiase exercise an inhibiting action on the alcohol-glucoside synthesis, by converting the glucose into disaccharides. The activity of the hexobiases is directly proportional to the concn. of glucose and inversely proportional to the amt. of H_2O used. The concn. of alcohol is immaterial in this reaction.

W. A. PERLZWEIG.

The mechanism of antagonistic salt action. JACQUES LOEB. *Proc. Nat. Acad. Sci.* 1, 473-7(1915).—A brief review of the theory. W. A. P.

Maltase. ALBERT ÖHMAN. *Upsala. Läkareförenings Förhandlingar* 20, 145-68 (1915).—Maltase prepared from yeast gradually loses its power to hydrolyze maltose upon dialysis. If to the dialyzed prepn. is added some of the maltase which has been boiled, the maltase dialyzed is activated provided that the dialysis has not proceeded so far that all of the enzymic activity has been removed. The activity of this maltase after dialysis is also increased by adding phosphate. $NaCl$, $NaNO_3$, $(NH_4)_2SO_4$, $CaCl_2$ and $MgSO_4$ do not increase the activity of the maltase. The action of the phosphate on the maltase is not the same as its action on zymase. The phosphate does not increase the cleavage of the maltose by virtue of keeping yeast proteins in soln. The cleavage is increased by diln. and inhibited by the increase of dextrose, fructose, mannose, and galactose in the reaction mixt. The presence of $CHCl_3$ does not hinder the hydrolysis. There is a German summary to the article. A. R. ROSE.

Carboxylase (BAU) 16.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

Estimation of sugar in urine with "nitro-propiol" tablets, and some other tests. F. WOLTER. *Pharm. Ztg.* 60, 634-5(1915).—W. finds that all urines yield with this reagent a more or less distinct blue color, *i. e.*, positive reaction; hence he pronounces it untrustworthy. Instead, Heine's soln. is recommended as being more dependable, the reagent and urine being boiled separately, whereupon the latter is added to the former drop by drop. The nitric acid test for albumin is likewise condemned on account of its failure to indicate small quantities of albumin. A better method consists in the addition to the sample of about 11 drops dil. AcOH and $\frac{1}{2}$ satd. NaCl soln. followed by boiling the mixt., traces of albumin being indicated through the formation of a distinct turbidity. In the blood benzidine test, better results are obtained by proceeding as follows: Dissolve the benzidine in concd. AcOH and shake with H_2O_2 , then cover with the urine. In the presence of blood a beautiful deep green ring appears at the surface of contact of the 2 liquids. In examg. the feces for blood, a satisfactory test is obtainable only after the patient has been denied meat for 3 days. W. O. E.

Method for the determination of arsenic in urine, blood and parts of cadavers. WILHELM KOSIAN. *Pharm. Post* 48, 321(1915).—Marsh's method involves preliminary ashing of the organic material, and the prepn. of a proper normal mirror for comparison, which is difficult for the inexperienced. The titrimetric method of Györy (*Z. anal. Chem.* 32, 415-21(1893)) can be used to det. As in org. or inorg. combination. Method: evap. 100-150 g. urine, blood, or serum to a sirupy consistency (parts of cadavers or stomach contents are ground up), place in 600 cc. flask, add 20 cc. fuming HCl and a small amt. $KClO_3$, and warm gently. Heat to expel Cl, add 10-15 g. $FeSO_4$ and dil. to 200 cc. with As-free HCl. Sat. with HCl gas, distil 80-100 cc. in a current of HCl into a cooled flask containing 50-100 cc. H_2O . Make up to 200 cc. and titrate 10 cc., to which 3 cc. concd. HCl has been added, with 0.1 or 0.01 N $KBrO_3$ soln., using Me orange indicator. (The indicator is decolorized at the end-point.) It is possible to det. 0.44 mg. As in 1 cc. per cc. blood or urine.

C. O. EWING.

The osazone method of locating sugars in plant tissues. SYDNEY MANGHAM. *Ann. Botany* 29, 369-391(1915).—The reagent employed is that introduced by Senft (*Süssb. Akad. Wiss., Wien, mathem.-naturw. Klasse* 113, Abt. I, p. 3). The phenylhydrazine hydrochloride is rubbed up with pure glycerol in a mortar, warmed and well shaken in a bottle kept stoppered to prevent undue access of air. When the soln. is fairly complete the reagent is warmed and filtered at least once. Sections of plant tissues are laid in a mixture of this reagent and a glycerol soln. of Na acetate, and heated at 98-100° for about 1 hr. Levulose readily yields an osazone, dextrose somewhat less readily. Cane sugar, if present in sufficient concn., may become partly hydrolyzed. Maltose, after being heated for 1 hr., forms a golden yellow sirup from which crystals may slowly form.

B. HOROWITZ.

Practical application of refractometry of blood serum. EMIL REISS. Frankfurt a/M. *Deut. Arch. klin. Med.* 117, 175-9(1915); *Zentr. Biochem. Biophys.* 18, 273(1915).—R. discusses critically the presumptions which are involved in a comprehensive application of refractometry to blood serum.

H. S. PAINE.

Differential stain for urine sediment. E. W. FITTIPALDI. *Gazz. ospedali clin.* 36, No. 81(1915); *J. Am. Med. Assoc.* 66, 231.—A triacid stain is used containing aniline blue w, aurantia and eosin. The aniline blue w soln. is made with 1 part stain to 100 parts of 10% alc.; aurantia with 0.2 part stain to 100 parts 10% alc.; eosin is used in a 1% soln. The triple stain is then prepd. by mixing the above solns. in the proportion of 45, 35, and 20 parts, respectively. By means of a glass rod a small amt.

of the stain is placed on the specimen to be examd. and a small drop of physiologic salt soln. containing 2% AcOH is stirred in; this decolorizes the vehicle while fixing the stain on the morphologic elements. The specimen is then slightly heated.

L. W. RIGGS.

Claudius' quantitative colorimeter test for albumin. A. NORGAARD. *Ugeskrift Laeger* 77, No. 47(1915); *J. Am. Med. Assoc.* 66, 318.—A thorough trial of this method, with 100 specimens of urine and other organic fluids, shows that with an albumin content below 1 per 1000 there may be a difference up to 10% as compared with gravimetric methods. With the albumin content above 1 per 1000 the difference may rise to 20 or 30%. For the exact technic of this method cf. *Hospitalstidende*, 58, No. 48(1915).

L. W. RIGGS.

New process of coloration of spermatozoa on suspected spots. SEMENOVSKI. Jurjev, Dorpat. *Pharmazetisches J.* 1915, 142; *J. pharm. chim.* 12, 297-8(1915).—Cut the suspected fabric into pieces 3 to 5 mm. long, dip them into a freshly prepared bath of iodococin 0.1, KOH 5.0, H₂O 100.0; for 10 or 15 seconds, then into 96% EtOH for 10 seconds. Dry between filter paper, shred the fibers with a needle, and exam. under the microscope. The spermatozoa are clearly stained an intense red upon the uncolored background of the fibers. Spots even 10 yrs. old show the test well, and the prepn. may be mounted in Canada balsam and kept indefinitely. Bengal red, erythrosin and even eosin may replace iodococin.

S. WALDBOTT.

A biological test for arsenic. ALBERT SCHNEIDER. *J. Am. Pharm. Assoc.* 4, 1307-9(1915).—A review of the work done by Gosio who showed that certain molds grown in and upon media containing very minute quantities of arsenic gave rise to gaseous compounds characterized by a garlic-like odor.

M. I. W.

Routine chemical laboratory tests; their description and significance. FRED L. LACKENBACH. *J. Am. Pharm. Assoc.* 5, 17-20(1915).—A review of biological, microscopical and chemical tests used for diagnostic purposes.

M. I. W.

The preparation of serums and antitoxins. CHARLES M. TWINING. *J. Am. Pharm. Assoc.* 5, 21-9(1915).—A review of the problems involved in the manufacture of sera, including a discussion of the difficulties encountered in the selection of animals.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The fermentative power of marine bacteria. H. COUPIN. *Compt. rend.* 161, 597-600(1915).—C. has studied qualitatively the fermentative action of 43 new species of marine bacteria upon some carbohydrates. Only 4 species were totally inactive.

W. A. PERLZWEIG.

Reaction of the medium and filtration of toxins. E. AUBEL AND H. COLIN. *Compt. rend.* 161, 506-8(1915).—Filtrates from alkaline cultures of diphtheria and dysentery bacilli were toxic; filtrates from acid cultures were not toxic. Dil. alkaline exts. of cultures when filtered were shown to be more active than neutral or acid exts.

W. A. PERLZWEIG.

D. BOTANY.

CARL L. ALSBERG.

Localization of acids and sugars in fleshy fruits. E. DEMOUSSY. *Compt. rend.* 161, 443-5(1915).—The physical structure of cells in fleshy fruits detrs. to a great extent their chem. compn. Acids and reducing sugars are expressed to the greatest extent with high crushing pressure on the fruits, whereas non-reducing sugars are obtained with slight pressure. No definite conclusions are reached as to the localization of acids and sugars in fruits.

W. A. PERLZWEIG.

Formation of anthocyan pigments in plants. A. GUILLIERMOND. *Compt. rend.* 161, 494-7, 567-70(1915).—A survey of the histological origin of anthocyan pigments. W. A. PERLZWEIG.

The displacement by water of the nitrogenous and mineral material in leaves (ANDRÉ) 15.

E. NUTRITION.

PHILIP B. HAWK.

NORMAL.

Nutritive value of corn from recent and older harvests. J. J. NITZESCO. Bucharest. *Compt. rend. soc. biol.* 77, 583-6(1915); *Bull. acad. Roumain.* 4, 42-54.—N. studied the nutritive value of corn of different ages with particular reference to the occurrence of pellagra in cases of practically exclusive maize diet. Rats, hens and cocks received a diet of new corn as well as corn which was 1-3 yrs. old. Total N, starch and uric acid were detd. in the excreta of the fowls; total N and urea were detd. in the urine of the rats, while total N and starch were detd. in the feces. New corn was found to be less digestible and assimilable than old corn. An exclusive corn diet of long duration was tolerated with greater difficulty by the rats than by the fowls.

H. S. PAINE.

F. PHYSIOLOGY.

ANDREW HUNTER.

Contribution to the chemistry of nervous tissue. II. Determinations of phosphorus in the ventral and dorsal medullary cord of the ox. G. BUGLIA AND D. MAESTRINI. Univ. Pisa. *Arch. farm. sper.* 18, 221-32(1915); cf. C. A. 8, 2181; 9, 478.—The total P contained in the dorsal is greater than that contained in the ventral medullary cord. It consists principally of organic P, phosphatide P in particular.

A. W. DOX.

Adaptation to low temperatures and death by chilling. A. MONTUORI AND R. POLLITZER. Univ. Rome. *Arch. farm. sper.* 20, 392-405(1915).—Defibrinated blood from an animal which had been slowly chilled, injected intraperitoneally into another animal of the same species, renders the latter more resistant to cold (8°) and prevents or retards a lowering of the body temp. On the other hand, if the first animal has been suddenly and intensely chilled so that there is no longer a corneal reflex, the injection of defibrinated blood diminishes the normal resistances of the second animal to low temps., and rapidly causes hypothermia.

A. W. DOX.

The function of the hypophysis. I. Influence of the hypophysis on the metabolism of carbohydrates. ORESTE MASI. Univ. Pisa. *Arch. farm. sper.* 20, 450-66(1915).—Injection of aq. ext., glycerol infusion or commercial prepn. of hypophysis causes a slight glucosuria. When adrenaline and hypophysis prepn. are administered simultaneously the glucosuria is more intense than that produced by adrenaline alone.

A. W. DOX.

Does the pituitary gland contain epinephrine or a compound similar to it? WALTER K. WATANABE AND ALBERT C. CRAWFORD. San Francisco. *J. Pharmacol.* 8, 75-88(1916).—Previous contributions on the subject seemed to suggest that epinephrine, or a compd. similar to epinephrine, was responsible for much of the pressor action of the pituitary gland, and that this might be modified by the presence of other compds. along with colloids, etc. For isolating epinephrine from the pituitary gland a modified form of Weidlein's method (C. A. 7, 1403) was used. Proof of the presence of epinephrine was sought by means of color reactions and physiological tests. It was found that pituitary exts. prepd. by certain methods give color reactions similar to those given by suprarenal exts.; slowing of heart rate (dog) was noted from a prepn. in which no pressor action was detected; pituitary exts. cause strong contraction of non-

pregnant cat uterus, and if a certain amt. of epinephrine is added to the pituitary ext., the characteristic action of pituitary ext. on cat uterus is not changed; after ergotoxin injection, pituitary ext. causes a lowering of blood pressure as by epinephrine; isolated intestine (cat and rabbit) was strongly contracted by pituitary ext. and relaxation was not obtained by the addition of a certain quantity of epinephrine to such exts.; by oxidation with MnO_2 pituitary exts. lose their pressor action and some of their color reactions, but retain in part their action for both non-pregnant cat uterus and rabbit and cat intestine. Physiologically the presence of epinephrine or an epinephrine-like compound in pituitary exts. is suggested, and certain color reactions indicate this also, but epinephrine has not as yet been isolated from the gland; this may be due to the small amt. present or inadequacy of the method.

P. J. HANZLIK.

Extraphysiological or putrefactive urea. G. DELGADO PALACIOS. *Am. J. Med. Sci.* 149, 267-77 (1915).—P. believes that in the common conditions in normal human subjects, a minimum of 300 mg. of NH_3 is produced every 24 hrs. in the large intestine as a result of putrefactive processes, and that this NH_3 , after having been absorbed into the blood, appears in the urine as a minimum of 0.5 g. and even 1 g. of putrefactive urea. To this daily amt. of putrefactive urea corresponds normally the production of several milligrams of acetone.

TULA LAKE HARKEY.

The lipoids contained in the ovary. C. SERONO AND A. PALOZZI. *Rass. clin. terap. sci. affini* 14, 293 (1915).—A chem. study of cow ovaries. Fresh glands were ground up and extd. with Et_2O , $EtOH$ and $CHCl_3$. The exts. were evapd. and the various lipoids sepd. according to their solubilities in acetone, Et_2O and $CHCl_3$. The lipoids were found to be similar to those of egg yolk. Their wt. varied from 3.05 to 4.89% of the total wt. of the ovary, the adult ovary being richer in lipoids on account of the corpora lutea which it contains. Chem. analysis of the lipoids showed the following av. compn.: cholesterol (free and combined) 3.68, lecithin 19.72, cerebrin and homocerebrin 4.47, fatty acids (oleic, palmitic, stearic, myristic) and glycerol 72.13, total 100%.

D. I. MACHT.

Lipoids of the corpus luteum. C. SERONO AND A. PALOZZI. *Rass. clin. terap. sci. affini* 14, 299 (1915).—Fresh corpora lutea of the cow were treated as described in the preceding abstract; they yielded 6.39% of lipoids (m. p. 44-45°). Dried corpora lutea yielded 18.59% lipoids. Analysis of the lipoids showed them to contain: cholesterol 13.62, fatty acids and cerebrosides 54.81, lecithin 28.58, loss 2.99, total 100.00%. Corpora lutea have no physiological function or internal secretion, except through decompn. products. Gall-stones, so common in women, may have a relation to the large amts. of free cholesterol eliminated monthly by the corpora lutea undergoing absorption. The authors regard lutein as an oxidation product and of no importance. Lutein is a chromogen common as an oxidation product of all lipoids. Ovary and ovum have therefore a very analogous lipid content, and a specific function is not attributable to them, but is to be sought rather in the internal activity of the ovary itself, which is rich in enzymes.

D. I. MACHT.

Phagocytes and respiration centers. Their behavior when acted on by oxygen, carbonic acid and fat-dissolving substances. Explanation of the excitement stage in narcosis. H. J. HAMBURGER. Groningen. *Proc. Akad. Wetenschappen* 17, 1325-52 (1915); *Verslag. Akad. Wetenschappen* 23, 1190-1206.—Expts. showed that phagocytosis was increased by decreasing the O supply, e. g., by exposing to an atm. almost O-free; complete removal of O results in a retardation of phagocytosis. KCN in great diln. also increases phagocytosis, as does the presence of a trace of CO_2 . The analogy between phagocytes and respiration centers is pointed out, and the observations, taken in connection with the fact that narcotics impede the O consumption of

cells such as the spinal centers, etc., affords an explanation of the excitement stage in narcosis.

GEORGE W. MORRY.

Function of the kidneys with reference to amino acids. R. LANZILLOTTA. Naples. *Arch. fisiol.* 12, 429-40; *Zentr. Biochem. Biophys.* 18, 117-8(1915).—L. studied the mechanism by means of which the concn. of amino acids in the blood is regulated, as well as the participation of the kidneys in this function. Proceeding on the theory that the concn. of amino acids in the urine depends on their concn. in the blood, L. performed a series of artificial perfusions in isolated dog kidneys; solns. of alanine, glycocoll, tyrosine, and aspartic acid were employed, and in each case the amino N in unit vol. of circulating liquid and product of renal secretion was detd. Perfusion with aspartic acid gave results somewhat different from those obtained in the other expts.; the total amino N (*i. e.*, that present in various portions of the circulating liquid and in the product of secretion) was found to be greater than the amino N introduced at the beginning of the expt. This result is probably due to the acid character of aspartic acid and its hydrolyzing action on kidney albumin. In the case of alanine, glycocoll and tyrosine the Van Slyke app. showed 0.8-19% less amino N than was originally dissolved in the Ringer soln. There was no appreciable difference between the amino N concn. in the perfusion liquid and kidney secretion. It is, therefore, probable that there is no selective secretion process on the part of the kidneys toward amino acids, but rather a simple filtration by the renal glomeruli. There exists, however, a destructive action of the kidney toward amino acids, the degree of which may be more or less pronounced for various amino acids and, in the case of different kidneys, for one and the same amino acid.

H. S. PAINE.

Physiological value of the suprarenal gland in depancreatized animals. E. GLEY. *Compt. rend. soc. biol.* 78, 1-3(1915).—The suprarenals of depancreatized diabetic dogs, as well as dogs which had received an injection of gelatin or tallow in the duct of Wirsung, were dried *in vacuo* and the vasoconstrictor action of the ext. was tested on dogs and rabbits; the values of arterial pressure produced by these exts. did not differ materially from those due to exts. of normal glands. These results fail, therefore, to substantiate the theory of a regulatory action of the pancreas on suprarenal function and intensification of the latter in cases of pancreatectomy.

H. S. P.

New experiments on the theory of the muscle machine. VIKTOR WEIZSÄCKER. Heidelberg and Cambridge. *Münch. med. Woch.* 62, 217-57(1915); *Zentr. Biochem. Biophys.* 18, 121-2(1915).—W. describes the results of study by exptl. pharmacol. methods (also myothermic expts. in salt solns.) of the phenomena of oxidation, heat production and performance of work in the muscle machine, the latter being regarded as a distinct and isolated system. The heat produced during contraction (the so-called "initial heat") remains the same regardless of whether oxidation occurs or not. Less heat is produced in the contraction of muscle (for contractions of the same extent) as the heat of the latter increases; this is an indication of the economic working of the muscle. The initial heat decreases by about 40% for each 10° increase in temp. Heat production and performance of work are quite independent of each other and are to be regarded as distinct functions. It may, therefore, be assumed that a non-oxidative process provides the energy for initial heat and work. The total activity of the muscle machine may be considered as due to a work-performing and a restitutive machine which act in a circle, so to speak; the former transforms potential energy into work and heat and the latter replenishes this energy through the action of oxidation.

H. S. PAINE.

Blood coagulation in infancy. H. L. K. SHAW AND F. J. WILLIAMS. Albany. *Albany Med. Ann.* 34, No. 12(1915); *J. Am. Med. Assoc.* 66, 219.—Blood from 108 healthy infants, under 2 years of age, was examd. by the Dale and Laidlaw method (cf.

C. A. 6, 1016) and found to coagulate in from 75 to 108 sec., the av. period being 90 sec., which is slightly shorter than that for adults. No difference was observed in the clotting time before and after eating, at different periods of the day, or in blood from different parts of the body. In a later paper the authors expect to compare these results with those obtained in various diseased conditions. L. W. RIGGS.

Galactose test of liver functioning. G. A. PARI. *Gazz. ospedali clin.* 36, No. 78(1915); *J. Am. Med. Assoc.* 66, 70.—P.'s work has confirmed the fluctuations in the response to the galactose test in the same person at different times, showing that a single test has but little significance. In the cases observed its functioning varied inversely with the amts. of ascitic fluid produced. L. W. RIGGS.

Liver formation of urea from amino acids. B. C. P. JANSEN. *Nederlandsch. Tijdschrift Geneeskunde* Nov. 20, 1915; *J. Am. Med. Assoc.* 66, 317.—J.'s expts. with cats and dogs and on the surviving liver after its vessels had been flushed clean with warm Ringer soln., show that the liver may play an important part in the formation of urea from amino acids. In the different tests from 0.3 to 0.5 g. of urea was found, corresponding to a production of from 7 to 8 g. per day. These findings do not agree with the results obtained by Folin under similar conditions, nor with those of Fiske and Karsner. L. W. RIGGS.

Suprarenal capsules and lactation. C. VERDOZZI. *Policlinico* 22, No. 11(1915); *J. Am. Med. Assoc.* 66, 155.—In observations on virgin and gravid and lactating guinea pigs, it was found that the cortical substance of the suprarenals increased regularly in size and wt. during lactation. V. believes that the cortex of the suprarenals represents an important factor in the development and general nutrition of the animal organism. L. W. RIGGS.

G. PATHOLOGY.

H. GIDEON WELLS.

Combined action of the liver and spleen. Study of the function of the spleen. L. ASHER AND G. EBNÖTHER. *Bern. Zentr. Physiol.* 30, 61-4(1915).—Liver exts. cause hemolysis and hemoglobin destruction; this process is greatly accelerated by the addition of splenic exts. The substances that cause hemolysis and hemoglobin destruction are different, the former being thermolabile, the latter thermostable. The splenic ext. itself does not give these reactions but only accelerates the action of the liver exts.; this property is specific for splenic exts. E. M. FRANKEL.

Functional tests in experimental tartrate nephritis. A. C. POTTER AND E. T. BELL. *Am. J. Med. Sci.* 149, 236-47(1915).—By subcutaneous injections of tartaric acid it is possible to produce in rabbits a form of acute nephritis in which the great majority of the convoluted tubules are necrotic and the rest fatty and granular, while the glomeruli and collecting tubules may be automatically intact. Evidence obtained from expts. with such kidneys suggests that a phthalein, indigo-carmin and methylene blue are excreted exclusively by the convoluted tubules, that KI and lactose may be excreted by the glomeruli, and that hemoglobin is excreted mainly by the tubules, but may pass slowly through the glomeruli. TULA LAKE HARKEY.

Studies on the concentration of blood-sugar in health and disease as determined by Bang's micro-method. ARTHUR H. HOPKINS. *Am. J. Med. Sci.* 149, 254-67 (1915).—In health a moderate rise in the amt. of blood-sugar occurs after feeding 100 g. of glucose. There is no constant blood-sugar level at which sugar appears in the urine. Where a disturbance in carbohydrate metabolism exists, there may be a normal sugar concentration associated with a most pronounced alimentary hyperglucemia. In diabetes alimentary hyperglucemia is pronounced and continues for a longer period. Pancreatic, nephritic and pituitary cases all give high figures for blood

sugar after feeding glucose. Edema and hepatic congestion do not influence blood sugar values. There is a rise in blood sugar in pneumonia, and this rise may be present in the absence of fever; apoplexy, typhoid and tuberculosis, in the presence of fever, and some cases of cancer also cause a rise in the amt. of sugar in the blood. The test affords a practical method for early diagnosis and control of dietary therapeutics.

TULA LAKE HARKEY.

Why the modern chemico-parasitic theory is untenable. RAGNAR ECKERMANN. Malmö, Sweden. *Dental Record* 36, 10-4(1916).—Seventeen reasons are advanced to prove untenable the chemico-parasitic theory of dental caries. "Whatever may be the primary cause of caries, a chemico-parasitic process is in any case excluded." The teeth are affected by such a process *after* the dental front is broken, and a way is opened through the enamel, or the gingival part of the tooth is exposed. JOS. S. HEPBURN.

The resistance of the blood corpuscles and the antihemolytic power of the blood plasma of splenectomized animals. ANDRÉ ROCCA VILLA. *Arch. méd. exper.* 26, 508-72, 636-726(1915).—The first part of the paper gives an extended historical discussion and a detailed description of the technic used. The second part gives exptl. results, theories and conclusions. R. worked with splenectomized dogs and rabbits, and studied the resistance of the red blood cells to hemolysins and the antihemolytic power of the blood plasma, before and after the removal of the spleen, and *in vivo* and *in vitro*. He employed the following hemolytic and antihemolytic substances: distd. H₂O, hypertonic NaCl solns., saponin, biliary salts (sodium glycocholate), heterogeneous sera (hog and eel), antidog and antirabbit hemolytic sera, head ext. of leeches, and staphylolysin. He concludes that the spleen plays an important part in physiological and pathogenic hemolysis. In every instance removal of the spleen increased the resistance of the red blood cells to hemolytic agents and increased the antihemolytic power of the plasma, even though the mechanism of the action of the various antigens employed was very different. R. thinks that hemolysis is based on physico-chemical changes and that the hemolytic substances absorb something and thus allow the proteins to dissolve. A detailed discussion of the theories as to the mechanism of hemolysis is given.

JOHN T. MYERS.

A case of pancreatic insufficiency. E. I. SPRIGGS AND A. J. LEIGH. *Quart. J. Med.* 9, 11-42(1915).—A patient with the symptoms of chronic disease of the pancreas was under observation 21 weeks in 5 periods extending over 18 months. The urine and feces were analyzed for 64 days and compared with the intake of food. Trypsin could not be detected in the feces. Formalin-hardened gelatin capsules containing CHI₃ were not digested. Diastase was present in the urine in normal amts. An av. of 1260 g. of feces was passed per day, on admission. With the reduction of unassimilable forms of fat in the food the quantity was reduced to 800 g. An av. of 302 g. of fat per day was lost in the stools on admission, thus from 25 to 59% of the calorific energy of the food being lost. The proportion of fat in the food which was lost in the feces varied from 55 to 99%. The fat of milk was much better absorbed than that of butter, meat, or cod liver oil. The percentage absorbed was less when a large quantity was given. The proportion of total fat in the feces which had been split and was in the form of fatty acids and soaps was rather more than normal throughout, the av. of 54 days figures being 87%. Variations and nature of the fat did not affect fat splitting appreciably. Nearly half the N of the food appeared in the feces. Sugar was present in the urine, but there was no evidence of acidosis. Various ferments were used in the exptl. periods. All except fresh pancreas and trypsinogen irritated the intestinal tract. With trypsinogen there was improvement in the absorption of fat, and with pancreon improvement in the absorption of N. The article has an excellent bibliography.

JOHN T. MYERS.

Anti-phenol serum. JANINA WISZNIEWSKA. *Compt. rend.* 161, 609-12(1915).—A substance was isolated from the products of intestinal putrefaction of proteins which reacts positively with phenolic reagents but does not correspond to any known phenol deriv. It is alkaline and possesses some characteristics of the leucomaines. When administered to animals with food it produced definite sclerotic effects upon the arteries. When injected intravenously into a horse, an antibody was produced in the horse serum which was employed with therapeutic success. W. A. PERLZWEIG.

The Abderhalden reaction in glanders. R. VLADESCO AND J. POPESCU. Bucharest. *Compt. rend. soc. biol.* 77, 586-7(1915).—In view of the observation of Stephan that the proteolytic action of serum disappears after heating for $\frac{1}{2}$ hr. at $53-56^{\circ}$ and reappears after addition of complement, V. and P. have repeated with due precautions their former expts. in which uncertain or negative results were obtained. The horses from which the blood was withdrawn were subjected to a previous fast of 24-36 hrs. and the serum was then dialyzed for 6-10 hrs. in order to eliminate dialyzable substances which give the reaction with ninhydrin; the serum was next inactivated at $53-56^{\circ}$ for $\frac{1}{2}$ hr. and guinea-pig complement was added in the proportion of 0.1 cc. to 1.0 cc. serum. Glanders bacilli obtained in the prepn. of mallein were employed as substrate. Ninhydrin was used in a diln. of 1:500 in the proportion of 1 cc. to 10 cc. dialysate. The results indicate the presence of sp. enzymes in the serum of glanderous animals. It was frequently observed that the serum of glanderous horses became opalescent on being heated to $53-56^{\circ}$. H. S. PAINÉ.

Residual nitrogen of the blood under physiological conditions and its behavior in nephritis, uremia and eclampsia, as well as its significance in the testing of kidney function. H. HOHLWEG. Giessen. *Med. Klin.* 11, 331(1915); *Zentr. Biochem. Biophys.* 18, 261(1915).—Purely unilateral kidney affections do not cause an increase in the residual N content of the serum; practically normal values of 40-61 mg. per 100 cc. are found. A normal residual N value simply shows, therefore, that at least 1 kidney is healthy and capable of function. After extirpation of 1 kidney the residual N values become normal in 4-6 weeks after the operation in case the remaining kidney is sound; when the latter is affected increased residual N values are observed for many weeks following the operation. The residual N value is increased in patients with bilateral renal suppuration or at least toxic impairment of the 2nd kidney. Residual N values of 75 mg. per 100 cc. do not contra-indicate extirpation of the affected kidney, since the process in the remaining kidney is capable of restoration or at least of amelioration. A residual N value of 100 mg. per 100 cc. indicates severe, irreparable alteration of both kidneys and forbids extirpation. H. S. PAINÉ.

Diazo and urochromogen reactions in pulmonary tuberculosis. A. N. SINCLAIR. Honolulu. *J. Am. Med. Assoc.* 66, 247-8(1916).—From a study of 146 cases S. arrives at results which disagree with those of Schaffle (cf. C. A. 9, 92) in that the negative diazo and positive urochromogen reactions proceed at low instead of high death rate; also when both reactions were positive the diazo reaction did not disappear before death. L. W. RIGGS.

Principles underlying the use of vaccines, bacterins, antitoxins and immune serums as agents for the prevention and cure of infectious diseases. F. E. STEWART. *J. Am. Pharm. Assoc.* 4, 1440-50(1915).—A review. M. I. W.

Nature and quantitative determination of reducing substances in normal and pathological cerebrospinal fluid. O. M. SCHLOSS AND L. C. SCHROEDER. New York. *Am. J. Dis. Children* 11, No. 1(1916); *J. Am. Med. Assoc.* 66, 219.—The results for normal fluids were obtained from 45 children on whom lumbar puncture was done as a diagnostic procedure. The reducing substance appears to be a fermentable dextrorotatory sugar, probably dextrose, which varied in amt. from 0.034 and 0.139%.

The belief that the reducing substance in the fluid is pyrocatechol is not supported.

L. W. RIGGS.

New researches on the proteases of leucocytes, in connection with Abderhalden's work on protective enzymes. NOEL FIESSINGER AND L. ROWDOWSKA. *Arch. mbd. exper.* 26, 459-81(1915).—F. and R. used the methods of Abderhalden in the study of the proteolytic enzymes of leucocytes for the purpose of studying their mode of digestive action and their physiological function. The leucocytes were obtained by collecting, from various human lesions pus, as free from blood as possible, and washing in physiological NaCl soln. by centrifugalization and decantation until free from amino acids by the ninhydrin test. As antigen they used human placenta, kidney, liver, and red blood cells, boiled and washed. They decide that the decompn. of the albumin by the protease occurs without the presence of a foreign albumin, even in high dilns. of the leucocytes. The protease was not specific. They conclude that the dialysis methods are inaccurate and very difficult to carry out, sometimes giving contradictory results. Therefore they made some expts. using the chem. method of Sørensen and Ronchese as modified by Bournigault and Bith. This method shows the strong digestive action of the proteases of the polymorphonuclears. This action manifests itself on the protein of the leucocytes themselves. It is more active in a concd. suspension of leucocytes. The formation of amino acids is proportional to the number of polymorphonuclears in the pus. By this method egg albumen did not hinder the reaction as it did when the less accurate dialysis method was used. As shown by both methods, heating to 80° for 10 min. attenuated the protease, and 1 min. at 100° destroyed it. The bibliography is brief.

JOHN T. MYERS.

The Wassermann and luetin reactions in leprosy. WM. FLETCHER. *J. Hyg.* 15, 102-28(1915).—A comparison of the Wassermann and luetin reactions was made, using a group of 100 lepers and 110 non-leprous persons. F. concludes that leprosy may cause complement deviation, but that it does not render the luetin reaction positive. A bibliography is appended.

JOHN T. MYERS.

A contribution to the experimental study of fever. J. L. JONA. *Lister Inst. J. Hyg.* 15, 169-94(1915).—The dried bodies of *B. coli* and *B. typhosus* were used, also "pyrotoxin" made according to Sebastian, as follows: heat a 3-day broth culture for 15 min. at 100°, make it acid, let it stand 15 days, ppt. it with Pb(OAc)₂ and remove the excess Pb with a 10% soln. of Na₂SO₄. Rabbits were injected in various ways. A definite rise in temp. is obtained by the injection of 0.000004 g. of bacterial substance in a small quantity of Ringer soln., and a definite collapse or even death with 0.002 g. The substance or substances in the bacteria responsible for the rise in temp. are either of a colloidal nature or adherent to colloids, and may be almost entirely sepd. by a colodion filter. They are not destroyed by boiling nor by dry heat at 110°. They are sol. in water or saline solns., insol. in ether and not affected by prolonged contact with it. Their potency is diminished by long contact with abs. alc. but they are insol. in it. The exact chem. nature of the substance is not known; it does not give the protein reactions. Autolysis of the bacterial bodies can yield this fever-producing substance. Ca forms an inert salt with it. The rise in temp. produced lasts a few hrs. and is principally due to a diminution in heat loss, heat production remaining sometimes unaffected and sometimes increased. The fall in temp. in collapse when large doses of the bacterial ext. were given is due to a diminution in heat production, heat loss being also diminished. In animals in which the brain stock had been severed distal to the optic thalamus no rise of temp. occurred after an ordinary pyretic dose. A two-page bibliography is given.

JOHN T. MYERS.

Toxins of intestinal worms. D. E. PAULIAN. *Presse medicale* 23, No. 49(1915); *J. Am. Med. Assoc.* 65, 1954.—Guinea pigs were injected with alc. exts. of various

intestinal parasites. Other tests were made with macerations of the bodies of the parasites. Severe toxic action followed the injections. P.'s findings confirm those reported by others, except that he never detected the lesions described by Rachmanov in the nervous elements. The organs most affected were the spleen, kidneys and liver. The suprarenals were always hyperemic and with intertrabecular hemorrhages.

L. W. RIGGS.

Etiology of dental caries. CARLO BRÜGNATELLI. Milan. *Thesis, Milan* (approx. 400 pp.), 1914; *Zentr. Biochem. Biophys.* 18, 96-7(1915).—B. attempted to ascertain whether saliva contains lactic acid and whether the 1st phase of dental caries, i. e., decalcification of dental tissue, can be attributed to the action of this acid. His results confirm the observations of Miller and show that the enzymic action of the saliva only extends to the formation of sugar. B. concludes that neither lactic acid, KCNS, nor the oxidizing enzymes of the saliva play any essential part in the process of dental caries, although they may favor the inception of the latter. From the material of carious teeth B. invariably isolated a polymorphic bacillus which could not be identified with known forms.

H. S. PAINE.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Mechanism of the action of aconite on the cardiovascular and respiratory systems.

ALFREDO CHISTONI. Univ. Naples. *Arch. farm. sper.* 20, 411-49(1915).

A. W. DOX.

The genesis of cardiac automaticity. DARIO MAESTRINI. Univ. Genoa. *Arch. farm. sper.* 20, 467-80(1915).—The application of cocaine-HCl (6%) to the sinus of the frog heart arrests the cardiac rhythm in a few minutes. During this arrest the heart is in abs. repose. When applied to any other region of the heart (auricle or ventricle) cocaine does not appreciably modify the rhythm. Successive applications do not produce as great a response as the first. The auricular contractions are the last to disappear and the first to reappear. Atropine is not suitable for restoring the cardiac rhythm after cessation of the latter through the action of cocaine. A. W. D.

The uric acid solvent power of urine containing hexamethylenetetramine as compared with that of normal urine. HOWARD D. HASKINS. Univ. Oregon. *Arch. Intern. Med.* 16, 1055-66(1915).— $(\text{CH}_2)_6\text{N}_4$ exerts a uric acid-solvent action in the urine only after the administration of excessive doses.

I. GREENWALD.

Some observations on the elimination of hexamethylenetetramine. K. GEORGE FALK AND KANEMATSU SUGIURA. New York City. *J. Pharmacol.* 8, 39-51(1916).—The object of this study was to observe the behavior of the drug in the human organism under normal and pathological conditions. A method for the quant. estn. of $(\text{CH}_2)_6\text{N}_4$ is described; it is carried out essentially as follows: To 50 cc. of the soln. is added, with stirring an alc. I soln. containing 3.6 g. I in 100 cc. 95% alc. Protein or other substances reacting with I must be excluded. If $(\text{CH}_2)_6\text{N}_4$ is absent, no ppt. is formed at first, but on further addition bluish black I ppts. If $(\text{CH}_2)_6\text{N}_4$ is present, a ppt. (at first brownish yellow, than reddish to dark brown) is formed. About 20% excess I is used, the amount needed being judged by the formation of the ppt.; as a rule 5 to 8 cc. of I are required. After all the I is added, the mixt. is allowed to stand 10 min. with occasional stirring; then it is filtered through a Gooch crucible with asbestos mat; the ppt. is washed 5 to 10 times with cold H_2O . The ppt. and crucible are dried *in vacuo* over CaCl_2 to const. wt. and weighed as tetraiodide. Better than the gravimetric procedure is titration of the I with 0.04 N $\text{Na}_2\text{S}_2\text{O}_3$ soln. For this method, the ppt. and crucible are transferred to a beaker, 50 cc. H_2O and 3 cc. glacial HOAc added, and the mixt. titrated with the $\text{Na}_2\text{S}_2\text{O}_3$, a few cc. starch soln. being added toward the end. If the liquid contains protein matter (albuminous urine),

an equal vol. of MeOH is added, the mixt. allowed to stand 1 to 3 hrs. at room temp., filtered by decantation through folded filter paper, evapd. to $\frac{1}{2}$ the vol. in a current of air or under diminished pressure, 1 soln. added and the detn. carried out as described above. The presence of glucose does not interfere; the error in aq. solns. is about 10%, in urine not more than 5%. The phloroglucinol test was used for free HCHO. The excretion in normal individuals was as follows: after 2 g. doses 81, 71 and 40%; after 1 g. doses in a larger number of expts. total excretion ranged from 11 to 74%; with smaller doses (0.33 to 0.67 g.) excretion was irregular and ranged from 10 to 66%. In general, the amt. normally excreted was found to be greater the lower the sp. gr. of urine. $(\text{CH}_2)_6\text{N}_4$ always appeared in the first hour's urine, and the amt. increased and reached a max. during the 2nd and 3rd hrs.; practically no more was excreted after 12-14 hrs. Certain pathological conditions of the kidneys appeared to greatly decrease the excretion of $(\text{CH}_2)_6\text{N}_4$, which ranged from none or a trace up to 88%. In some cases, when excretion of the drug was low, the phthalein excretion and non-protein N of the blood were within normal limits; in other cases the results with all the tests were practically in the same direction. HCHO was demonstrated in 20 out of 32 urines examd.; but only in 2 of these was enough present to indicate bactericidal action. In the human series, no deleterious action from the drug or HCHO in urine was observed. Following the administration of 3 g. per day for 4 days in a dog, hematuria was observed on the 4th day; this disappeared when no more $(\text{CH}_2)_6\text{N}_4$ was administered.

P. J. HANZLIK.

The comparative pharmacologic action of ethylhydrocuprein (optochin) and quinine. MAURICE J. SMITH AND BERNARD FANTUS. *Ann Arbor, Mich. J. Pharmacol.* 8, 53-74(1916).—Ethylhydrocuprein has been given considerable publicity abroad, but no systematic study of its pharmacologic action has been previously made, which might indicate its possible uses, limitations and dangers. S. and F. have found ethylhydrocuprein to be more toxic than quinine for unicellular organisms (*Stylonychia*), frogs and white mice. It is more irritating than quinine to rabbit conjunctiva and the local anesthesia produced by it here is also greater; depression of the central nervous system in frogs, rabbits and mice is about the same as with quinine; it has a greater toxic action on cardiac muscle than quinine, depressing both systole and diastole; blood pressure is lowered less by it than quinine, but a greater vasoconstriction is produced in frog vessels and those of dog kidney than with quinine; uterine action is essentially like quinine; as an antipyretic it is uncertain in small doses and in moderate doses is less efficient than quinine. Intravenous administration should be used cautiously in clinical cases. A fatal case treated with ethylhydrocuprein in which the drug probably played a part is reported.

P. J. HANZLIK.

Aconite as a vasodilator. WILLIAM H. THOMSON. *Am. J. Med. Sci.* 149, 77-8 (1915).—T. objects to all nitrites because their vasodilating effects are too transient. He regards aconite as the most efficacious vasodilator. The most important action of aconite in interstitial nephritis is the increase in the elimination of urea.

TULA LAKE HARKEY.

Use of fluid extracts of umckaloabo and chijitse in the treatment of pyorrhea avelaris. H. J. KAUFFER. New York City. *Dental Cosmos* 57, 1366(1915).—These South American herbs, which are employed as infusions by the natives as a specific for all diseases of an infectious nature, are non-toxic, and apparently do not contain any known alkaloid. A 5% solution of their tincture was a bactericide, and inhibited growth of a mixed culture of pyogenic bacteria from the pocket of a case of pyorrhea avelaris. A 10% solution of their tincture destroyed these bacteria in 10 min. Irrigation of pyorrhea pockets with the 10% solution of their tincture exerted a marked curative action with gradual diminution of pus.

JOSEPH S. HEPBURN.

Action of atophan on the kidney function. GEORG EISNER. *Deut. Arch. klin. Med.* 118, 125-8(1915).—The excretion of NaCl and N after giving 8 patients atophan was plainly decreased; it rose to normal when the atophan was stopped. In several cases there was later a compensatory increase. The excretion of uric acid was increased under the influence of atophan. A supposed analogy between the action of atophan and Ca was not established. The use of atophan as a functional renal test was uncertain.

JULIAN H. LEWIS.

The action of atropine and scopolamine on the cat eye. GEORG JOACHIMOGLU. Univ. Berlin. *Berl. klin. Wochschr.* 52, 910(1915).—The smallest dose of atropine sulfate which causes mydriasis, when dropped into a cat eye, is 0.000245 mg. The smallest dose of scopolamine-HBr is 0.00001855 mg. The scopolamine is therefore approx. 10 times more active than atropine.

JULIAN H. LEWIS.

Chemotherapeutic studies on the intravenous application of antimony trioxide in experimental trypanosome infections. G. L. HOFFMANN. Bern. *Z. Hyg.* 80, 261-78(1915).—The intravenous injection of Sb₂O₃, suspended in sugar, gum arabic, or sugar and gum arabic led to a sterilisans magma in rabbits experimentally infected with trypanosomes (nagana and dourine).

JULIAN H. LEWIS.

Pepper in the prophylaxis and treatment of filariasis. J. A. ROBERTSON. *Brit. Med. J.* 1915, II, 535.—Because of the freedom from filariasis of the Carib Indians, who consume large quantities of pepper, R. concludes that piperine is a prophylactic against this disease. Expts. with capsicum in filarial fever and lymphangitis support this view.

A. H. RAHE.

Action of radium on transplanted tumors of animals. F. C. WOOD AND F. PRIME, JR. New York. *Ann. Surg.* 62, No. 6(1915); *J. Am. Med. Assoc.* 66, 59.—Three factors only are important in the action of Ra on tumors: time of exposure, amt. of Ra, and distance between the Ra tube and the tumor tissue. The removal by filters of the larger part of the β rays diminishes proportionately the effect of the Ra, but the effect of the γ rays is in accordance with the same general law which governs the β rays. When only pure γ rays are used the necessary exposure is 8 times as long as that required when γ and hard β rays combined are employed, but as the latter are largely absorbed by 1 cm. of tissue, γ rays alone must be used for all deep work.

L. W. RIGGS.

Manufacture of nitrous oxide for anesthesia. A. R. WARNER. Cleveland. *J. Am. Med. Assoc.* 65, 1973-6(1915).—The gas as first manufactured frequently gave rise to serious toxic symptoms which were entirely prevented by bubbling the gas through concd. H₂SO₄. The toxic substances were found in the acid as ammonium salts, and are believed to exist in the gas as hydrazines or hydroxylamines. Full specifications for the construction, operation and cost of a N₂O plant suitable for a hospital are given. With the improvements noted it is practical, by skilled hands, to administer N₂O without the least cyanosis or the unpleasant effects which follow the use of Et₂O and CHCl₃.

L. W. RIGGS.

Occupational injuries due to radium. THOMAS ORDWAY. Albany Med. Coll. *J. Am. Med. Assoc.* 66, 1-6(1916).—Descriptions with photographic illustrations are given of 9 cases of Ra injury among physicians, medical attendants and physicists. The results of blood exams. are tabulated, showing in most cases a large increase in the lymphocytes (cf. Gudzent and Halberstaedter, *C. A.* 8, 2197). Marked changes may occur on the fingers of those engaged in routine work with radioactive substances, consisting chiefly of flattening of the characteristic ridges, thickening and scaling of the superficial layers of skin and even atrophy and intractable ulceration. To avoid injury special forceps and vises have been devised for use in handling the tubes, also

screening applicators to protect the operator. In routine work there should be a rotation in the staff so that persons affected can be freed at least for a time from such work.

L. W. RIGGS.

Action of "autolysin" on mouse tumors. F. C. WOOD. New York. *J. Am. Med. Assoc.* 66, 94-5(1916).—Twenty-one animals bearing spontaneous tumors were treated with "autolysin" supplied by Beebe and Horowitz. The prepn. appeared to be non-toxic, even in very large doses, to normal animals, and in small or large doses was without effect upon malignant tumors of mice.

L. W. RIGGS.

Resuscitation by means of preserved erythrocytes in experimental illuminating gas asphyxia. W. H. BURMEISTER. Univ. Ill. *J. Am. Med. Assoc.* 66, 164-7(1916).—A general review and discussion of the treatment of CO asphyxia is given with 18 references to the literature. In B.'s expts. the blood used was drawn from the femoral artery in case of dogs and received directly into a sterile flask at the rate of 225 cc. of blood to 25 cc. of 10% aq. Na citrate soln. To this were added 250 cc. of sterile Ringer soln. containing 2.5% of dextrose. After gently mixing its contents the flask was placed in the dark at 4° until the time of transfusion, when its contents were centrifuged and the top layer together with the layer of white corpuscles removed, leaving 125-150 cc. of erythrocyte suspension which would keep 3 or 4 weeks. Rabbit blood drawn by cardiac puncture was treated in a similar manner, except that 10 times as much Ringer soln. was used, the corpuscles remaining intact for 10 weeks. Full details are given for the asphyxiation of 40 dogs and 20 rabbits, and of the subsequent treatment of 15 of the dogs and 12 of the rabbits by injection of erythrocytes, the remaining animals being used as controls. This treatment proved successful in 75% of the cases in which transfusion was begun while cardiac contraction could still be elicited. A number of the control animals were treated by other methods of resuscitation. The establishment of emergency stations where human erythrocytes can be obtained is recommended.

L. W. RIGGS.

Has secretin a therapeutic value? A. J. CARLSON, *et al.* Univ. Chicago. *J. Am. Med. Assoc.* 66, 178-85(1916).—An extensive review of literature is given with 60 references. The author's expts. show that secretin is quickly destroyed by the gastric juice and by trypsin, that it is not absorbed in active form from the alimentary tract, and is without action when taken by the mouth. The presence of secretin or prosecretin cannot be demonstrated in the commercial prepn., "Secretogen," "Elixir secretogen" and "Duodenin" even when the therapeutic dose is given intravenously. In the case of "Secretogen" an intravenous injection of 100 times the therapeutic dose reveals occasionally a trace of secretin. "There is as yet no reliable evidence that lack of secretin is a primary or important factor in any disease. Even if this should be established, secretin therapy to be effective must be intravenous. Secretin has not yet been prepd. in sufficiently pure state to render possible intravenous injection in man without injurious effects." The results of the exptl. work are shown in 8 tables and 9 tracings.

L. W. RIGGS.

Comparative toxicity of various preparations of mercury. J. F. SCHAMBERG, *et al.* Phila. *J. Cutaneous Dis.* 33, No. 12(1915); *J. Am. Med. Assoc.* 66, 62.—Toxicity of Hg compds., whether mineral or organic, is directly proportional to the amt. of Hg present. Molecular structure appears to have little influence upon toxicity. HgCl₂ administered intravenously was fatal on the av. above 2 mg. per kg. of body wt.; intramuscularly it was fatal on the av. above 6 mg. per kg. Insol. prepn. of Hg were absorbed at a rate of a little over 1% of the injected amt. per day. At the end of 6 weeks 50% of the insol. Hg prepn. may be unabsorbed at the site of injection; hence the injection of usual doses of insol. Hg compds. at weekly intervals must lead to an accumulation of Hg in the tissues. Hg has a great affinity for the cells of the kidney,

this organ being one of the earliest involved in Hg intoxication. Calcification of the degenerated tubular cells has been found within 48 hrs. after administration of Hg, and always occurs in severe Hg nephritis, irrespective of the compd. administered, or the route of injection.

L. W. RIGGS.

Action of peptone on the heart, vessels, and blood pressure. S. A. PISSEMSKY. *Russ. Vrach* 14, No. 38(1915); *J. Am. Med. Assoc.* 65, 2128.—The peptone was passed through the vessels in solns. of 1:200, 1:1000, and 1:10000. The last 2 solns. caused weakening of cardiac contractions, while the 1:200 stimulated the heart to contract, the rhythm remaining uninfluenced. The strong soln. caused marked dilatation of the coronary arteries. The action on the peripheral vessels was studied on rabbit ears with the method of Kravkov. The action was vasoconstricting with all concns., and with any kind of peptone. In the vessels of the isolated kidneys of rabbits the blood pressure remained unchanged or rose, contrary to the observation with dogs in which the same dose (0.5 g. per kg. of body wt.) causes a fall in blood pressure.

L. W. RIGGS.

Case of boric acid poisoning. P. WILLSON. Washington. *Wash. Med. Ann.* 14, No. 6(1915); *J. Am. Med. Assoc.* 66, 63.—An 8 weeks old infant received 3 oz. of a satd. soln. of H_2BO_3 by mistake, nursed, vomited during nursing and received 3 oz. more of the acid. A severe gastro-enteritis followed, accompanied by rapid loss of wt. and the appearance of a slight miliary eruption. Peeling was completed in about 10 days, a rapid recovery following.

L. W. RIGGS.

Influence of oxyquinoline derivatives on purine metabolism and their therapeutic application. T. BRUGSCH AND R. WOLFFENSTEIN. Berlin. *Berlin klin. Woch.* 52, 157(1915); *Zentr. Biochem. Biophys.* 18, 253(1915).—The influence of oxyquinoline on excretion of uric acid in man cannot be detd., inasmuch as the compd. is poisonous. Expts. were therefore made with o-oxyquinoline salicylate which had the effect of reducing the amt. of uric acid excreted. Amts. of 3-4 g. per day in doses of 0.5-1.0 g. continued for 1 week were effective in this respect. No accumulation of uric acid in the blood was observed.

H. S. PAINÉ.

Pathological-anatomical investigation of Basedow's disease. H. RAUTMANN. Chemnitz. *Mitt. Grenzgeb.* 28, 489-618(1915); *Zentr. Biochem. Biophys.* 18, 111-2(1915).—Intoxication, rather than infection, is the primary factor in the etiology of Basedow's disease; a functional disturbance of the internal secretion is probably the source of the intoxication.

H. S. PAINÉ.

Synergic action of vasoconstrictors in local anesthesia. J. BURMANN. *Schweis. Apoth. Ztg.* 53, 478-9(1915); *Pharm. J.* 95, 360(1915).—Epinephrine in diln. of 1:1000 is added to advantage as vasoconstrictor to cocaine, stovaine, alypine or novocaine, etc. As its action in this diln. lasts only a short time, and greater concn. would be toxic, B. recommends that it be combined with uteramine ($p\text{-EtNHC}_6\text{H}_4\text{OH.HCl}$) which has 0.01 the activity of epinephrine. An efficient injection for dental use consists of novocaine 0.03 g., epinephrine 0.00005 g., uteramine 0.005 g., physiological soln. 1.0 cc. in sterilized 1 cc. ampoules. The dose is 1 to 2 cc. of this prepn.

S. WALDBOTT.

Thorium X and uric acid. E. KUZNITZKY. Breslau. *Berlin klin. Wochschr.* 52, 159(1915); *Zentr. Biochem. Biophys.* 18, 227(1915).—K. tested the action of Th X on uric acid in a case of deposition of uric acid crystals in the cornea of each eye. Five g. Th X were injected intravenously at weekly intervals. No decrease in uric acid was observed either before or after the injections and it appears that Th X has no direct action on uric acid.

H. S. PAINÉ.

Content of sugar in the blood under the influence of cocaine. E. W. E. SCHEAR. Columbia Univ. *Am. J. Physiol.* 38, 269-73(1915).—Injections of cocaine into cats

may cause a decrease in blood sugar provided the animal does not show excitement at, or subsequent to, the injection. When excitement is manifest blood sugar is markedly increased. Indirectly, cocaine may cause hyperglucemia by inducing an excited condition in the animal; hence the use of the drug in drawing blood for sugar analysis is attended by an element of doubt.

J. F. LYMAN.

Esters of tertiary trichlorobutyl alcohol and their pharmacology (WOLFFENSTEIN)
10.

I. ZOÖLOGY.

R. A. GORTNER.

Regeneration of the ovaries of *Polycelis nigra*. JULES ZWEIBAUM. *Arch. Entwickl. Organ.* 41, 430-70(1915); *Zentr. Biochem. Biophys.* 18, 269(1915).—Regeneration of the ovaries of *Polycelis nigra* is independent of the nutrition. Light accelerates regeneration at temps. (14-16°) which are favorable thereto; regeneration is inhibited in the dark at these temps. A salt medium has in general no definite influence. NaCl has a sp. retarding action on the sexual differentiation of germ cells. CaCl₂ and Fe₂Cl₆ have an accelerating action on the increase of oögonia. As₂O₃ produces a considerable stimulation of regeneration. A slight acid content promotes regeneration, while an alk. reaction retards it somewhat.

H. S. PAINE.

Acid sensitiveness of euglena. K. LINSBAUER. *Graz. Oest. bot. Z.* 65, 12-21 (1915); *Zentr. Biochem. Biophys.* 18, 99(1915).—Expts. with *Euglena intermedia* var. *Klebsii* Lemm. showed that the critical concn. for various organic acids (succinic, lactic, formic, malic, etc.) varies within rather wide limits; glycolic and citric acids constitute the 2 extremes for the acids investigated, the relative critical concns. being 17.3 and 3, resp. The critical concn. (expressed in % by wt.) for fatty acids increases with increasing mol. wt., while the toxicity varies in inverse ratio. The OH group of hydroxy acids is only capable of effecting a distinct decrease in toxicity in the case of monobasic acids, this observation being somewhat contrary to that of J. Loeb; no decrease in toxicity was observed in the case of dibasic acids. This result is probably connected with the fact that the molar limiting concn. decreases rapidly with increasing mol. wt. of hydroxy acids. Monohydroxy acids have the slightest toxic action, while the greatest toxicity is exhibited by the tetrahydroxy, tribasic citric acid; while the mol. wts. of glycolic and citric acids, the end members of the series investigated, are as 1:2.5, the reciprocal molar limiting concns. are as 1:8.

H. S. PAINE.

Influence of ultraviolet rays on the regeneration of the pigmentary apparatus of Triton. L. TORRACA. Naples. *Inat. Monatsschr. Anat.* 31, 410-33(1915); *Zentr. Biochem. Biophys.* 18, 104(1915).—T. discusses exhaustively the injury to the tissue which is caused by ultraviolet rays.

H. S. PAINE.

Physiological destruction of erythrocytes in birds. PRESTON KYRS. Univ. Chicago. *Inat. Monatsschr. Anat.* 31, 542-50(1915); *Zentr. Biochem. Biophys.* 18, 273(1915).—K. found, in the liver and spleen, cells of a definite type which gave a distinct Fe reaction. This is probably a case of phagocytosis of erythrocytes and it appears to be the normal function of these cells to destroy erythrocytes, thus liberating Fe.

H. S. PAINE.

Heat coagulation of muscles of northern and southern frogs. R. HOPKINS AND G. MANN. Tulane Univ. *Inat. Monatsschr. Anat.* 31, 552-8(1915); *Zentr. Biochem. Biophys.* 18, 265(1915).—The muscles of northern frogs exhibit heat rigor and coagulation at higher temps. than do the muscles of southern frogs; nicotine and atropine have no influence on the varied behavior with respect to temp. Acids which are formed in the muscle as a result of fatigue cause coagulation to occur at a lower temp.

H. S. PAINE.

Asphyxia and narcosis. A. MONTUORI. Rome. *Z. allgem. Physiol.* 17, 18-27 (1915); *Zentr. Biochem. Biophys.* 18, 290-1 (1915).—Tadpoles of *Bufo vulgaris* which were gradually habituated to temps. as high as 18° by daily temp. increases of 2° became more resistant to asphyxiation and showed a simultaneously increased resistance to narcotics. M. concludes that there is a definite connection between narcosis and asphyxiation.

H. S. PAINE.

Origin of recent forms of melanism in butterflies and the significance of the Hamburg forms in the explanation thereof. K. HASEBROEK. Hamburg. *Zool. Jahr., Abt. System. Geogr. Biol. Tiere* 37, 567-600 (1914); *Zentr. Biochem. Biophys.* 18, 99-100 (1915).—The origin and distribution of melanistic forms of butterflies are closely connected with the extension of industries and are probably primarily dependent upon the greatly increased production of smoke and flue gases. It is not certain what chem. influences have played a part in elaborating the hypertrophy of black pigment as a hereditary characteristic. The SO₂ with which the atm. of industrial sections (especially in and around large cities) is impregnated probably plays a considerable role in view of its affinity for O and the consequent inhibition of oxidative processes (which has already been shown to cause an increase in the black pigment of butterfly scales).

H. S. PAINE.

Vital staining in insects by "soluble carmin." A.-CH. HOLLANDE. *Compt. rend.* 161, 578-80 (1915).—Acid and alkaline solns. of carmin behave differently when injected into insects. The acid-carmin compds. are absorbed chiefly by digestive cells, leucocytes, cells of the pericardium, and renal cells. The alkaline carmin compds. are absorbed only by leucocytes and pericardial cells. While the "acid carmins" only traverse the cells, the alk. carminates may remain in the cells for many months. This latter fact H. explains by the transformation of the alk. carminate into pure carmin, which is insol. in H₂O and alc., but is sol. in dil. acids and bases. It is because of the amphoteric properties of carmin compds. that living cells absorb them with ease.

W. A. PERLZWEIG.

Genetic factors and enzyme action. RICHARD GOLDSCHMIDT. Yale Univ. *Science* 43, 98-100 (1916).—After reviewing the work of others G. gives an account of his observations on the pigmentation of the wings of the moth *Lymantria monacha*. All gradations were found between a white animal with the characteristic zigzag bands and a completely black one. Breeding expts. show that these intermediates are to be explained by combinations of some partly sex-linked factors for pigmentation and "there corresponds to every combination of factors, an enzyme reaction, definite in quantity." A study of the different grades of intersexuality produced by breeding of hybrids shows that every step leading from a normal female through the different grades of "intersexes" to a male or *vice versa*, is characterized by a definite intermediate step of wing pigmentation. In the different intersexes a certain amt. of pigment-producing oxidase, parallel to the quant. behavior of the sex factors, is furnished by the veins, varying from 0 in the female to 100% in the male. The results of this study confirm independently the conclusions of others, "that the hereditary factor is a determiner for a given mass of enzymes; and that a quant. difference in the potency of hereditary factors causes a parallel quantitatively different enzyme production."

L. W. RIGGS.

The tension of oxygen in the body fluids of the coelenterata in the sea and in aquaria. E. LOUIS BACKMAN. *Upsala Läkare förenings Föreläsningar* 20, 287-302 (1915).—The body fluid of the *Rhizostoma cuvieri* is osmotically isotonic with the sea water but not with regard to the O₂, which is less within the animal, indicating O respiration in its cells. B. is of the opinion that the gastrovascular system, cilia movements and muscular contractions may be considered to serve in respiration.

In captivity the animals grow to a smaller size and the O_2 tension in them is less, though the O_2 content in the tanks is kept as high as in the sea water. The value of the O_2 tension of the body fluids of the medusa are not in conflict with the theories of gas diffusion in explaining respiration. There was no evidence of the secretion of O_2 within the body cavity. The body fluids indicate an O_2 -consuming property which though small is greater than that of sea water but not so large as that of the blood of the selachii. The conserving property of the animal is not due to presence of plankton but to the functions of the cells of the animal. This may be suppressed by KCN.

A. R. R.

12. FOODS.

W. D. BIGELOW, F. F. FITZGERALD.

"Sozolit." JON ALFRED MJOEN. *Tidskrift Kemi Farm. Terapi* 12, 349-59, 369-73(1915).—"Sozolit," a mixt. of salts, largely Na_2SO_3 and NaCl, is used as a preservative for meats. After an investigation and discussion of the question of preservatives for food materials, "Sozolit" in particular, M. urges that this preservative be permitted in Norway. He contends that it lends itself to control from the govt. chem. laboratories and recommends that when it is used it should conform to a minimum as well as a max. percentage in the foodstuff.

A. R. ROSE.

Caffeine content of Java tea. J. J. B. DEUSS. *Chem. Weekblad* 12, 938-43(1915).—D. favors the use of the refractometer for the detn. of caffeine in tea. The detn. of the amt. of caffeine can be used to judge the quality of tea. The minimum quantity of caffeine in good Java tea is 3%. The amt. of caffeine in tea bears no relation to the place where it is cultivated.

J. A. SAMUELS.

Casein from India. ANON. *J. Roy. Soc. Arts* 64, 69-70(1915).—Milk, in parts of India, especially in Baroda, cannot be distributed in a fresh condition, and is made into casein for export. One of the important uses for casein is in making galolith, a celluloid-like substance which is non-inflammable, and in tropical climates does not soften like rubber.

H. S. BAILEY.

Use of the "lactodensimeter." M. SIROT AND G. JORET. *Ann. fals.* 8, 123-4(1916).—With the "lactodensimeter" it is practicable to det. the d. of milk at 15°. The use of tables for calcg. the values obtained at higher temps. than 15° leads to errors.

H. S. BAILEY.

Nutritive value of boiled milk. A. L. DANIELS, *et al.* *Madison. Am. J. Dis. Children* 11, No. 1(1916); *J. Am. Med. Assoc.* 66, 220.—Rats fed on boiled milk grew about half their normal size and failed to reproduce. Boiling for 1 min. appears to render milk an inadequate food, the change taking place at about the boiling temp. Heating milk to 114° makes it even less valuable as a food. Care should be taken in the pasteurization process not to exceed the proper temp.

L. W. RIGGS.

The present status of the pasteurization of milk. S. HENRY AYERS. U. S. Dept. Agr., *Bull.* 342, 16 pp.(1915); cf. *C. A.* 9, 1353.—A discussion of the term pasteurization, its value, extent in the U. S., methods used, temp. and methods most suitable, operation and cost. A classification and diagram of bacteria in milk as affected by pasteurization is included.

E. H. INGERSOLL.

Fermented milks. L. A. ROGERS. U. S. Dept. Agr., *Bull.* 319, 30 pp.(1916).—A brief résumé of the present knowledge of fermented milks, embodying a discussion of the therapeutic value and various forms of fermented milk. A bibliography of the more important papers on the subject is included.

E. H. I.

The smoking temperatures of edible fats. KATHERINE BLUNT AND CLARA M. FRENEY. Univ. Chicago. *J. Home Economics* 7, 535-41(1915).—The smoking temp. of a fat is defined as the temp. at which it gives off visible fumes. This is found to be lower as the free fatty acid increases. Data are given for a number of fats and oils. An increase of 1.10% free oleic acid lowered the smoking point of neutral olive oil from 234 to 168°. The smoking point was found lower with increase of surface exposed. Finely divided foreign matter, as flour or animal charcoal, lowered the smoking point.

P. M. GIESY.

The determination of the origin of hydrogenated fats and the color reaction of Tortelli and Jaffe. J. PRESCHER. *Z. Nahr.-Genussm.* 30, 357-61(1915).—(1) Hydrogenated fish oils are present when the Tortelli-Jaffe reaction (*C. A.* 9, 1255) and either the Kreis-Roth test for arachidic acid or the cholesteryl acetate test are positive. (2) Simultaneous positive results of the Kreis-Roth and phytosteryl acetate tests may show rape oil as well as peanut oil. (3) Positive Soltsien and Baudouin tests prove the presence of sesame oil. A very low sapon. no. indicates rape oil. (4) Hydrogenated coconut and palm kernel oils can be detected by their high sapon. nos. (above 230) and by the Reichert-Meissl nos. and Polenske nos. which are peculiar to the crude oils. (5) In the detection of hydrogenated castor oil and cottonseed oil the hydroxyl no. of the former and the Becchi and the Hauchecorne reactions on the latter are of value. (6) The ratio of the I no. to n is not the same with hydrogenated fats as with animal fats. Coconut fat of a tallow-like nature is recognizable from other hydrogenated fats by its low I no. If other fats have a low I no. they must be tallow-like fats of unusually high m. p. (7) The Bellier reaction has only the most limited application to the detection of hydrogenated fats.

L. D. ELLIOTT.

The examination of honey by the precipitin method. HANS KREIS. Basel. *Mitt. lebensm. Hyg.* 6, 53-62(1915); through *Chem. Zentr.* 1915, II, 437.—The method of Thöni (*C. A.* 7, 3169) has been included in the Swiss "Lebensmittelbuch." K. has used the method on a large number of samples to det. the limits within which the ppt. can fluctuate for pure honey. After a discussion of the method and the results obtained by it, he concludes that the method, when carefully followed, gives reliable results, which, when considered with the results of analysis, clearly show whether the honey is adulterated, heated or spoiled. An examn. of 32 honeys gave values for the amt. of ppt. from 26.5 to 38.8 cu. mm., which agree very well with the results of Thöni.

H. E. WOODWARD.

The estimation of the color of flour and the detection (rendering visible) of bran particles in flour and grits. ORTO RAMMSTEDT. *Pharm. Zentralhalle* 56, 291-3(1915).—Official export type samples of wheat and rye flours are prepd. each year by the German Millers Assn. with the sanction of the Imperial Treasury Dept. These types are used for color comparison. Bran particles are rendered visible by staining the lignified portions with 1% alc. phloroglucinol soln. and concd. HCl, according to the method of Holz (*Apoth. Ztg.* 1892, No. 7).

C. O. EWING.

The identity of the proteins extracted from wheat flour by the usual solvent. C. H. BAILEY AND M. J. BLISH. Minnesota Agr. Expt. Sta. *J. Biol. Chem.* 23, 345-57(1915).—One% NaCl exts. from flour an amt. of gliadin equal to more than half the total protein in the ext. With 10% NaCl and 5% K_2SO_4 the exts. contain only approx. 15% of the protein as gliadin. The use of 5% K_2SO_4 is recommended for the detn. of the non-gluten proteins. Extn. with 50% alc. by vol. for 20 hrs. at room temp. yields an ext. containing a higher % of protein than when either 30 or 70% alc. is used. Complete sepn. of the gliadin occurs only when the extn. is made at 83-4°; this procedure is recommended. 93% of gliadin N (proportion of gliadin to non-gliadin N) is present in the exts. irrespective of the temp. of extn. (room temp. or 83°). The

amt. of non-gliadin proteins extd. by 50% alc. is const. regardless of the % of these constituents in the flour extd. The sepn. of gliadin from non-gliadin proteins by coagulation in H_2O at 100° is not quant. as considerable gliadin is not coagulated.

A. P. LOTHEROP.

Determination of corn meal in admixture with wheat flour. J. TRAMBICKS. *Chem. Ztg.* 39, 636(1915).—The ungelatinized starch of corn meal is much less sol. in malt ext. than that of wheat flour. 20 g. samples of meal of various compns. were digested with 200 cc. malt ext. and 200 cc. water for 2 hrs. at 65° and the solns. tested with a Zeiss refractometer, the reading for the malt ext. alone being subtracted from the total in each case. The refractometer reading for corn meal was 9.6, for wheat flour 16.6. Mixts. containing 50, 60, 70, 80 and 90% corn meal gave the following readings, resp.: 13.6, 12.9, 12.8, 11.9, 9.5.

E. H.

The determination of the alcohol extract in meat extracts. A. HEIDUSCHKA. München. *Z. öffent. Chem.* 21, 120-1(1915).—There is a misprint in the "Vereinbarungen zur einheitlichen Untersuchung und Beurteilung von Nahrungs und Genussmitteln usw. für das deutsche Reich," vol. 1, p. 50, in Liebig's method for detg. alc. ext. in beef ext. The corrected sentence should read: "2 grams of ext. is weighed into a beaker, dissolved in 9 cc. (not 90 cc.) of water, and treated with 50 cc. of 93% alc."

H. E. WOODWARD.

Harmful effects of beet fodder upon milk. J. ROLLE. *Z. Nahr.-Genussm.* 30, 361-2(1915).—The betaine in beet roots produces a bitter taste in milk. Betaine, by uniting with the lactic acid formed, retards the souring of the milk for some time. Such a milk can be used only for cheese making.

L. D. ELLIOTT.

The composition of some foods from Bulgaria. D. WESSOW AND M. NIKOLOW. *Z. Nahr.-Genussm.* 30, 362-74(1915).—Tables of analyses of hog fat, butter, honey, beeswax, and especially wines.

L. D. ELLIOTT.

The mineral matter content of the food-rations for working horses. W. VÖLTZ. *Z. Spiritusind.* 38, 177-8(1915).—V. shows that the oat substitutes sometimes are very low in mineral matter; the lacking salts are to be added to such feed.

L. W. H.

Biochemical comparison between mature beef and immature veal. WM. N. BERG. *Bur. Animal Ind. J. Agr. Research* 5, 667-711(1916).—No physiologically significant differences in chem. compn. between mature beef and immature veal (from calves 7 days old or younger) were detected. In a large number of artificial-digestion expts. immature veal digested as fast as mature beef. Cats were fed on a diet in which immature veal was the sole source of N. The young animals grew normally on the diet; the older ones became fat. A pair of cats, after living $\frac{1}{2}$ of a year on the diet, produced a litter of healthy kittens which, after the nursing period, continued on the immature veal diet with excellent growth. The work indicates that immature veal, when properly prepared, is fit for human food, especially when its deficiencies in fat and possibly in small amts. of undetd. constituents are counterbalanced in the ordinary mixed diet. A bibliography is appended.

W. H. FRY.

Detection of horse flesh in preserved sausage by means of the biochemical precipitation method. C. DUMITRESCU AND A. MANULESCU. *Buletinul Chimie* 17, 61-7; *Chem. Zentr.* 1915, II, 761-2.—For the prepn. of the precipitating serum of seroprecipitins, rabbits are injected subcutaneously at intervals of 5 days with increasing amts. (5, 10, 20, 40, 60, 80 cc.) of horse serum. After the third injection the activity of the rabbit serum is tested and the injections continued until a minimum of 1 in 10,000 is reached when the serum is obtained in the usual manner and preserved in ampules of 1.25 cc. in a cool place of even temp. The seroprecipitin keeps its strength about 4 months after which it slowly loses its activity. In applying the test, the skin

and 1-2 mm. of the outer layer are removed from about 20 g. of the sausage to be tested and the remainder, freed as much as possible from fat, is ground fine, mixed with 9% physiologic serum to a thick broth in an Erlenmeyer flask and allowed to stand in ice 50 hrs. with occasional stirring. The liquid is then pressed out, centrifuged and the fat layer removed from the clear serum. To each of 2.5 and 5 cc. portions of this serum are added 25 cc. physiologic serum, the mixts. centrifuged until perfectly clear and set aside for comparative material in case of failure. To 4 uniform 12 cm. test tubes is added as follows: Nos. 1 and 2, about 1 cc. of the undiluted serum as obtained above from the sausage containing horse flesh, to No. 3 1 drop of horse serum and 1 cc. physiologic serum and to No. 4 1 cc. of a serum from a sausage free of horse flesh. To each of the tubes 1, 3 and 4 is added 0.1 cc. of seroprecipitin and to 2, 0.1 cc. of the serum of an untreated rabbit. In tubes 1 and 3 after agitation a cloudiness appears which increases in course of 30 min. to a ppt. Tubes 2 and 4 remain clear. This test detects 2% of horse flesh with a seroprecipitin of 1 in 18,000 activity. A seroprecipitin of 1 in 1000 activity gives almost no reaction with sausage containing 2-3% of horse flesh. Clean work is essential to success.

L. W. RIGGS.

The use of the blood of the stock-yard animals as food. E. SALKOWSKI. Univ. Berlin. *Berl. klin. Wochschr.* 52, 597-9(1915).—The use of the blood of the stock-yard animals for food is advocated. Three ways of preserving it are suggested: (1) with antiseptics, as CHCl_3 , formalin, salicylic acid, boric acid, etc.; (2) with a large amt. of sugar; (3) by drying and pulverizing it.

JULIAN H. LEWIS.

Homogenizing milk. N. J. NIELSEN. U. S., 1,168,823, Jan. 18. Milk is passed rapidly through 2 systems of piping in the first of which a much higher temp. and pressure are maintained than in the second, so that the fat globules are burst and the product sterilized.

Pasteurizing bottled milk. L. J. CRECELIOUS. U. S., 1,168,789, Jan. 18.

Pasteurizing liquids containing gas. E. KRAFFT. Ger., 285,488, Feb. 27, 1912.

Solid fruit conserves in stick form. H. KOCH. Ger., 285,727, Jan. 30, 1914. Hot liquid fruit mass is poured into molds wherein it solidifies and shrinks upon the application of cold H_2O to the forms, thereby permitting ready removal. As a further result of the shrinking a combination of the gelatinous matter and the H_2O takes place in such manner that a light-colored, interiorly moist and exteriorly smooth solid product is obtained, which upon soln. in a little H_2O yields the usual readily spreading jelly.

Food preparation. F. J. HOWITT. Brit., 19,803, Sept. 15, 1914. A food prepn. is made by baking a dough of ground maize, ground peanut cake containing 20-25% of oil, flour, and preferably sugar, salt, etc. The maize may be ground with or without the cob, and in the latter case the bran and germ may be removed. The prepn. may be in the form of biscuits or meal, and may be given to dogs, etc.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Analysis of drinking water. WILLIAM A. PEARSON. Hahnemann Medical College, Phila. *Hahnemannian Monthly* 51, 19-21(1916).—Bacteriologic analysis does not reveal the dangerous character of a drinking water. Evidences of contamination are best detd. by estn. of the products of protein decompn.

JOSEPH S. HEPBURN.

Report on water. W. W. SKINNER. *J. Assoc. Official Agr. Chemists* 1, 458-61 (1915); cf. *C. A.* 7, 524; 9, 3310.—As a result of a study of the method for sepg. Ca and Sr, it is suggested that the method be modified by substituting a 1% soln. of $(\text{CO}_3\text{NH}_4)_2$

for the cold water prescribed for washing the mixed oxalates, and that at least 2 extns. of the mixed nitrates with the ether-alc. solvent be made. E. BARTOW.

The disinfection of water in war-times. H. KUEHL. *Deut. Vierteljahr. offenl. Gesundh. Pflege* 47, 38(1915); *Wasser u. Abwasser* 10, 65-6(1915).—K. discusses the purification of water by filtration, boiling, chemical pptn., disinfection, ozonization and ultraviolet-ray treatment. Boiling constitutes an abs. safeguard. The portable field app. provides for subsequent aeration to do away with the stale taste. The Berkefeld and Hansa filters are likely to diminish in efficiency as time goes on. The candles either have to be exchanged or brushed at certain intervals. K. does not consider Cl disinfection as particularly suited. For ozonization the water must first be clarified. Ultraviolet-ray treatment is too expensive. Not every supply is adapted to it. ARTHUR LEDERER.

Influence of weather conditions on amounts of nitric acid and of nitrous acid in the rainfall near Melbourne, Australia. V. G. ANDERSON. *Report Brit. Assoc.* 1914, 338-9; *Quart. J. Roy. Met. Soc.* 41, 99-122(1915).—The results of analyses of rain-water collected at Canterbury, near Melbourne, under different conditions of weather, showed that the amts. of nitrates and nitrites in the rain are very much greater with tropical than with antarctic types. With antarctic types of weather the amts. of N were from 0.002 to 0.005 kg. per hectare. Of tropical rains, the spring and autumn types gave 0.018 kg., the summer type 0.027 kg. and the heat-wave type 0.039 kg. per hectare. Intermediate results were obtained in antarctic depressions, with more or less tropical influence, and in tropical depressions with antarctic influence. E. J. C.

New spring in Fiuggi. G. AMPOLA AND G. LIBERI. *Ann. chim. applicata* 4, 205-30(1915).—The H_2O is very limpid, perfectly neutral, and remains clear in the test glasses, without giving the least opalescence; it is perfectly colorless, odorless, and without taste. The number of colonies of bacteria counted in clear cultures in gelatin, kept at 20° for 7 days, and in cultures of albumose agar, kept at 20° for 15 days, were, per cc. of H_2O : liquefying *Schisomyces*, 7; non-liquefying *Schisomyces*, 31; *Hyphomyces*, 14; suspected pathogenic colonies, none. The temp. of the H_2O was quite const. oscillating between 11.5 and 12°. The sp. gr. was within 1.0002. The f. p., compared to that of the purest distd. H_2O , was a few hundredths of a degree lower. The sp. elec. cond. K_{18} was 80.2×10^{-8} . Measurements of radioactivity were made. They were calcd. for the H_2O at the spring. The av. current of satn. per l. was 4690×10^{-8} abs. electrostatic units, or 1894.7×10^{-18} amp.; the av. emanation per l. was 2131.1×10^{-12} Curie units or 1278.7×10^{-12} cu. mm. The radioactivity is due solely to Ra emanation dissolved in the H_2O , and not to the presence of solid radioactive substances. The activity diminishes with lapse of time, is also lost on boiling the H_2O , and was not acquired again after keeping the boiled H_2O a month in a closed bottle. The residue from the evapn. of 100 l. of the H_2O was perfectly inactive. No liberation of gas was noted in the H_2O at the spring, nor on standing. Using Reichardt's and Frankland's methods, it was found that the H_2O contained the following dissolved gases per l.: 36.80 cc. CO_2 , 3.71 cc. O, 15.90 cc. N. In 100 l. of the H_2O there were found present (all wts. in g.): total CO_2 , 10.36; combined CO_2 , 0.8323; semi-combined CO_2 , 0.8323; free CO_2 , 8.6954; Na, 0.4427; K, 0.1327; Li, 0.00001; Ca, 0.6327; Sr, 0.0112; Mg, 0.1914; Fe, 0.0238; Al, 0.0248; Cu, 0.0005; Mn, 0.00002; Cl, 0.8688; SO_4 , 0.4822; NO_3 , 0.0865; PO_4 , 0.0019; CO_3 , 1.1349; TiO_2 , 0.0036; V_2O_5 , 0.0010; SiO_2 , 1.0740; total fixed residue at 180°, 5.1500. The residue is free of alk. carbonates. The authors believe the H_2O to be excellent for table use, on account of its distinctly saline character, its very slight mineralization, its strong radioactivity, the traces of Li it contains, and the relatively large amts. of Sr present. In an appendix a comparison is made of this H_2O with the H_2O of the well-known and old "Fiuggi Spring." The slight differences between

the 2 are probably due to the variation of the last layers traversed by the waters.
S. LEVY.

Public water supplies. PERCY GRIFFITH. *Surveyor* 48, 331-2, 371-4(1915).—A lecture discussing sources, reservoirs, and pumping machinery. For a gravity system in England storage capacity should be provided for from 120 to 250 days. Loss by evapn. may amount to 12 to 27 in. per year over the whole water-shed. W. D. C.

Slate beds. ANON. *Surveyor* 48, 411(1915).—Quotations from a pamphlet issued by the Slate Bed Biological Sewage Disposal Co., Limited. At Devizes about 680 tons of pressed sludge were produced in a year when chem. pptn. was used while from slate beds only 50 tons of inoffensive mold were obtained during a similar period.
W. D. C.

London's water supply. ANON. *Surveyor* 48, 307(1915).—According to the twelfth annual report of the Metropolitan Water Board the av. daily supply for the district in 1914-15 was 36.08 gallons per capita. Of the daily av. of 245 million gallons the Thames furnished 58.5, the Lee 23.1, and springs and wells 18.4%. W. D. C.

The water supply of Copenhagen. SVERRE MALM. *Intern. Z. Wasserversorg.* 1915, 1-3, 9-11, 24-5; *Wasser u. Abwasser* 10, 74-5(1915).—Since 1893 ground water has been used exclusively. Part of it contains Fe which must be removed by aeration and filtration. The plant at Lake Soender consists of 74 wells, 50 m. and 30 m. deep, which furnish a max. of 30,000 cu. m. per day. The plant in the Harestrup-brook valley also furnishes approx. 30,000 cu. m. per day. The 2 supplies are combined and aerated. The supply from the Veil-brook valley furnishes approx. 33,000 cu. m. per day. The first 2 supplies mentioned are filtered and the Fe is removed. The water consumption in Copenhagen during the fiscal year of 1912-13 amounted to 124 l. per capita.
ARTHUR LEDERER.

The water supply of Berlin. EGGERT. *Wasser u. Gas* 5, 158-60(1915); *Wasser u. Abwasser* 10, 76(1915).—E. discusses the development and present status of the water supply. The enlarged plants will furnish 480,000 cu. m. per day. Up to the present time the total cost of all works is about 124 million marks.
ARTHUR LEDERER.

Brief notes of experiments in sewage purification by forced aeration. J. P. WAKEFORD. *Surveyor* 48, 132-3(1915); cf. *C. A.* 9, 2785.—At Wakefield expts. were carried on in a tank 30 ft. by 12 ft. by 6.5 ft., with $\frac{1}{2}$ hr. for filling, 2 hrs. for blowing, 2 hrs. settling, and $\frac{1}{2}$ hr. for emptying. Results were satisfactory, but several engineering difficulties must be overcome before the process can be worked on a large scale. When this is done it is safe to assume that the treatment will be less offensive, more rapid, will require less filter area, and be less expensive to maintain than present processes on account of the omission of chemicals, greater fertilizing value of the sludge, and less expense for attendance.
W. D. COLLINS.

The sludge problem. Standards for effluents recommended by the Royal Commission on Sewage Disposal, and sewage purification by aeration in presence of activated sludge. H. M. WILSON. *Surveyor* 48, 74-6(1915).—Attention is called to various processes which successfully deal with sludge, though little is known as to the economy of them. W. believes that in recommending standards for effluents the Commission decided against the weight of evidence placed before them and made a mistake. A short account of the development of the activated sludge method and the results of its use leads to the conclusion that the process produces satisfactory purification, but the cost of operation has not yet been fully worked out.
W. D. COLLINS.

Non-septic house and town sewage drainage and sewage-drainage ventilation systems. ISAAC SHONE. *Surveyor* 48, 80-3(1915).—Illustrated description of ventilatic flushing system.
W. D. C.

Sewage works operation and analytical methods. SANITARY ENGINEERING SECTION OF AM. PUBLIC HEALTH ASSOC. *Surveyor* 48, 322-3(1915).—Committee report. W. D. C.

Treatment of sewage by aeration in the presence of activated sludge. E. BARTOW. *Met. Chem. Eng.* 13, 901-4(1915); cf. *C. A.* 9, 1521.—Description of the status of the activated sludge process of sewage treatment in America, with details of the work done at the Illinois State Water Survey. F. W. MOHLMAN.

The oxidation of sewage without the aid of filters. III. E. ARDERN AND W. T. LOCKETT. *Surveyor* 48, 450-4(1915); see *C. A.* 10, 502. W. D. COLLINS.

The destructive distillation of feces. J. MENZIES. *Surveyor* 48, 498-501(1915).—The av. results from laboratory distn. of 48 samples of press cake from sewage sludge gave per ton, oil 9 gallons, NH_3 (as $(\text{NH}_4)_2\text{SO}_4$) 60 lbs., "spirit" 0.75 gal., gas 5,500 cu. ft., residue 750 lbs. The av. from 12 samples of crude feces was, oil 16 gallons, NH_3 (as $(\text{NH}_4)_2\text{SO}_4$) 88 lbs., gas 3200 cu. ft., residue 240 lbs. per ton. Sewage sludge is so poor a conductor of heat that for successful distn. it must be dried before feeding to the retort. Caking must be prevented either by mixing with inert material or by some appliance in the retort. A description, with drawing, is given of a destructor which will take care of feces from about 2,000 men. The material is fed to the top plate of a series of five, one above the other inside a gas-tight box 6 ft. by 4 ft. by 5 ft. high. The plates are hollow and heated by gas from a producer, which also provides the necessary power by means of a gas engine. Rakes stir the material and gradually carry it down from one plate to another till at the bottom the carbonaceous residue is removed. The NH_3 liquor recovered contains pyridine bases and when it is sprinkled over feces no flies will approach the material. The NH_3 liquor has been tested as a protection against Cl gas. A spray of NH_3 in front of a trench united with Cl gas liberated at 25 lbs. pressure from a perforated pipe 15 ft. from the trench. No discomfort was experienced by men in the trench. W. D. COLLINS.

The destructive distillation of sewage. ANON. *Chem. Trade J.* 57, 453(1915); cf. preceding abstract.—Notes on an app. described by J. Menzies before Inst. Sanit. Engrs. in Nov., 1915. A thin layer of feces constantly agitated on hot plates in a still undergoes rapid destructive distn., yielding useful distillates without nuisance. The oil contains less than $\frac{1}{4}\%$ S and is good for fuel. The first fraction from oil is colorless spirit of 0.760 sp. gr., the 2nd fraction a pale, burning oil and the last fraction is an excellent lubricant with good viscosity. NH_3 is recovered as 6 oz. liquor. R. B. D.

Sewage works for military camp. ARTHUR W. SMITH. *Eng. Record* 73, 82-3 (1916); *Surveyor* 48, 516-7(1915).—The plant built at Ripon, England, to treat the sewage of an army corps of 42,000 men with 10,000 horses consists of 2 screening tanks, 4 Dortmund tanks and 4 long subsidence tanks, percolating bacteria bed, 10,000 sq. yd. in area, 6 ft. deep, having slag and gravel as filter media. The effluent from the filters is settled in Dortmund tanks and then discharged into the River Ure. The total tank capacity is 500,000 imp. gal. per day. FRANK BACHMANN.

Sewage gas tank utilized for light and heat. CHARLES C. HOMMON. *Eng. Record* 73, 182-3(1916).—The vents of the Imhoff tanks at the Peachtree sewage treatment plant at Atlanta, Ga., were capped and sufficient gas collected for the use of the laboratory and for domestic needs. About 30,000 cu. ft. of gas per day is available from the decompn. of the sludge in the tanks. Photographs accompany the article showing the collectors over gas vents of the tanks and a gas holder of 1400 cu. ft. capacity. F. B.

Sanitary progress in Peru and Bolivia. H. J. BINGHAM POWELL. *J. Roy. Sanitary Inst.; Surveyor* 48, 412-4(1915).—P. describes waterworks and sewage installations in several cities and towns. Most of the water supplies of Peru are from wells in gravel.

Some Bolivian supplies are from storage reservoirs. In Peruvian coast cities there is practically no rainfall so provision is made only for domestic sewage. In Bolivia, sewer capacity is provided for precipitation at the rate of $\frac{3}{4}$ in. to 1 in. per hour with $\frac{1}{2}$ to $\frac{1}{3}$ of this reaching the sewers. At present, refuse of towns in Peru is conveyed by carts to tip-heaps, some of which are as old as the towns, 300 to 400 years, so that all org. matter in the bottom layers has been decomposed. W. D. COLLINS.

The soot- and dust-fall of English towns and cities. J. B. C. KERSHAW. *Chem. Trade J.* 57, 363-4(1915).—A summary of serial detns. made by a committee for the investigation of atm. pollution, monthly reports of which have been published in the *Lancet* (London). A cast-iron funnel enameled on the inside and having a collecting area of 4 sq. ft. is protected from birds by a wire guard, and is drained into bottles. Rain washes soot and dust into bottles. The collected rain water is tested for insol. matter, tar, carbonaceous matter, ash, dissolved matter, combustible ash, chloride, sulfate, ammonia. The dust-fall in a year averaged in tons per sq. mi. per month at Oldham, 79.79; Ancoats, Manchester, 71.39; Technical School, Manchester, 45.08; Birmingham, 59.46; Sheffield, 55.55; Liverpool, 47.89; Embankment Gardens, London, 49.84; Golden Lane, London, 32.89; York, 23.14; Malvern, 5.45. R. B. DOLG.

Choice of alloys for water work design (CARPENTER) 9.

Disinfectant. M. ENSELMANN and B. MERKEL. U. S., 1,167,642, Jan. 11. A stable, whitish powder, sol. in H_2O and insol. in alc. and ether, is made by grinding together NaOH with about twice its wt. of mercurichlorophenyl sulfate, mercuriphenyl acetate, mercuribenzoic acid, mercurichlorobenzoic acid or mercurized *p*-nitrophenol. All these products are sol. in dil. alk. solns.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Soil colloids. O. REITMAIR. *Wiener Landw. Ztg.* 65, 455-8(1915).—A descriptive article pointing out the importance and the nature of the action of colloids in the soil. C. F. MILLER.

A comparison of methods for the determination of soil phosphorus. W. O. ROBINSON. *Bur. Soils. J. Ind. Eng. Chem.* 8, 148-51(1916).—The fusion methods of Washington and of Fischer give accurate results. V interferes with the P detns. in soils. This influence can be avoided by reducing the V with $FeSO_4$ and pptg. at low temps. with shaking. With soil solns. it is not necessary to add H_2SO_4 to prevent the reoxidation of the vanadyl salt. The influence of V is also avoided by using the gravimetric method, provided precautions are taken for complete pptn. and the NH_4MgPO_4 ppt. is not allowed to stand too long. W and Ti do not interfere with the detn., by the gravimetric method, provided precautions are taken to make the pptn. complete. The compn. of the feathery ppt. is dependent on the nature of the bases in the soln. before pptn. Proper pptn. and washing of the yellow ppt. prevents the formation of the feathery ppt. or reduces it to a negligible amt. W. H. FRY.

Nitrification and total nitrogen as affected by crops, fertilizers, and copper sulfate. C. A. JENSEN. *J. Am. Soc. Agron.* 8, 10-22(1916).—This paper deals with a study of changes in nitrification and total N under field conditions at Rocky Ford, Colo., during the summers of 1911 and 1912. The object of the NO_3 detns. was to find some method of counteracting the detrimental effect of excessive NO_3 accumulations which

gave promise of becoming a serious factor in beet culture on certain soils in Colo. In 1911 mustard had some effect in checking the accumulation of NO_3 in the field. CuSO_4 at rate of 100 lbs. per acre on fallow land reduced the av. accumulation to 60% of the amt. found in the check. Molasses decreased and manure slightly increased nitrification. Waste Ca from the beet factory strongly increased nitrification. Active nitrification began about June 1st, reached its max. about July 15th, and ceased after Aug. 15th. The mustard plot contained less total N than any other plot. The fallow plots treated with CuSO_4 and molasses contained less total N than their checks. In the cases of the Ca and manure fallow plots less total N was found than in the checks. The reverse was true in regard to NO_3 . Nitrification in 1912 was less than in 1911. In 1912 nitrification was decreased by general fertilizing materials. There was not much change in nitrification during the summer season. J. J. SKINNER.

The displacement by water of the nitrogenous and mineral material contained in leaves. G. ANDRÉ. *Bull. soc. chim.* 17, 429-41(1915).—A. endeavored to find the amts. of certain of their constituents that leaves lost while lying on the ground during the winter. The rains, aided by insects and bacteria, make available the N from the proteins, the P from mineral and org. P compds. and the K from salts of org. acids. On Oct. 17, 100 leaves of the chestnut tree were analyzed and on the following 21st of Apr., a second hundred, which had wintered on the ground, were analyzed and a loss of 7.5% N, 67.4% P (calcd. as H_3PO_4), and 87.7% K was found. Dead leaves after wintering in piles on the ground contain about twice as much N and the same amt. of H_3PO_4 as a good farm manure but the K is almost entirely lacking. This N does not, however, nitrify as readily as that in the manures. To find the influence of H_2O alone, a known wt. of leaves was covered with H_2O and a few drops of formalin added and after a certain period of time the solns. were decanted off, replaced by more H_2O and the solns. analyzed. The last portion (extd. 255 days) contained 6.27% of the total amt. N, 74.14% of the total H_3PO_4 and 94.58% of the K_2O . The N evidently exists in the leaf as a protein which does not readily hydrolyze. It was observed that the younger the leaf, the larger % of N, PO_4 , and K was extd. in the first week. The same expts. were carried out with respect to the SO_3 , CaO and MgO content. After 1 month's immersion in H_2O , 56.8% of the total S, 50.72% of the MgO but only 20.03% CaO had passed out. R. L. SIBLEY.

Sampling device (SHAW) 1.

Fertilizer from molasses refuse. E. HERZKA. U. S., 1,168,255, Jan. 11. Dry fertilizer is prepd. by evapg. molasses refuse *in vacuo* to 44° B $\acute{\text{e}}$., adding about 30-50% its wt. of mineral phosphate, guano or bone meal to the concd. material and treating the mixt. with sufficient concd. H_2SO_4 to react with the phosphate added and also to decompose the K_2CO_3 of the concd. molasses refuse and form K_2SO_4 .

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Spanish apple-wine. WARCOLLIER. *Ann. fals.* 8, 27-33(1915).—A description of the Spanish methods of making apple-wine, followed by a tabulation of the analyses of 9 samples. The % of EtOH varies from 3.8% to 9.1%, reducing sugars from 21.5 to 75.4 g. per l., total acid as H_2SO_4 from 1.8 to 3.9 g. per l., and volatile acids as H_2SO_4 from 0.9 to 2.51 g. per l. The amt. of apple-wine exported in 1910 from Spain to various countries is given. H. S. BAILEY.

Influence of sulfurous acid upon the fermentation processes due to yeasts and bacteria in wine, perry and cider. H. MÜLLER-THURGAU AND A. OSTERWALDER. *Landw. Jahrb. Schweiz.* 28, 480-528(1914); *Bull. Agr. Intelligence* 7, 977-80(1915).—The action of SO_2 upon wine, perry and cider was investigated by introducing it in the form of $\text{K}_2\text{S}_2\text{O}_5$ into the juice of grapes, pears and apples. After 1 hr. (or longer) the amt. of free and fixed SO_2 was detd. (by titration with 0.02 N I soln.). The increased fixing power for SO_2 shown by the juices of over-ripe pears and apples and of grapes infected by *Botrytis*, probably depends upon the amt. of AcH they contain. The juice from normally ripe fruit is free from aldehyde and fixes SO_2 to a far less extent, forming an unstable compd. with dextrose. Whatever the state of maturity of the fruit, free SO_2 is always found in the juice after treatment, and this undergoes oxidation during the storage period before fermentation. The compd. of SO_2 and dextrose also undergoes decompn. during this period. During fermentation the SO_2 -AcH compd. remains unchanged, but the SO_2 -dextrose compd. is decompd. with the liberation of free SO_2 , which, however, becomes fixed very quickly, and is subsequently oxidized to SO_3 . AcH produced as an intermediate product and the aldehyde originally present in the juice, undergo reduction to EtOH during fermentation, hence most of the SO_2 added remains in the free state, but as the production of aldehyde increases it gradually becomes fixed. As fermentation proceeds, the free SO_2 is oxidized by the atm. O to SO_3 , but some may be fixed by the AcH produced by oxidation of the EtOH. Only free SO_2 has a retarding or inhibiting action upon fermentation. The resisting power of yeasts to SO_2 differs with different varieties. The inhibition of alc. fermentation is dependent upon the kind of juice, the initial yeast flora, and probably also upon the oxidase content. The effect of SO_2 is greater if it be added to the fresh grape juice than if introduced after fermentation has set in; with the juice of "sleepy" pears the reverse holds good, owing to the acid combining with aldehyde. The decompn. of malic acid in wines by *Bacterium gracile* is prevented by smaller amts. of free SO_2 than are necessary to inhibit alc. fermentation. To prevent such decompn., SO_2 should be added before fermentation. Small amounts of free SO_2 will prevent a wine from tasting of lactic acid. Perry rich in aldehydes will require more, but an undue excess should be avoided, as the sensitive lactic bacteria would be adversely affected.

L. W. HAAS.

Carboxylase. ARMINIUS BAU. *Wochschr. Brau.* 32, 405-6(1915); cf. C. A. 9, 2284.—B. studied the action of dried yeast on free CH_3COCOOH in the presence of K_2HPO_4 , Na_2HAsO_3 and H_3BO_3 , respectively, as "puffer." Expts. with beer in all its stages of manufacture (from pitched wort to the finished product) did not furnish any indication of the presence of carboxylase; this experience confirms C. Neuberg's statement that from living yeast no carboxylase diffuses into the surrounding liquid.

L. W. HAAS.

Changes in the physiological conditions of brewery yeasts. O. FÜRNROER. *Z. ges. Brauw.* 38, 297-9, 305-7, 313-6, 345-7, 353-5, 361-4(1915).—The detn. of the fermentative energy serves as a convenient means of information as to the enzymic and physiological condition of yeast. F. examined continuous yeast propagations of different types of yeast for a considerable period to show the gradual degeneration of practice yeast, if no measures are taken against it, and investigated the regeneration of degenerated yeast by means of different yeast stimulants. The yeasts were washed with tap-water and distd. water without and with the addition of asparagine, glycerol, tartaric acid, CaSO_4 , MgSO_4 , KH_2PO_4 , K_2HPO_4 , K_3PO_4 , Na_2HPO_4 , MgCO_3 , CaC_2 , CaCl_2 , MgCl_2 , NaCl , KI and H_2SO_4 (soaked for 1 hr. and subsequently neutralized with NaOH or Ca(OH)_2), resp. After this treatment the fermentative power was detd. for all compounds tried, CaSO_4 effected the highest increase in fermentative

power. The tap-water was much superior to distd. water in this respect. The above facts explain the comparatively rapid degeneration of yeast in breweries using soft water. To guard against this trouble, it is best to use the pitching yeast from brew to brew unwashed or to wash it with water to which CaSO_4 has been added. In another series of expts. the stimulants were directly mixed with the pressed out yeast (0.4 to 1.0 g. per 5 g. pressed yeast) and then the fermentative power detd. CaSO_4 again produced the best results. Some of the salts showed a reverse effect to that observed when employed in dil. soln. for washing; especially detrimental were H_2SO_4 and H_3PO_4 and even K_2PO_4 (which, dissolved in the wash water, produced a beneficial effect). The differences in the stimulating power of different stimulants disappeared nearly entirely when they were dissolved in the same wort; furthermore, their effect was practically negligible for all stimulants tried with the exception of MgCO_3 , which distinctly depressed the fermentative power. These results have some practical significance, as they show that an addition of CaSO_4 to the mashing water for the purpose of stimulating the yeast is unnecessary. The effect of stimulants on the physical and chemical properties of yeast was also studied. All expts. led to the conclusion that CaSO_4 is not only a cheap, but also the best, and when not properly applied, the least harmful among all yeast stimulants.

L. W. HAAS.

Yeast and attenuation. M. H. DALY. *Brewers' J.* 51, 508(1915).—The different factors influencing attenuation are briefly reviewed.

L. W. HAAS.

Some facts concerning yeast. TH. BOKORNY. *Allgem. Brau.-Hopfen-Ztg.* 55, 1653-4(1915).—B. reports on expts. on hydrolysis of yeast protein by means of H_2SO_4 (N and $0.1 N$) and by NH_4OH (N and $0.1 N$) and on the proteolysis by yeast (in the presence of H_3PO_4 , H_2SO_4 and organic acids, resp.) of different animal and vegetable protein material (pea flour, soy-bean flour, rape-seed flour and meat meal).

L. W. HAAS.

Yeast fat. TH. BOKORNY. *Allgem. Brau.-Hopfen-Ztg.* 55, 1803-5(1915).—The more important investigations on the quantity and nature of fat in yeast, and the factors influencing both are reviewed and the feasibility of the technical production of fat from yeast is discussed. B. points out that the fat content of yeast can only be increased to a commercially feasible height by plentifully administering carbohydrates and protein to the growing yeast. The conditions for increasing abnormally the fat content of yeast are not fully known. Extensive study of "fat-yeast" (fat-producing yeast) is still required, if to the advocates of its commercial employment not more is known than that published in the literature.

L. W. HAAS.

Diastase preparations and their application in practice. I. POLLAK. *Brau.-Malzind.* 17, 14-7(1916); cf. *C. A.* 9, 2568, 2570, 3116, 3326.—Review.

L. W. H.

Gluten turbidity. F. EMSLANDER. *Wochschr. Brau.* 33, 20(1916).—The designation "gluten" for the substance causing the well-known turbidity of beer on cooling is incorrect, as this substance is not identical with the animal gluten (or gelatin), both behaving differently to yeast endotryptase. It is also incorrect to call above turbidity "gluten turbidity." E. proposes to call it most correctly "protein turbidity."

L. W. HAAS.

Potato starch as malt adjunct in the production of beer and its working in practice. E. JALOWETZ. *Brau.-Malzind.* 17, 2-5(1916).—Potato starch is a suitable malt adjunct and may be employed in proportions up to 20%, depending upon the condition of the malt used.

L. W. HAAS.

Determination of moisture in bitter principles in hops. Ö. WINGER. *Wochschr. Brau.* 33, 11-2(1916).—Another reply to D. Wiegman's criticism of W.'s work on above subject (cf. *C. A.* 10, 248).

L. W. HAAS.

Working of sugar beets in Austro-Hungarian distilleries. A. P. KOŁOCZEK. *Z. Spiritalind.* 38, 9-10(1915).—The following points are briefly discussed: (1) Prevention of fermenting over by addition of oil, (2) steaming of beets, (3) prepn. of yeast, (4) conducting of fermentation, (5) procedure in working sugar beets and potatoes simultaneously, (6) degree of fermentation, (7) distn., (8) nutritive value of beet-slop, and (9) mode of delivering slop to cattle.

L. W. HAAS.

Sucrose as adjunct to malt and its inversion during the brewing process. F. SCHONFELD AND H. KRUMHAAR. *Wochschr. Brau.* 33, 9-11(1916).—The suitability of sucrose in the production of beer is discussed and the changes in the brewing process involved by its use are indicated. Expts. on the inverting action on sucrose of the brewing processes led to the following conclusions: Boiling for 1 hr. of wort contg. cane sugar does not effect inversion of the latter. During pasteurization a more or less complete inversion takes place according to duration of pasteurization. In resting beer sucrose usually disappears within a short time, whether it be added before or after principal fermentation. In beers pasteurized shortly after the addition of sucrose, the latter may be met in considerable quantities.

L. W. HAAS.

Barleys of crop 1915. R. HEUSS. *Z. ges. Brau.* 38, 411-3(1915); cf. C. A. 10, 660.—The extreme values are given of the analyses of barleys so far published by the different investigators and the results are briefly discussed.

L. W. HAAS.

Regeneration of pitch. R. HEUSS. *Z. ges. Brau.* 38, 413-4(1915).—Waste pitch is heated in a kettle to about 200°, and this temp. maintained until spattering and foaming have ceased. The foam and impurities on the surface of the molten mass are then removed by a large ladle, 10% paraffin added, well mixed and then allowed to settle for some time, after which the liquid pitch is poured through a fine meshed sieve into suitable receptacles (pitch boxes). Thus regenerated, "old pitch" was found a suitable adjunct to fresh pitch in proportions up to 50%, provided that the regenerated pitch originally was a good grade product.

L. W. HAAS.

Effect of disinfectants on pitch. R. HEUSS. *Z. ges. Brau.* 39, 1-3, 9-11(1916).—As typical specimens a rosin oil pitch (A) and a paraffin pitch (B), further "regenerate" (R), "mammut" (M), A + 10% R and A + 10% M were exposed to the action of 2% CH₃O, 5% antiformin, 5% montanin, 5% technical NH₄F.HF., 1% HF and 3% pyricite, resp. Oak-wood blocks coated with above pitches or mixts. were partially immersed in the solns. of the disinfectants and the effect noted from time to time. Antiformin attacked all coats so strongly that they usually were completely destroyed after 2-3 hrs. exposure; a very slight action within 24 hrs. was noticed with HF on A, B and A + 10% R. All other disinfectants, though frequently renewed, did not produce the slightest effect within 24 hrs. on any of the pitches. The effect of sulfuring on pitch also was investigated. Dry S vapors did not produce any perceptible effect, while in the presence of moisture bluish white depositions of S were noticed at the damper spots after 24 hours. The resistance of pitching mixts. to the disinfectants commonly employed in the brewery (with the exception of antiformin and HF) suggests sterilizing of trade packages by disinfectants and dispensing with repitching after each use. Expts. in this direction proved entirely successful, provided the coat of pitch was not injured and the disinfectant was applied in the proper way. The best results were obtained with Röder's "automatic barrel cleaning and disinfecting app. with adjustable atomizer."

Pharmacopeial standards for whiskey and brandy (BERINGER) 17. Composition of some Bulgarian wines (WESSOW) 12.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Two hydrastinines of commerce. EDUARDO FILIPPI. Univ. Camerino. *Arch. farm. sper.* 20, 371-91(1915).—No appreciable difference was found between hydrastinine procured from Bayer and that procured from Merck. A. W. DOX.

Note on the melting point of salicylic acid and a test for the presence of *p*-hydroxybenzoic acid. HENRY L. SMITH. *Analyst* 41, 3-6(1916).—The m. ps. of samples of salicylic acid from a number of sources were detd. after drying *in vacuo* over H_2SO_4 , recrystn. from water and again drying. In all cases the acid m. 158.5° , both before and after crystn., which is distinctly higher than the figures usually given. The addition of *p*-hydroxybenzoic acid lowers the m. p. of salicylic acid. A mixt. of 99 parts salicylic and 1 part *p*-hydroxybenzoic m. $155-6^\circ$; 90 parts and 10 parts at $146-7^\circ$. The microscopic characters of the 2 acids if crystd. on a slide from dry ether are very dissimilar. Salicylic acid crystallizes in the well-known feathery or leaf-like crystals, the *p*-acid in small dense tufts. From a very dil soln. in commercial ether it may crystallize in a feathery form, due to the presence of water, but this is very different from salicylic acid. 5% of the *p*-acid can easily be detected by microscopic examn., but it is not easy to be certain if only 1% of the impurity is present. In the latter case, the formation of the basic Ca salt of salicylic acid $(OC_6H_4COO)Ca \cdot H_2O$, which is less sol. than the Ca salt of the *p*-acid, may be made use of to conc. the *p*-acid. A small amt. of the acid to be tested is mixed with $Ca(OH)_2$ and water, evapd. to dryness, and heated to 110° for an hr. After cooling, the mixt. is extd. with a little water. The aq. ext. is acidified and extd. with ether. The ethereal ext. is filtered and evapd. to dryness. The dry residue is then taken up in dry ether and prepd. for microscopic examn. as above described. P. B. DUNBAR.

Testing ether for narcosis. F. DIETZE. *Apoth. Ztg.* 30, 165-6(1915).—Pure ether tested in accordance with the method of Rogais (detection of H_2O_2) yields colorless ethereal layer, the aq. layer showing only a very faint yellowish color, while commercial Et_2O gives under similar treatment a reddish layer. As a result of D.'s expts., he would impose the following conditions: On treating 5 cc. Et_2O for narcosis with 1 cc. 0.1 *N* NH_4CNS soln. and shaking with 2 drops of a boiled and cooled (exclusion of air), acidified oxide-free $FeNH_4(SO_4)_2$ soln. (1 + 19), there should be no immediate reddening of the ethereal layer. W. O. E.

The active principle of *Baccharis cardifolia* (mio-mio). J. BRANDL AND G. SCHAEFTEL. Univ. Munich. *Arch. Pharm.* 253, 195-201(1915).—Administration of an aq. ext. of this Argentinian plant is fatal to rabbits, inducing hemorrhoidal gastroenteritis in these animals. An aq. ext. evapd. to dryness with $Ca(OH)_2$ and MgO , then treated with $C_6H_{11}OH$, *via* P. Arata, yielded colorless, non-toxic, non-alkaloidal crystals. The yellowish green mother liquor, however, proved to be toxic, as was also the ppt. formed on the addition of $Pb(OAc)_2$ to the aq. ext. Two kg. of the dried plant yielded to petr. ether 10 g. toxic, yellowish green baccharis oil (acid no., 7.19; sapon. no., 66.99; acid no. of the vol. fatty acids, 2.5; I no. of an old sample of oil, 93.56; of freshly prepd. oil, 81.60); 1.9 g. colorless, cryst., non-toxic compound ($C_{29}H_{48}OH$, m. 80° , stable toward alc. KOH, $KMnO_4$, CrO_3 , acetylating agents and nascent Br) and 2 g. non-toxic yellowish green resin. The toxic principle of the oil is destroyed by dil NaOH soln. W. O. E.

Oil from the seeds of *Strychnos nux vomica*. II. A. HEIDUSCHKA AND R. WALLENREUTER. Univ. Munich. *Arch. Pharm.* 253, 202-13(1915); cf. C. A. 7, 210.—The principal results of the investigation are summarized as follows: The unsaponifiable portion of the oil may be sepd. into the fractions, (a) a resinous portion, (b) a

phytosterol, m. 158° , (c) an alc., $C_{28}H_{47}OH$ (C_nH_{2n-12O}) or $C_{28}H_{49}OH$ (C_nH_{2n-10O}), m. 90° , $[\alpha]_D +90^{\circ}$, mol. wt. 496. The alc. contains no double bond and is probably related to amyirin. Esters of AcOH, propionic, benzoic and salicylic acids were prepd. Of the AcOH ester the mol. wt. = 512, $[\alpha]_D = +74.47$. The alc., $C_{28}H_{49}OH$, possesses a double bond in the side chain; its properties coincide in many respects with those of the sycoceryl alc. of De la Rue and Mueller. No sepn. of the unsaponifiable portions of the oil could be effected according to the method of Darmstaedter and Lifschuetz.

W. O. E.

Adaptability of the Röse-Gottlieb method for the estimation of fat and oil in certain pharmaceutical preparations. C. A. HACKMAN. *Chemist Druggist* 87, 19 (1915).—The Röse-Gottlieb method for fats involves the use of only very simple app. and affords the most rapid and accurate means for the detn. of oil in many pharm. preps., e. g., ext. of malt with cod liver oil, emulsions, etc.; it can also be used for the accurate detn. of cocoa butter in cocoa and chocolate. In adapting the method to substances other than milk (for which it was originally devised), it is important to keep the relative proportions between the water and the immiscible solvents const. Drawings of app. and detailed directions are given.

C. O. EWING.

Cinchona assay. P. J. KRUYSE. Amsterdam. *Chemist Druggist* 87, 155 (1915).—Moisten 6 g. coarsely ground bark with 1.5 cc. NH_4OH and 1.5 cc. H_2O , add 6 g. sand and grind to a fine powder; add 3 g. slaked lime mix, and add 3 cc. H_2O ; ext. $\frac{1}{2}$ hr. by boiling with 174 cc. Me_2CO , cool, make up to original vol., filter, evap. 150 cc. (= 5 g. sample) on a water bath. To the alkaloidal residue add 1 or 2 cc. HCl in 20 cc. H_2O , filter and shake out with Et_2O or $CHCl_3$ to remove fat. (This is optional with *Cinchona ledgeriana* but is essential with *C. succirubra*.) Neutralize to litmus with NH_4OH , boil, add 0.5 g. $(CO_2NH_4)_2$. If a large amt. of quinine is present, as in the case of *C. ledgeriana*, crystals of the oxalate ppt. as the soln. cools; if no ppt. appears in 5–10 min., as in the case of *C. succirubra*, add 220 mg. of quinine-HCl (in this case deduct 0.5% from the result), again boil and cool. The crystals, which in the case of *C. ledgeriana* consist of pure quinine oxalate, are filtered, washed (amt. of wash water not stated), dried and weighed. The wt. multiplied by 1.2 plus 20 mg. (allowance for soly. of quinine oxalate in wash water) gives equiv. of quinine sulfate in the bark. In the case of *C. succirubra*, the ppt., which consists of approx. 72.5% quinine oxalate, 23.6% cinchonidine oxalate, and 4% impurities, is dissolved in acid, neutralized, and 0.5 g. Na nitroprusside added; the pptd. quinine nitroprusside is filtered off, dried and weighed. The wt. multiplied by 1.04 plus 50 mg. (allowance for soly. of the oxalate and nitroprusside of quinine) gives the equiv. of quinine sulfate. "If the quantity of cinchonidine and cinchonine is also required, the cinchonidine can be detd. by pptg. it from the united filtrates as cinchonidine tartrate. The cinchonine can then easily be detd., as it is insol. in Et_2O ."

C. O. EWING.

Quantitative determination of salicylic acid in the presence of o-acetoxybenzoic acid. G. N. WATSON. *Druggists Circ.* 60, 7 (1916).—W. finds that Freyer's method for salicylic acid (*Chem. Ztg.* 20, 820 (1896)) can be used in the presence of $AcOC_6H_4CO_2H$.

C. O. EWING.

Otto of rose constants. ANON. *Perfumery Essent. Oil Record* 6, 275–6 (1915).—Genuine oils contain 65 to 75% geraniol and 30 to 40% citronellol. Limits of variation of physical consts. are as follows: sp. gr. 0.851 to 0.862, optical rotation -2 to -4° , n 1.458 to 1.862, m. p. is no longer important in detection of adulterants. A table shows the yearly variations in the consts. from 1909 to 1915.

C. O. EWING.

Colloidal silver for purposes of injection. FRITZ WISCHO. *Pharm. Post* 48, 469–70, 481–2 (1915).—Chemically pptd. colloidal Ag is superior to electrolytically prepd. Ag in that it can be dried without losing its colloidal state. After drying it

can again be taken up with water to form a colloidal soln. Dispargen is a chemically pptd. colloidal Ag prepn. of equal value with "electrargol" for purposes of injection. It contains about 30% of Ag, is not affected by strong mineral acids and but little by alkalis. It possesses bactericidal properties, an aq. soln. becoming sterile within half an hour. It is not hemolytic.

C. O. EWING.

The preparation of the volumetric solutions of the German Pharmacopoeia V. München Pharm. Assoc. *Pharm. Zentralhalle* 56, 403-6(1915).—Directions are given for prepg. the various volumetric solns. required. (No directions are given in the G. P.—ABSTR.)

C. O. EWING.

Volumetric solutions of the (German) Pharmacopoeia. WIEBLITZ. *Pharm. Zentralhalle* 56, 515-6(1915); cf. preceding abstract.—W. calls attention to improvements in some of the procedures above outlined.

C. O. EWING.

The composition of plagin. PRIESS. *Berl. klin. Wochschr.* 52, 552(1915).—Plagin is a parasiticide which has the following compn. by chem. analysis: Powdered anise 2, sugar 1, CaCO_3 2 and Na_2SiF_6 95%.

JULIAN H. LEWIS.

Candy medication. BERNARD FANTUS. Chicago Univ., Ill. *J. Am. Med. Assoc.* 66, 26-8(1916).—Directions are given for the prepn. of over 50 different medications for administration in candy form.

L. W. RIGGS.

Application of the biochemical method to the study of the kernels of cherry-laurel. MARC BRIDEL. *J. pharm. chim.* 12, 249-52(1915).—After destroying the enzymes by means of boiling alc., amygdalin (3.16%) and sucrose (2.26%) were extd. from the kernels, confirming Lehmann (1885). The march of optical rotation of aq. exts. (100 cc. from 100 g.) of kernels of cherry-laurel and bitter almonds and cherry-laurel leaves under the successive influence of invertin and of emulsin is tabulated. The compn. of the kernels of cherry-laurel and of bitter almonds is very similar, except that the former contain 19.2% more amygdalin than the latter, and the latter 23% more sucrose than the former. The glucoside of the leaves is prulaurasin (cf. C. A. 2, 1996).

S. WALDBOTT.

Preparation and physical properties of the essential oil of cadier (*Juniperus oxycedrus*). R. HUERRE. *J. pharm. chim.* 12, 273-83(1915).—The oil does not sep. easily from the woody tissue upon distn. with H_2O over direct fire. Prolonged maceration with H_2O (8 days) after 4 fractions were taken, raised the yield of the 5th. The total yield by the steam method, at different seasons from wood of the same territory (Var in S. France) was 3.1, 1.6 and 2.4%, the latter two 1 yr. apart. For good yield, the wood should be distd. soon after cutting. The crude oil gave $d_{15} 0.915-0.927$; $[\alpha]_D -31.42$, detd. in 10% soln. of 95% alc.; b. p. of 73% of the oil $260-280^\circ$; 50° , $b_{150} 158-161^\circ$. Cade oil is readily sol. in Et_2O , Me_2CO , CHCl_3 , sol. in 1 vol. of abs. EtOH , 95% EtOH , amyl alc., CCl_4 , cryst. AcOH , $\text{C}_6\text{H}_5\text{NH}_2$, xylene, C_6H_6 , toluene, with slight turbidity in 1 vol. of oil of turpentine, petroleum ether, CS_2 . Sol. in 12 vols of 90% alc. and 20 vols. of MeOH . In cade oil are readily sol. Me, Et and amyl salicylates, terpineol, eucalyptol, an equal wt. of camphor, $1/3$ its wt. of $\alpha\text{-C}_6\text{H}_4(\text{OH})_2$, 0.1 of homopyrocatechol. In less than their vol. of cade oil are sol.: creosote, liquid guaiacol the heavy wood creosote oils, veratrol, MeEt pyrocatechol, creosol, Me creosol, Et creosol, Et and Pr guaiacol, eugenol. To det. the best method of rectification of the oil, the relative vols. of distd. oil + H_2O were measured. If a mixt. of oil and H_2O is to be rectified over a direct fire, normal and not reduced pressure must be employed. Far better results are obtained when the steam is generated separately and conducted into the oil. Then reduced pressure (e. g., 400 mm., temp. of oil 86°) is of greater advantage than normal pressure. A higher temp. favorable theoretically, is not advised, due to possible color changes.

S. WALDBOTT.

Stainless iodine ointment (*unguentum iodi denigrescens*). W. R. PLATT AND HENRY L. SMITH. *Pharm. J.* 95, 544-6(1915).—This consists of a mixt. of free I, I compds. and soft paraffin. The proportions of the free and combined I vary according to the nature of the paraffin. It is not possible to make an ointment containing 5% I, combined or free, by the directions of the Brit. Pharm. Cod. If I is required to be combined, a soft paraffin with a sufficient amt. of unsatd. hydrocarbons should be chosen, and a "carrier" should be used. But even with ICl_3 , complete absorption does not occur for many hrs. If I is required in the free state, a more satd. paraffin, *e. g.*, one m. 35-36° and with I no. 2.80 (Wijs' soln.) makes an excellent prepn. Whether the I should be free or combined is an open question, but in the latter case, the I seems to be too firmly combined to be therapeutically available. S. WALDBOTT.

Cheltenham spa. ANON. Cheltenham. *Pharm. J.* 95, 571-2(1915).—Three waters are offered: Magnesian H_2O contains in grains per gal.: NaCl 27.980, NaBr 0.015, NaI 0.037, Na_2SO_4 60.893, Na silicate 1.469, K_2SO_4 4.779, LiCl traces, CaCO_3 36.372, CaSO_4 63.460, MgSO_4 117.659, MnCO_3 0.023, FeCO_3 0.038, AlPO_4 0.011 NH_4NO_3 0.018, org. matter, traces. This H_2O is also put up in concd. form, 16:1. Na_2SO_4 -water contains chiefly NaCl 390 and Na_2SO_4 155; an alk. water NaCl 466, Na_2SO_4 115, NaHCO_3 39 grains per gal. S. WALDBOTT.

Brazilian jalap. E. M. HOLMES. *Pharm. J.* 95, 671(1915).—Specimens diverted by the war from Hamburg to Liverpool, were recognized as the root of *Piptostegia pisonis* Mart., the true Brazilian jalap. F. W. Passmore obtained from it 20% of resin of which only 0.85% was Et_2O -sol. Thus, as a source of jalapin it is twice as valuable as Vera Cruz jalap, by the Brit. Pharm. standard. Its value is not lessened by its high content of ash, 8.9%. S. WALDBOTT.

Proposed substitute for preparations of valerian. THOMSON. Petrograd. *Pharmazeuticheski J.* 1915, 273; *J. pharm. chim.* 12, 358-63(1915).—*Bornyval* is bornyl isovalerate, sol. in EtOH, Et_2O and CHCl_3 , insol. in H_2O ; d_{15} 0.955, $[\alpha]_D$ -30.78 (+27.40, M. Siedler). Sapon. no. of commercial article 211.41, theory 235.29. It is sedative and tonic, but is decompd. by HCl in the stomach. *Neobornyval* is permanent towards HCl, decompd. by alkali. It is formed by heating equimol. amts. of bornyl chloroacetate and Na or K valerate. It is a colorless, odorless, tasteless, neutral liquid, sol. in organic solvents, insol. in H_2O , b. 284-6° with partial decompn., d_{15} 1.031, $[\alpha]_D$ +20.33°, sapon. no. 365.87, theory 378.38. Sapon. with KOH yields $\text{Me}_3\text{CHCH}_2\text{CO}_2\text{K}$ and $\text{CH}_2(\text{OH})\text{CO}_2\text{K}$; the latter may be pptd. by CaCl_2 . *Valissane*, bornyl bromoisovalerate, is a colorless, tasteless, aromatic liquid, of same solubilities as bornyval; $[\alpha]_D$ -25.31°, sapon. no. 331.55, theory 353.31; Br 23.4%, theory 25.2%. *Adamone*, bornyl dibromohydrocinnamate is prepd. by treating an EtOH soln. of borneol with $\text{C}_6\text{H}_5\text{CH}:\text{CHCO}_2\text{H}$ in presence of H_2SO_4 . The sepd. ester is treated cold with Br. Adamone is a white cryst. powder, insol. in H_2O , sol. in warm EtOH, Et_2O , CHCl_3 , m. 72°. Sapon. yields $\text{C}_6\text{H}_5\text{C}::\text{CCO}_2\text{K}$ which gives an orange color with alkali after oxidation with HNO_3 . S. WALDBOTT.

Composition of some specialties analyzed in Russia. *Pharmazeuticheski J.*; *J. pharm. chim.* 12, 269-71(1915).—*Modjardbe*. FeCO_3 15, essence of cubebs 3.73, alum 3.73, powdered ratanhia root 15, Canada balsam 15 g.; mix the first 4 in a mortar, gradually add and mix in the balsam, divide into pills each of 0.3 g. *Autobritt* (for shaving). BaSO_4 12, starch 46, ZnO 40, saponin 2 g.; powder and mix. *Bispol*. BiONO_3 2, powdered H_3BO_3 4, ZnO 4, Bi subgallate 2, lanolin 10, vaseline 20, Peru balsam 3 g. *Captol*. Vanilla 1, lactose 5, cryst. sugar 10, powdered cola 3, quinine-HBr 3, aspirin 6.6, salophen 6 g. Triturate vanilla with the sugars, screen through silk, mix in the other substances and divide into 1 g. packages. *Maltavène*. Mix equal wts. of barley flour, malt ext., goat's milk and eggs, add 15% of sugar and 17% of baker's yeast,

allow the paste to rise, form into cakes which are then dried and powdered. *Aniodol*. Dissolve 2.5 g. $(\text{CH}_2\text{O})_2$ with heat in 7.5 g. of glycerol, filter, mix with 2.5 g. essence of mustard, bring up to 1 l. with H_2O . 20 g. of this prepn. dild. in 1 l. of H_2O , is an antiseptic for surgical instruments, clothes, etc. S. WALDBOTT.

Color standards and cudbear. H. V. ARNY AND C. H. RING. *J. Am. Pharm. Assoc.* 4, 1294-99(1915).—A further report on the use of "Co-Fe-Cu" solns. of CoCl_2 , FeCl_3 and CuSO_4 in 1% of HCl , and of "Co-Cro-Cu" (*C. A.* 9, 2492) and of "Cro-Manganate" blends. For the latter a 0.001 *N* permanganate soln. and a 0.01 *N* dichromate soln. are used. These blends are unstable and must be used for matching within 1 or 2 hrs. after mixing. M. I. W.

Stability of preparations containing yellow phosphorus. H. ENGELHARDT AND O. E. WINTERS. *J. Am. Pharm. Assoc.* 4, 1450-7(1915).—A further report on the use of Cu salts in the estimation of yellow P (*C. A.* 9, 1553). CuCl_2 was found to be unsatisfactory while the $\text{Cu}(\text{NO}_3)_2$ method previously outlined gives uniformly trustworthy results. From a systematic study of a number of pharmaceutical prepn. containing yellow P the authors conclude that these prepn. keep well under ordinary conditions. Only those prepn. which contain org. matter are easily decomposed. M. I. W.

Sempervirine from gelsemium root. A. E. STEVENSON AND L. E. SAYRE. *J. Am. Pharm. Assoc.* 4, 1458-63.—Sempervirine may be sepd. from a mixt. of the combined alkaloids of gelsemium root by converting the alkaloid into the nitrate which is quite sol. in water and practically insol. in solns. containing NaNO_3 . Methods for the purification of sempervirine and for preparing the free alkaloid and some of its salts are discussed. From some preliminary pharmacological observations it would appear that salts of the alkaloids have no immediate toxic effect but 1 mg. of sempervirine-HCl in solns. was found to kill a 90 g. guinea pig in 48 hours. M. I. W.

Color reactions. E. A. RUDDIMAN. *J. Am. Pharm. Assoc.* 4, 1467-8(1915).—A review of the probable reasons for the widespread differences in the statements concerning the color produced by a given reagent on a given compound. M. I. W.

Estimation of atoxyl. H. ENGELHARDT AND O. E. WINTERS. *J. Am. Pharm. Assoc.* 4, 1468-71(1915).—A modification of the Ph. Germ. V. method for the estimation of atoxyl as outlined by Rupp and Lehmann (*C. A.* 5, 2694) works well and gives satisfactory results with simple tablets containing atoxyl. Bland's mass was found greatly to disturb the estn. with all of the available methods. M. I. W.

Tinctures. WILBUR L. SCOVILLE. *J. Am. Pharm. Assoc.* 4, 1472-6(1915).—A report of a comparative study of the relative stability of tinctures made by percolation of drugs and by diluting fluidextracts. The results are presented in the form of a table. M. I. W.

The estimation of morphine in pills and in tablets. H. W. JONES. *J. Am. Pharm. Assoc.* 4, 1477-9(1915).—A review of various methods proposed for extg. morphine with immiscible solvents. The method proposed by Williams (*C. A.* 8, 2920) which depends on the conversion of morphine into diacetylmorphine has been modified using NaHCO_3 instead of NH_4OH to liberate the alkaloid. The method so modified was found to give accurate and uniformly concordant results. M. I. W.

The retarding effect of certain substances on pepsin digestion. C. F. RAMSAY. *J. Am. Pharm. Assoc.* 5, 30-3(1916).—R. finds that comparatively small amounts of quite a number of salts in combination with pepsin interfere with or negative the test for pepsin but that the elixirs of iron and pepsin and of bismuth and pepsin of the National Formulary do not contain enough iron or bismuth to inhibit the activity of the pepsin, at least in so far as the pharmacopeial test is concerned. M. I. W.

Resin of jalap. J. PAUL SNYDER. *J. Am. Pharm. Assoc.* 5, 34-7(1916).—The U. S. P. standard of 35% of CHCl_3 -sol. matter in resin of jalap is indefinite, because the amt. depends entirely on the method employed for extg. the resin. Seven samples of resin of jalap yielded from 69.7 to 95.5% of CHCl_3 -sol. matter by the Soxhlet method and from 26.4 to 53.1% by the reflux method. The pharmacopeia should state definitely the amt. of sample and CHCl_3 to be used, the method to be employed and the length of time the resin should be treated with the solvent. M. I. W.

Pharmacopoeial standards for whiskey and brandy. GEORGE M. BERRINGER. *J. Am. Pharm. Assoc.* 5, 54-65(1916); *Am. J. Pharm.* 88, 49-65(1916).—Proposed monographs including definitions, descriptions and tests for whiskey and brandy with a table giving a synopsis of the examn. of 40 samples of distd. spirits. M. I. W.

The nephelometric determination of small amounts of essential oils. A. G. WOODMAN, R. T. GOOKIN AND L. J. HEATH. *J. Ind. Eng. Chem.* 8, 128-31(1915).—When the methods most commonly employed to det. essential oils (extrn., pptn. and subsequent measuring) are not applicable because of the small amts. of oil present, dependable results may be had with oils that form an emulsion with water by detg. the amt. of light reflected from a column of this emulsion. The candle turbidimeter was not found suitable for this purpose. A nephelometer as described by Kober (*C. A.* 7, 3981) was found to give satisfactory results. Peppermint oil, nutmeg oil, anise oil and oil of rose can be detd. with great accuracy by the nephelometric method in concns. up to 1%. The method is not applicable to essential oils which do not form an emulsion on adding water to their alc. solns. The detn. ordinarily requires less than half hour for its completion. M. I. W.

On the chemical constituent of "Amacha" (*Hydrangea tunbergii*). HIDEO MANIWA. *J. Pharm. Soc. Japan* 1915, 1399.—The dried leaves contain a characteristic sweet substance having the formula $\text{C}_{16}\text{H}_{14}\text{O}_6$. This substance contains 2 hydroxyl groups and yields a diacetyl derivative (m. 144°) and a dibenzoyl derivative (m. 162°). The phenolic character of the substance is further characterized by its yielding a violet color with FeCl_3 and by being sol. in a cold soln. of alkali. M. I. W.

Approved methods of physiologic standardization of drugs. CHARLES S. CHASE. *J. Am. Pharm. Assoc.* 4, 1289-93(1915).—A review. M. I. W.

Tobacco. J. K. PROBST. U. S., 1,168,029, Jan. 11. Cured tobacco leaves are subjected to vapors generated from salt water and from an NH_4OAc soln. to promote "after-fermentation."

Tyrosine-mercury compound. H. BUCHTALA. U. S., 1,167,622, Jan. 11. A compd. of the formula $\text{C}_9\text{H}_9\text{O}_2\text{NHg}$ is prepd. by heating a soln. of tyrosine with Hg oxide or acetate and is employed in an alk. soln. prepd. with 1% NaOH or KOH as a medicinal agent in the treatment of gonorrhea.

Plastic compositions. W. HARBUTT. Brit., 19,211, Aug. 28, 1914. A plastic compn. comprizes a mixt. of permanently plastic material of the kind usually employed for modelling, such as "plasticine," and fibrous material, such as wool or cotton-wool. "Plasticine" is stated to have as its chief constituents S and pure vegetable oils. Suitable proportions are 1 lb. of wool per cwt. of "plasticine." The compn. is applicable for ear-stoppings for preventing gun deafness, for resetting broken bones, and, when rolled into sheets, as surgical bandages.

Urethans of the phenyl glyceryl ethers. BAYER & Co. Ger., 284,975, Sept. 2, 1913. These urethans are obtained when phenyl glyceryl ethers, in which the phenyl groups can be substituted by homologs and substitution products, are converted into simple or substituted urethans according to the usual methods.

Carbonic acid derivative of sodium 2-phenylquinoline-4-carboxylate. CHEM. FABRIK AUF ACTIEN (v. E. SCHERING). Ger., 285,499, Dec. 28, 1913. This product is obtained by acting on Na 2-phenylquinoline-4-carboxylate with CO_2 , or by treating 2-phenylquinoline-4-carboxylic acid with Na_2CO_3 , or with NaHCO_3 , or by effecting a reaction between NaHCO_3 and 2-phenylquinoline-4-carboxylates. Cf. C. A. 9, 1097.

Bismethylaminotetraaminoarsenobenzene. C. F. BOEHRINGER & SÖHNE. Ger., 285,572, May 14, 1912. Cf. Brit., 996, 1913 (C. A. 8, 2603).

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Perkin medal award (to Dr. L. H. Baekeland). Introductory address. W. M. GROSVENOR. *J. Ind. Eng. Chem.* 8, 177-8(1916). Presentation address. C. F. CHANDLER. *Ibid* 178-82.—A review of the life and works of Dr. L. H. Baekeland is included in this address. Address of acceptance. L. H. BAEKELAND. *Ibid* 182. The discovery of Dr. Baekeland. RICHARD A. ANTHONY. *Ibid* 182-3. An appreciation of Dr. Baekeland. E. H. HOOKER. *Ibid* 183-4. Practical life as a complement to university education. Medal address. L. H. BAEKELAND. *Ibid* 184-90.

E. J. C.

The role of chemistry in the war. ALLERTON S. CUSHMAN. *J. Franklin Inst.* 181, 163-90(1916).

E. J. C.

The graphics of blending in chemical industries. F. G. DONNAN. *J. Soc. Chem. Ind.* 35, 3-7(1916).—A general geometric method is indicated for the solution of a certain class of problems occurring in technical chemistry. Such concrete illustrations as are given refer to the soap mfg. industry.

E. J. C.

A further innovation in the manufacture of hydrochloric acid. H. FRIEDRICH. Biebrich. *Chem. Ztg.* 40, 10-11(1916); cf. C. A. 7, 3201.—The app. is designed to wash and cool the HCl gas and remove As without loss of HCl . The gas enters at the top of a central chamber, passes to the bottom and out into side chambers, to the top of these then down the next adjoining chamber, from the bottom of which it goes to the absorber. In the top of each chamber are sprays through which H_2SO_4 is circulated until it becomes satd. with As when it is removed and the As removed with H_2S , a fresh lot of H_2SO_4 being used in the meantime.

J. H. MOORE.

Conversion of ammonia into nitric acid. KARL KAISER, Charlottenburg; BRUNO WÄSER, Brieg; BERLIN-ANHALTISCHE MASCHINENBAU AKT.-GES. *Chem. Ztg.* 40, 14(1916).—Wäser's statement to the contrary notwithstanding (cf. *Chem. Ztg.* 39, 916(1915)), Kaiser claims to oxidize NH_3 at a cost of 1.25 kg. coke per kg. NH_3 , plus power to drive fans, with a guaranteed yield of 90-5%. The B.-A. Masch. A.-G. built over 30 plants during last yr. capable of oxidizing over 12 million kg. NH_3 by the Frank-Caro process, equalling Kaiser's guaranteed yield and have under construction app. for oxidizing 17 mill. kg. per yr. Cf. C. A. 6, 2302; 7, 2456; 8, 214, 2605; 9, 356.

J. H. MOORE.

The acetic fermentation of *Fucus evanescence* (Hibatsunomata). E. TAKAHASHI. *J. Chem. Ind. Japan* 19, 30-41(1916).—T.'s expts. show that *Fucus evanescence*, a seaweed which grows along the eastern coast of Hokkaido, will ferment with the production of AcOH if allowed to stand with a little lime and some water added occasionally. The AcOH obtained contains a small amt. of propionic acid. The proper amt. of lime to add is about 3-5% of the dry matter and it is advisable to add it 3-4 times in small quantities. The suitable time needed for fermentation is about 2 weeks at

30° and 3-4 weeks at 20°. As the quantity of acid is increased by the addition of fucose to samples this sugar probably has some relation to the acid fermentation.

E. J. C.

Production of ammonia from cyanamide. W. S. LANDIS. *J. Ind. Eng. Chem.* 8, 156-60(1916); *Met. Chem. Eng.* 14, 87-90(1916); cf. *C. A.* 9, 2699, 3333.—The raw materials are cyanamide or lime nitrogen (cf. *C. A.* 9, 1719), containing about 25% of N as CaCN_2 , 12% CaO , 12% C, the remainder being impurities derived from the raw materials used in its manufacture, Na_2CO_3 and $\text{Ca}(\text{OH})_2$, 3.5 and 2%, respectively, of the wt. of cyanamide used. On treating CaCN_2 with steam NH_3 is evolved according to the equation $\text{CaCN}_2 + 3\text{H}_2\text{O} = \text{CaCO}_3 + 2\text{NH}_3$, which is almost quant. when carried out as described for this process. A unit of the app. consists of a steel autoclave 6 ft. in diameter and 21 ft. high, capable of withstanding a pressure of 300 lbs. per sq. in., and furnished with an effective stirring app. Into this autoclave are charged 12,000 lbs. of mother liquor from a previous operation (fresh water to start) and 7000 to 8000 lbs. of cyanamide are fed in over a period of about 1 hr. with constant stirring. As a slight amt. of CaC_2 is present, C_2H_2 is formed during the charging and must be removed by a ventilating system which will insure non-explosive mixts. with air. Na_2CO_3 and $\text{Ca}(\text{OH})_2$ are next added to increase the efficiency of NH_3 evolution, principally by preventing the formation of polymeric forms of cyanamide compds., which are more difficult to transform into NH_3 . The autoclave is then closed and steam is admitted for about 15 min. until the pressure reaches 3-4 atm., which gives a temp. sufficient to start the reaction at a fair rate of speed. This reaction is strongly exothermic, generating steam and NH_3 in the autoclave so rapidly that the pressure rises to 12 or 15 atm. in about 20 min. even with the relief valve open. The pressure then slowly decreases, the rate of discharge being regulated so as to maintain a constant pressure in the NH_3 line. At about 90 min. from the start the evolution of gas ceases. Live steam is next admitted up to 6 or 8 atm. and the NH_3 valves opened for a second discharge. A third steaming rarely yields over 2% of the total NH_3 . The mud is run from the bottom of the autoclave to filters of the "Nutsche" type, the filtrate and washings being used to dissolve the next batch. The lime sludge when dried contains 65% CaO as CaCO_3 and $\text{Ca}(\text{OH})_2$, and less than 0.2% of NH_3 . Methods of handling the NH_3 for the production of different chemicals are given, also descriptions of plants with operating costs. Very pure NH_3 is obtained much cheaper by this process than from gas liquor or by-products of coke ovens.

L. W. RIGGS.

Potash in certain copper ores and tailings. B. S. BUTLER. *Mining Eng. World* 43, 935-6(1915).—A commercially successful method for recovering K_2O from silicates would make available the large amts. contained in the finely ground tailings produced by concn. methods of Cu reduction. Analyses show the K_2O content of certain tailings from Western mining regions to be as high as 6.81%.

H. L. OLIN.

The fused "foundry salt" of the Heilbronn salt works, and its suitability for food and confection purposes. K. B. LEHMANN. *Würzburg. Chem. Zig.* 40, 6-7, 28-9(1916).—The salt, containing 99.88-99.95% NaCl , is prepd. by crushing rock salt and fusing it in a 2-stage Siemens furnace. On the upper stage the fused NaCl runs away from most of the impurities and collects in the lower, basin-shaped stage where it is treated with compressed air for 15-20 min., with addition of small amts. of CaO , to remove org. matter and Fe and Al. After settling, the H_2O -clear melt is discharged through Fe troughs into rotary Fe pans provided with rakes, where it is slowly granulated. Scrapers in the pans discharge it into revolving screens which sep. it into 4 or 5 sizes; it then goes to mechanical packers. Comparative analyses of this and crystd. NaCl are given, and the results of an investigation of the impurities show it to be especially suitable for food purposes.

J. H. MOORE.

The application of compressed nitrogen. ANON. *Naturwissenschaften* 3, 674 (1915).—Until recently the price of N was 1 to 2 marks per cu. m. The Braun method of cheap N production (see Ger. pat. No. 215,608 (C. A. 4, 653)) has brought the price in Berlin down to about $\frac{1}{4}$ c. per cu. m. for very highly compressed N (150 to 200 atms.) and $\frac{1}{10}$ c. for N at 6 to 8 atms. Compressed N is used in place of air in compressed air motors; 1 h. p.-hr. requires about 10–12 cu. m. N. The N motor is decidedly safer and cleaner than the gasoline motor. Another application of this N is in the preservation of foodstuffs. C. G. F.

History of the manufacture of hydrogen for military purposes. A. SANDER. *J. Gasbel.* 58, 637–43 (1915).—A review of the principal processes for the manuf. of H_2 on the large scale, and of the methods for handling it in the field. W. L. B.

New combinations for various artificial products. H. PUFÄHL. *Kunststoffe* 6, 7–9 (1916).—A brief review and discussion of the processes for making artificial ivory, wood products, horn, amber, etc., from such materials as celluloid, wood meal, paper refuse, papiermaché, galalith, copal, etc. F. W. SMITHER.

Annual report of the chief inspector of factories and workshops for 1914. 133 pp.; *J. Soc. Chem. Ind.* 34, 1230–2 (1915).—The total number of factories and workshops registered (British Isles) at the end of the yr. was 276,855; 1287 fatal and 51,276 non-fatal accidents are reported. Accidents due to "scaffolds" and "slips" in blast furnaces appear to be more common in Scotland than in England, probably owing to the greater use of coal and increase in the quantity of small ore. The tendency to form "scaffolds" may be diminished by briquetting or nodulizing fine ores, but serious results to workmen as a result of explosions following "slips" can be prevented only by installation of automatic charging app. *Explosions of dust, gas, etc.* Tests by Wheeler (C. A. 7, 2686) at Eskmeals showed that samples of dust from paper-tube works yielded 24 to 54%, and dust from rag chopping and sorting rooms of paper mills yielded 27 to 77% of ash; those yielding less than 32% of ash were classed as dangerous. Tapioca dust, though yielding only 2% of ash was not dangerous, the gases evolved on heating containing about 30% CO_2 . Dusts from the mixing and spice rooms of a cattle-food factory and from the grinding room of a provender mill proved to be dangerous dusts. Pitch dust is more highly inflammable than coal dust and almost as dangerous as sugar dust. Two explosions are reported where "diazo-dye substances with aniline and naphthalene bases" were being dry ground in drum grinders. Some of these substances appear to undergo mol. change when heated, and it is suggested that frictional heat generated during grinding might be sufficient to start chem. action which, in a closed space, might become so violent as to burst the machine. A serious coal-dust explosion occurred at a cement works in S. Wales; difficulty was experienced in closing a large valve at the bottom of a coal-dust storage hopper, and the cover of the valve-box was removed before the valve was closed, whereupon a large quantity of coal dust escaped, and fell over the edge of the working platform onto the rotary kiln below, where it immediately ignited. In addition to the provision of padlocks for the valve covers and efficient means of escape from each floor of the kiln house, it is recommended that screens be installed below the coal-dust shoots to remove foreign material liable to cause obstruction in conveyors, valves, etc., and that the coal grinding and feeding plant be completely sepd., by concrete partitions, from the rotary kiln. An explosion of picric acid dust caused 8 deaths and injuries to many persons; dry picric acid was being ground in a small hand grinding mill in a room which was impregnated with fine dust, and it is presumed that a spark was generated (cf. C. A. 9, 716, 1995). To prevent explosions arising from the use of compressed gases in cylinders, it has been suggested that different gases should be stored in differently colored cylinders, but a case is cited to show that this precaution is not adequate. It is recommended that

(1) Residual gas or air in cylinders returned to the works should be removed before the cylinders are re-charged. (2) Cylinders of different shapes should be used for different gases. (3) The cylinders should be numbered and registered. (4) Cylinders for different gases should have screwed connections differing in diameter as well as in direction of thread. Two explosions of air receivers connected with air compressors were due to the ignition of a mixt. of air and finely divided lubricating oil or oil vapor (*C. A.* 8, 824). Attention is directed to the need of great care in dealing with old drums and tanks which may have contained acids, chemicals, or inflammable spirits. In a works in the Swansea district, an old drum, which had contained H_2SO_4 , was being pierced by a pick prior to charging into a steel furnace. The drum contained H_2 , which was ignited by a spark or otherwise, and the workman was killed by the resulting explosion.

Factories working under regulations. Out of 111 coarse-ware potteries, raw lead is now used in only 18; and out of 465 other potteries, including general fine household earthenware and chinaware manufactories, leadless glazes or glazes containing not more than 5% of "soluble lead" (see Thorpe, *J. Soc. Chem. Ind.* 20, 475(1901)) are used in 106. The av. efficiency of the local exhaust app. used in potteries for removing dust showed a decided increase during 1914. In brass-casting establishments the use of mechanical ventilation for removing fumes is extending, but this is not always satisfactory when the roof is low and flat. Bronzing is becoming more concd. in larger factories equipped with modern machines and benches provided with exhaust ventilation. The quantity of bronzed ware has diminished since the outbreak of war, as all the powder used was imported from Germany. The use of leadless glaze in vitreous enamelling is extending.

Lead poisoning. The total number of cases in 1914 was 445 (28 fatal). Poisoning has markedly diminished in industries where periodical medical examn. is required and where exhaust ventilation can be applied locally, *e. g.*, in the smelting of metals, tinning, white lead, pottery, and paints and colors, whereas little alteration in the figures is shown in industries where these precautions can be applied only to a slight extent, *e. g.*, printing, plumbing, painting, etc. The principal cause of Pb poisoning is the inhalation of fumes or dust of the metal or its compds. Goadby and Oxley (*C. A.* 9, 824) found that the treatment in a bi-polar elec. bath, recommended by Oliver (*C. A.* 8, 1162, 1333, 3126), was of no value for removing Pb from the animal system, and this conclusion has been confirmed in works where the treatment has been systematically tried.

Phosphorus poisoning. The manufacture of H_2 by the action of NaOH on ferro-silicon is associated with grave danger owing to the liberation of PH_3 (*cf.* Pellew, *C. A.* 8, 3532), and the following precautions should be observed: (1) The NaOH and Fe-Si should be stored in sep. places. (2) The Fe-Si in store should be kept dry. (3) It should not be manipulated by workmen whose hands or clothes are soiled with NaOH. (4) Waste material from the H_2 -generating tank should be conveyed into the open air through a closed pipe. (5) Free ventilation should be provided whenever gas is being generated. (6) Workmen should be warned of the danger of inhaling the gas.

Arsenic poisoning. One case occurred during the cleaning of an $(\text{NH}_4)_2\text{SO}_4$ saturator in a shale-oil works. The acid liquor contained 179.5 grains As_2O_3 per gal., and poisoning was probably due to AsH_3 produced by the action of this liquid on a galvanized Fe pail used by the workman. It is now required that wooden pails be substituted for metal pails in the sulfate house and in tanks which have contained H_2SO_4 or HCl .

Mercury poisoning. Of the 10 cases reported, 4 occurred in the manufacture of thermometers, 2 from Hg fulminate dust in the filling of detonators, 2 in the manufacture of felt hats, and 1 each in the manufacture of $\text{Hg}(\text{CN})_2$ and HgO paint.

Anthrax. 54 cases (7 fatal) are reported. **Fumes and gases.** Cases are reported as follows (number of deaths given in parentheses): CO: blast-furnace gas, 20 (6); power gas (suction, producer, Moud, Dowson), 21; coal gas, 7 (1); other cases, 14 (2); CO_2 , 3 (1); H_2S ,

22 (3); SO_2 , 1; Cl and HCl fumes, 2; nitrous fumes, 9 (2); NH_3 , 4 (1); C_6H_6 , naphtha, and petrol, 4 (2); NO_2 and NH_3 derivs. of C_6H_6 , 38 (2); trichloroethylene, 1 (1); tetrachloroethane, 25 (4); other cases, 3. Administration of O from cylinders fitted with pressure-reducing devices has frequently proved effective not only in cases of CO poisoning, but also in poisoning from H_2S and nitrous fumes. Of the 38 cases of poisoning by NH_3 and NO_2 derivs. of C_6H_6 , 28 were due to the use of dinitro-compds. in the manufacture of a particular explosive in 1 factory. To render the explosive safer for use in mines, a certain percentage of a deliquescent substance was added and this rendered the product more easily absorbed by the skin. *Industrial eczema.* The following precautionary measures are recommended for use where workers come in contact with chromic acid or its salts: (1) Daily inspection of the hands and arms of the workers. (2) Even the smallest abrasion should be washed in running H_2O and immediately covered by collodion or by a dressing of boracic lint or cyanide gauze under an impervious waterproof dressing; the dressing should be changed daily. (3) Long rubber gloves should be worn. (4) The arms of the workmen should be smeared with a suitable ointment, *e. g.*, a mixt. of 3 parts of paraffinum molle, B. P., and 1 part of lanolin, with the addition of 5 drops of 90% phenol to every 4 oz.; or a mixt. of "mineral lard," 3 lbs.; paraffin wax, 7 oz.; and "cyllin," 1.5 oz. For protecting the skin against oil of turpentine a mixt. of lanolin and castor oil (equal parts, or 50:100), to which 1-2% of phenol is added, is recommended. *Results of five years' notification of lead poisoning.* It appears from the tabulated figures that the continued diminution in the number of cases has not been accompanied by a corresponding fall in the number of deaths reported, and this is attributed to the fact that, following on the operation of the Workmen's Compensation Act of 1906, deaths of Pb workers suffering not only from chronic nephritis, but also from phthisis and pneumonia have been certified more frequently than formerly as due to Pb poisoning. *Tetrachloroethane poisoning.* The following precautionary measures have been adopted: (1) Operations in which varnish containing tetrachloroethane is used are carried out in a separate shop or a screened-off portion of a larger shop. (2) Exhaust fans are provided at the floor level. (3) No work people are allowed to remain in the shop during meal times. According to expts. made by Lehmann in Germany, the vapor of tetrachloroethane is about 9 times as poisonous as that of CCl_4 and about 4 times as poisonous as that of CHCl_3 . Cf. Gray, *J. Soc. Chem. Ind.* 34, 1125 (1915). F. W. SMITHER.

Furnace for making hydrochloric acid. W. M. KRICKBAUM. U. S., 1,167,763,

Jan. 11. A charge of NaCl and H_2SO_4 is fed into the shallow pot 4 through chutes 33 and 34 from a feed conveyor 32. This pot is heated from two fire boxes 6 and shovels 19 gradually move the charge toward the outer calcining bed 5, from the edge of which it is finally ejected into a discharge chute and the gaseous reaction product is led off through a conduit in the upper wall of the reaction chamber.

Phosphoric acid. I. HECHENBLEIKNER. U. S., 1,167,755, Jan. 11. A charge of phosphate rock, SiO_2 and C is heated in the electric furnace 1 with electrodes 3 to form CaSiO_3 , CO and P and the CO and P are passed through a mixt. of phosphate rock and SiO_2 in the passage 9 (which is lined with fire-brick) and oxidized to CO_2 and P_2O_5

by air admitted through the inlets 7, passed through the dust collector 15 and led off to make H_2PO_4 . C is fed in at 6 and phosphate and SiO_2 at 16, passing in a continuous stream to the furnace 1. The conduit 9 is rotated on rollers 10.

Ammonium phosphate. F. S. WASHBURN. U. S., 1,167,788, Jan. 11. A portion of crude phosphoric acid

soln. is treated with steam carrying an excess of NH_3 to produce a soln. high in $(\text{NH}_4)_2\text{HPO}_4$ and the unabsorbed NH_3 is passed into an excess of similar crude H_2PO_4 to form $\text{NH}_4\text{H}_2\text{PO}_4$. The latter is returned to the supply of crude acid for further treatment and the $(\text{NH}_4)_2\text{HPO}_4$ soln. is treated with H_2PO_4 slightly in excess of that required to produce a soln. of $\text{NH}_4\text{H}_2\text{PO}_4$ free from $(\text{NH}_4)_2\text{HPO}_4$. Cf. C. A. 9, 1978.

Phosphorus and phosphides. J. J. GRAY, JR. U. S., 1,168,495, Jan. 18. A blast furnace is charged with a mixt. of $\text{Ca}_3(\text{PO}_4)_2$ with sufficient SiO_2 to liberate all or a portion of the P, and with sufficient Fe_2O_3 to combine with about 40-50% of the liberated P to produce phosphide and give fluidity to the slag formed. C is added to the charge and air is supplied in limited amts. so as to maintain a reducing atm. in the furnace. CaF_2 and CaCO_3 are used as flux.

Producing ferrous sulfide. N. PETINOT. U. S., 1,169,093, Jan. 18. Fe and Fe pyrites ore are smelted together with slag-forming materials in an elec. furnace.

Apparatus for preparing nickel for use as a catalyzer. C. B. MOREY and C. R. CRAINE. U. S., 1,167,915, Jan. 11. An inert carrier impregnated with a catalytic

metal salt or compd., *e. g.*, diatomaceous earth impregnated with $\text{Ni}(\text{OH})_2$, is passed from a hopper 11 through a tube 10, heated by Bunsen burners and encased in fire brick, while H or other reducing gas is circulated through the tube from the gas holder 13 to which the excess is returned after passing through a purifier 18. The catalyzer produced is collected in the chamber 15 without exposure to the air.

Lampblack and hydrogen. R. H. BROWNLEE and R. H. UHLINGER. U. S., 1,168,931, Jan. 18. Natural gas or other gaseous or gasified hydrocarbon is passed over highly heated refractory material in a reaction tower, under pressure and with exclusion of air, and

the C and H produced are sepd. by cooling and washing. Cf. C. A. 9, 516.

Treating kelp. J. W. CHENEY. U. S., 1,168,785, Jan. 18. Kelp is dried and roasted below an incinerating temp. to drive off volatile constituents such as creosote, acetone and alc. The residue is incinerated to ash while constantly agitated, salts are dissolved out and recovered by crystn. and I is distd. from the remaining material.

Heat insulating material. J. E. LAPPEN. U. S., 1,169,079, Jan. 18. Degummed flax fiber and shives, mixed with short-fibered straw, beaten to consistency of "half

stock" with H_2O 500, is mixed with melted petroleum tailings 40, crude paraffin 20, mineral wool 500, and alum 7 parts, and the mixt. is molded into sheets or boards. Cf. C. A. 9, 722.

Internal-combustion engine cleanser. W. F. C. M. McCARTY. U. S., 1,167,770, Jan. 11. A mixt. of acetone 1 gal., ether 3-5 gals., H_2O_2 12 oz., CH_3NO_2 4 oz. and nitroglycerin $1/2$ oz. is added to the fuel used in internal-combustion engines, in the proportion of about 1 to 10, to clean the cylinders. The nitroglycerin may be omitted and the compn. used as a solvent of oils, fats or waxes.

Phenolic condensation product used in gear-wheels. F. CONRAD. U. S., 1,167,742-3, Jan. 11. Gears are formed of laminations of cloth or paper with a binder of phenolic condensation product.

Phenol resin phonograph record. J. W. AYLSWORTH. U. S., 1,167,468, Jan. 11. The main portion of the records is formed of a mixt. of a fusible phenolic resin with a filler such as wood flour and the surface of the record is made of hard infusible phenolic resin sufficiently plastic when heated to be pressed and molded. Cf. C. A. 9, 2432.

Casein. L. H. REUTER. U. S., 1,167,434, Jan. 11. Buttermilk is treated with a soln. of Na_2CO_3 and $NaCOOH$, filtered, and H_2SO_4 mixed with $HCOOH$ is added to the filtrate, the ppt. is washed with dil. $HCOOH$, dried, ground and mixed with CaO or borax to prepare it for use as a glue or in paints.

Charges for extincteurs. F. C. PALETHORPE and D. ROWE. Brit., 19,096, Aug. 26, 1914. In charges for extincteurs of the kind in which a foam-producing substance, such as *Quillaia* or Panama bark, is employed, the alk. charge consists of approx. 1 oz. of *Quillaia* bark to each lb. of $NaHCO_3$. This quantity of the mixt. is used with about 1.25 gals of H_2O .

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The influence of the thermal coefficient of expansion of hard porcelain on the burning temperature. R. RIEKE AND W. STEGER. *Sprechsaal* 48, 297(1915).—Underburned porcelain frequently shows crazing which disappears on reburning. The coeff. of expansion of a body ($20-100^\circ$) decreased with increased burning temp. Repeated burning also decreased the coeff. Since difference between the coeff. of body and glaze increases with higher burning temp. the crazing of underburned ware is not due to the effect of the coeff. of expansion of the body. R. K. HURSH.

The viscosity of porcelain bodies high in feldspar. A. V. BLEININGER AND C. S. KINNISON. Bur. Standards, *Tech. Paper* No. 52(1915); see C. A. 10, 516.

R. K. HURSH.

Observations on blisters. H. KNOBLAUCH. *Sprechsaal* 48, 185-6(1915).—Some methods of overcoming and preventing blisters in glass, due to incomplete decompn. of Na_2SO_4 . Fine charcoal of the proper amt. should be moistened and mixed with the Na_2SO_4 before adding the sand and lime. Both excess and deficiency of C are detrimental to the glass. The proper amount depends upon the temp. and the compn. of furnace gases. R. K. HURSH.

Kilns and kiln burning. ANON. Brit. *Clayworker* 20-23(1912-1915).—An excellent general summary covering kilns of all kinds as follows: single up-draft, *idem* 20, 153-6; shaft, *idem* 20, 178-82; flues, bags, etc., *idem* 20, 205-8; rectangular and round down-draft, *idem* 20, 237-9, 256-9, 282-5; 21, 4-6, 38-41; kiln bottoms, crowns and flues, *idem* 21, 64-8; double and horizontal draft, *idem* 21, 90-4; semi-continuous. Cassel, *idem* 21, 117-20; New Castle, Two-Stage Kilns, *idem* 21, 142-5, 168-70; triple

and connected round kilns, *idem* 21, 170-1, 194-7, 220-1; connected rectangular kilns, *idem* 21, 221-3, 246-9; tunnel kilns, *idem* 21, 249, 272-5, 298-302; 22, 4-8, 60-1, 86-9, 112-5; Haigh kiln, *idem* 22, 113-4; Buhner kiln, *idem* 22, 114-5, 138; Chamber kilns, *idem* 22, 138-42, 164-8; hot-air flues, *idem* 22, 190-4, 216-20; steam flues, *idem* 22, 243-6; oil-fired kilns, *idem* 22, 277-8; gas-fired kilns, *idem* 22, 278-9, 294-7, 320-3; 23, 4-7, 30-3, 60-4, 116-7, 140-1, 164-6; semi-gas-fired kilns, *idem* 23, 7; Dunnachie and Mendheim kilns, *idem* 23, 140-1, 164; gas-fired muffle kilns, *idem* 23, 166, 188-9; coal vs. gas firing, *idem* 23, 189-90, 212; tunnel kilns, *idem* 23, 212-5, 235-9, 260-3; 24, 4; Dressler kiln, *idem* 23, 262-3; muffle kilns, *idem* 24, 5, 21-2, 40-1, 60-1, 80-2; gas-fired muffle kilns, *idem* 24, 61, 80-2; rotary kilns, *idem* 24, 100-3; Summary of types of kilns, *idem* 24, 100-1. The most suitable kilns for the various industries are as follows: Pottery (including glazed tiles) up-draft or connected ovens, or possibly tunnel kilns; terra-cotta facing bricks and roofing tiles, round down-draft or Newcastle kilns, or preferably continuous chamber kilns, if the output is sufficiently large; red bricks from Staffordshire marls, muffle kilns must be used; sanitary pipes (salt-glazed), round down-draft kilns; glazed goods of large size, muffle kilns, preferably connected; firebricks, Newcastle or gas-fired continuous chamber kilns; engineering bricks, rectangular kilns, similar to Newcastle type, but with side fires, or true Newcastle kilns. If the output is large, a special type of continuous chamber kiln is preferable; common bricks, Scotch or Newcastle kilns, but if the output is sufficiently large continuous kilns are in every way preferable.

The experimental determination of the effect of varying the percentage of water in concrete. R. K. SKELTON. *Surveyor* 48, 328-30(1915).—Tables and curves are given to show variations in strength of briquets, 6 in. cubes, and 2 in. by 3½ in. by 3 ft. bars reinforced by two 1⅛ in. round rods, when made with amounts of water varying from 20 to 42.5%. The mixt. was 1:2:4, cement, sand and stone. The 27.5% mixt. was best; those with more and less water were weaker. The 42.5% mixt. cube had only about 0.25 the strength of the 27.5% cube at the end of 7 days, but after 60 days was nearly half as strong. Where very wet mixts. are used, as with chuting devices, allowance should be made for the less strength of the very wet concrete and the removal of the forms should be delayed.

W. D. COLLINS.

Plaster of Paris and the effect of foreign substances. E. L. TROXELL. Univ. Mich. *Am. J. Sci.* 41, 198-210(1916).—This paper has especial reference to the use of plaster of Paris in mending and restoring paleontologic specimens. Briquets used in this study were 1 sq. in. in cross section. Pure plaster briquets possessed an av. strength of about 400 lbs., those made with a minimum of water being about 100 lbs. stronger than those in which an excess of water was used. Plaster is most sol. and mixes most readily with water at 80°. Briquets made with hot water showed an av. of 60 lbs. in strength above those made with cold water. Soaking in water produces temporary weakening but if the briquets are not handled while wet, the strength is fully regained on drying. Plaster once started to set hardens very rapidly after being disturbed, as each crystal already formed furnishes a nucleus around which the mass quickly accumulates. A quick-setting plaster may be made by mixing in dust ground

from a piece of set plaster, thus supplying the nuclei. Pure plaster can be retempered provided it is soft enough to be worked. Fifty min. appears to be the time limit. Dry colors mixed with dry plaster give best results. Bone black, burnt and raw sienna, and Venetian red are recommended. Plaster made up with dextrin soln. is much weakened; even "a $1/48$ soln." reduced the strength nearly one-half. Gum arabic reduces the strength somewhat as dextrin, but is valuable for surface hardening, and is used in restoring small irregular bodies where the surface area is large in proportion to the vol. Although glue weakens plaster decidedly, it has many applications in mending specimens. Its chief objection is its hygroscopic character, which may frequently be overcome by covering the glue seam with shellac. Expts. with water glass for hardening plaster gave unfavorable results. $MgOHCl$ promises to be more efficient in some special uses than plaster of Paris.

L. W. RIGGS.

Aggregates and fillers for bituminous road construction. E. J. LOVEGROVE. *Surveyor* 48, 428-9(1915).—The object of the paper, illustrated by 14 photomicrographs, "is not to place in respect of suitability any one class of aggregate material mentioned above another," but "rather to urge the need of careful selection and grading of the aggregate."

W. D. COLLINS.

Preserving wood. O. P. M. GOSS. U. S., 1,167,492, Jan. 11. Wood is immersed in preservative liquid and heated to 110° , then the preservative is drawn off and the wood is subjected to a vacuum of 23-28 in. while heated for 30 min. The vacuum is broken and preservative liquid reintroduced into the treatment chamber and allowed to act with heat and pressure for 1-6 hrs. It is then withdrawn and the wood is again subjected to a vacuum while still hot, to remove surplus liquid.

Impregnating wood. R. LAMB. U. S., 1,168,944, Jan. 18. Wood is treated with steam under pressure and while still under this steam treatment the impregnating liquid is forced in contact with the wood, under greater pressure than that of the steam. The unabsorbed liquid is then withdrawn from the treatment chamber so that the steam expels excess liquid from the wood on release of the pressure.

Making cement and sulfur dioxide. L. P. BASSETT. U. S., 1,168,046, Jan. 11. A mixt. of clay, $CaSO_4$, and coal is heated in a furnace to form cement and air is injected into the furnace at a point where the temp. is about 900° to oxidize the gases to CO_2 and SO_2 , the latter being recovered as a by-product. Cf. C. A. 9, 365.

The development in the United States of the manufacture of products derived from coal. H. W. JORDAN. *J. Ind. Eng. Chem.* 8, 172-4(1916); *Chem. Eng.* 23, 56-9(1916).—An address. E. J. C.

Naphthalene and its applications as a fuel for explosion engines. K. BRUHN, Essen. *J. Gasbel.* 58, 579-82, 592-5(1915).—A general review covering types of engines, details of design, test data, and costs. W. L. BADGER.

Smoke problems. KONRAD W. JURISCH. *Chem. Ztg.* 40, 25-6(1916).—Comments on problems resulting from substituting lignite and briquets for coke. J. H. MOORE.

Substitution of heating value for candle power as a standard of gas quality. R. S. McBRIDE. *Am. Gas Light J.* 104, 99-103(1916); see *C. A.* 10, 112. E. J. C.

Sampling and analyzing flue gases. H. KREISINGER AND F. K. OVTZ. U. S. Dept. Interior, Bur. Mines, *Bull.* 97, 64 pp.(1915).—The collection of flue gases with open-end and perforated tube samplers, and the analysis of the gases with the Orsat app. is described in great detail, followed by a discussion of the application of flue gas analysis in reducing boiler room losses. K. and O. find that for water tube boilers, the open-end sampler placed in the center of the cross-section of the boiler uptake, gives satisfactory samples. With fire tube boilers, the perforated tube sampler is necessary for the collection of av. samples. When the flue gas is collected in sample bottles satd. brine should be used instead of water, the gas should not be bubbled through the brine, the shaking of gas and liquid must be avoided, and the gas analyzed as rapidly as possible after collection. E. A. TSCHUDY.

The determination of benzole in gas. C. NEUBECK. *J. Gasbel.* 58, 616-7(1915).—Absorption in paraffin oil followed by distn. of the oil at 120° gave good checks when known amts. of benzole were evapd. into a current of air and absorbed (24 g. taken, 22.5 found; 12 g. taken, 11.35 found). There is so much difficulty in keeping rubber stoppers and joints tight during distn. that the method is not recommended. A modification of the "Claire Deville" method is described and recommended. The inlet tube of the condensing spiral is considerably enlarged to prevent stoppages. On the exit end of the coil is a small wash-flask containing paraffin oil. Flask and coil are weighed and then placed in a Dewar flask covered with felt. The coil is packed in CO₂-ether mixt., a CaCl₂ tube being attached to the inlet during cooling. The Dewar flask is closed by a loose cork with an alc. thermometer; the temp. should be -78°. Up to 400 l. of gas are passed through with a velocity which may be as high as 50 l. per hr. The coil is removed, carefully freed from the freezing mixt., allowed to warm up to room temp., and weighed. 4.6 g. benzole evapd. into a current of air gave 4.70 recovered; 8.136 g. in 108 l. air gave 8.15 recovered. W. L. BADGER.

Gaseous viscosity. I. T. HOLGATE. *Gas World* 63, 266-7(1915).—A discussion of the general principles relating to gaseous viscosity preparatory to an exposition of its practical applications. II. *Ibid* 293-5.—H. gives the following formula for expressing the viscosity of a gas as a function of the temp.: $\mu = KT^{1/2}/1 + C/T$ where μ = abs. viscosity, T = abs. temp., and K and C are consts. characteristic of each gas. Knowing K and C for air, H, CO and C₂H₄, H. calculates the viscosity of each gas at temps. from 0° to 1752°. Air and CO increase in viscosity to about the same extent by increasing the temp. from 0 to 1752°; H less, and C₂H₄ more. The best values for the abs. viscosity of the common gases at 0° are tabulated. Thus from the analysis of a sample of any gas, the viscosity at 0° can be roughly calcd., and the influence of change in compn. upon the viscosity can be predicted. Practical applications of viscosity relationships in technical problems can be made to (1) the resistance to flow—
ough distributing pipes as a function of the compn. of the gas and (2)

the change in adjustment of gas and air necessary in a recuperative inverted burner after heating up, and the part that changes in viscosity of the constituent gases with temp. play in this phenomenon.

F. L. GROVER.

The influence of water vapor on the yield of ammonia in the decomposition of solid fuels in gas producers. KURT P. SACHS. *Stahl u. Eisen* 35, 801-10(1915).—The expts. were conducted in lab. app., and a gas producer using coke, anthracite coal, and lignite. The lab. tests showed that with a small quantity of water vapor 900° was the most favorable temp. while with much vapor 800° was better. Furthermore, with increasing moisture content in the blast the NH_3 production increased. The results were greatly improved by passing the gas through tubes which caused its sudden chilling. This method of treatment showed more satisfactory results when the temp. was high and the amt. of water vapor low. The tests showed that it is possible to recover all the N of the fuel in the form of NH_3 . The use of the cooling tubes is an important factor and may cause this process to supersede the Mond process.

CARLE R. HAYWARD.

New apparatus for the manufacture of ammonium hydroxide from raw gas liquor. R. W. HILGENSTOCK. Düsseldorf. *J. Gasbel.* 58, 709-14(1915); *Am. Gas Light J.* 103, 241-3(1915).—The raw liquor goes to a const.-level regulator (1) and then to a short column (2) in the lower sections of which the liquor is heated to 98-100°. This decomposes carbonates and sulfides; the CO_2 and H_2S rise through the upper sections, are washed with H_2O to remove NH_3 , and finally escape. Vacuum formation in the app. is prevented by 3 which admits air if less than atm. pressure is produced.

The liquid residue goes to the free NH_3 still (4a), and from this, after mixing with CaO , to the fixed NH_3 still (4b). The NH_3 vapors from (4b) are returned to (4a), and from (4a) they pass to a reflux condenser (5) where they are freed from steam, and then to a H_2O washer (6), and a NaOH washer (7). In 6 enough H_2O is used to give only sufficient cold satd. soln. to dissolve most of the CO_2 and H_2S remaining. In most cases the amt. of H_2O may be so regulated as to give a pure NH_3 gas. The soln. of CO_2 and H_2S is returned to 2 so that no loss of NH_3 takes place. The gas is finally washed with a very small amt. of NaOH soln. in 7 and then passes to an oil washer (8) where tars and empyreumatic substances are removed. If commercial NH_4OH is de-

sired, the gas goes from 8 to a saturator (9) fed with condensed H_2O from the heating coils of 2. If c. p. NH_4OH is to be made the gas is filtered through charcoal and then bone-black after 8 and then sent to 9. Advantages claimed are a pure product, the use of a minimum amt. of $NaOH$ and CaO , and the avoidance of an alk. waste containing S and pyridine to be disposed of, as CO_2 , H_2S , pyridine, etc., are discharged as gases. Estimates for a plant to work up 100 cu. m. gas liquor of 2% NH_3 per 24 hrs. are: cost of building, \$9500; of app., \$14,300; for every cu. m. of gas liquor 275 kg. steam and 2 cu. m. cooling H_2O ; for every kg. NH_3 worked up 0.7 kg. CaO , 10–15 g. of 70% $NaOH$ soln., 10–20 g. oil for washers, 0.1 c. for bone-black; 3 men on each 12-hour shift. W. L. B.

Naphthalene and gas washing. T. GLOVER. *J. Gas Lighting* 132, 581–2(1915).—In working the "C" process the $C_{10}H_8$ content of gas is dependent on 3 factors: (1) the $C_{10}H_8$ content of tar used as a washing medium. This in turn depends on the conditions of coal carbonization. Small charges with high heat produce high $C_{10}H_8$ and tar. (2) Proportion of light hydrocarbon vapors to the vapors of $C_{10}H_8$ present in gaseous carbonization products. The light vapors are first produced by incomplete decompn., and as a secondary product, $C_{10}H_8$ is formed by exposure to hot surface and radiant heat. (3) Temp. of washing. The capacity of tar to absorb $C_{10}H_8$ and naphthas increases as temp. diminishes. All trouble with $C_{10}H_8$ is avoided by using a heavy charge in the coking oven for a 12-hr. period; also the production of light oils is at a max. It is suggested, if small charges must be used, to introduce naphtha vapors of approx. the same vapor tension as $C_{10}H_8$ at whatever point $C_{10}H_8$ deposits are giving trouble. An alternative is the use of vaporized petroleum. R. H. S.

Petroleum vaporized for preventing naphthalene deposits. ANON. *J. Gas Lighting* 132, 582(1915).—Extn. of C_6H_6 , $CH_3C_6H_5$, etc., from the gas removes the natural solvent for $C_{10}H_8$ and hence the latter is deposited. The obvious remedy is to replenish the solvent. For this purpose the gas is passed through a carburetor fitted with a high-pressure steam coil on which petroleum oil is dropped from a distributor, and vaporized. This not only furnishes the necessary solvent but slightly enriches the gas. In case the gas accidentally becomes low in value it can be greatly enriched by using petrol or C_6H_6 in the app. Under av. conditions it has been found that 25 gals. of petroleum will deal satisfactorily with 1,000,000 cu. ft. of gas. R. H. SAWENS.

Evaporation of naphthalene in coal gas. J. S. G. THOMAS. *Gas World* 63, 644–7(1915); *J. Gas Lighting* 132, 701–3(1915).—The vapor pressure of $C_{10}H_8$ was detd. by a method of evapn. as follows: first a sample described as "pure" was further treated alternately with H_2SO_4 and KOH , then 3 times steam-distd., sublimed, and finally dried *in vacuo*. The gas (either air or coal gas), thoroughly dried by passage through H_2SO_4 and $CaCl_2$ tubes, was brought to the temp. desired by passage through a long glass tube immersed in a const. temp. H_2O bath. From there it passed through another $CaCl_2$ tube and 2 tubes of weighed $C_{10}H_8$, all three of which were enclosed in a water-tight metal jacket immersed in the water bath. A H_2SO_4 bottle to remove the $C_{10}H_8$ from the satd. gas and an aspirator completed the app. After passing through a measured quantity of gas the $C_{10}H_8$ was reweighed, and from the loss, its vapor pressure calcd. Coal gas and air gave concordant results. T. observes that his results agree with those of Schlumberger throughout, but that Allen gives much higher figures for temps. between 0° and 30° . Suggestions as to the possible cause of this discrepancy are given. A comparison with results calcd. from an empirical formula shows very close agreement. Tables and curves giving values at from 0° to 60° are given.

R. H. SAWENS.

Distillation of gas liquor without lime. J. S. UNGER. *Gas Age* 36, 301(1915); *J. Gas Lighting* 132, 144(1915).—The still described recovers the free NH_3 , and is so arranged that a "lime leg" and additional sections may be added when it is desired to

recover the total NH_3 . The essential feature is a heating arrangement at the top which brings the weak liquor to about 190° before entering the still proper, the liberated gases being washed by coal liquor passing through a washer. This absorbs the NH_3 and allows the gases to escape, making possible a concentrate of 20% NH_3 without the use of lime.

R. H. SAWENS.

The economy of the "combined oven" for gas works. SCHADECK. *J. Gasbel.* 58, 543-9(1915).—A discussion of the Koppers oven as arranged for firing with either coal or producer gas. It would be economical if the price of coke were 16 to 20% higher than coal, depending on the value of by-products. The important advantages of the combined oven over a standard by-product oven are: (1) The entire plant may be kept in full operation the year round, as one oven at a time may be shifted from coal to producer gas or *vice versa*. All ovens operating on coal gas will give a yield of salable gas of 55 to 60% of the yield when using producer gas, and if the demand is very low the time of coking can be lengthened to give about 30% of the max. output. The result is greatly increased life of the ovens. (2) The production of gas can be made to correspond exactly to the demand. (3) When the demand for gas is low, by firing with coal gas 10 to 13% more coke is available for sale. (4) Since the ovens may be shifted one at a time and the whole plant is always in operation, division into blocks is unnecessary, making construction cheaper. Drawings are given showing the different modes of operation and a comparison is made between chamber oven plants and combined ovens. On the basis of a max. daily output of 3,530,000 cu. ft. the combined oven saves \$4.91 per oven per day.

W. L. BADGER.

Australian experience of Glover-West vertical retorts. J. MACKENZIE. *Gas World* 64, 37(1916).—M. gives a detailed description of experience in operation of these retorts. The advantages found are stated as (1) large saving in labor; (2) increased yield of gas; (3) great improvement in working conditions, but the coke is different, being harder and having all volatile matter removed, and this tar is much thinner and contains more light oil.

M. L. TROWBRIDGE.

Efficacy of Carpenters reversible condenser. T. O. MORLAND. *Gas World* 64, 38(1916).—A description of the app. is given. H_2O can be used on the condenser if desired, but cooling by this method was found to be unnecessary; the temp. of the atm., if the app. is not overworked, has been sufficient to produce satisfactory results. When in use any C_{10}H_8 which the gas may contain is lodged in the pipes through which it rises, and when the current is reversed the hot hydrocarbon vapors dissolve and carry with them to the tar tank any C_{10}H_8 adhering to the sides of the condenser. The current is reversed twice weekly. It is important that ample condensing surface be provided, 12 to 15 sq. ft. per 1000 cu. ft. of gas per day is recommended.

M. L. TROWBRIDGE.

Distillation of tar in gas works. A. P. BRUIGON. *J. Gas Lighting* 133, 34-5 (1916).—B. suggests some of the disadvantages of the old-fashioned intermittent tar still and describes a more efficient up-to-date plant. After the crude tar is preheated it flows continuously in a thin jet into a column still passing downward over coke or other filling material. The oils are vaporized by a jet of superheated steam introduced in an upward direction. The striking advantage of superheated steam is shown by an expt. in which equal quantities of 3 oils boiling at 200, 300 and 400° , resp., were distd. over at 100° and atm. pressure by quantities of steam proportional to 1:8:60; while with superheated steam at 200° these proportions became 1:1.6:2.4. The distn. is carried out by degrees so that the vapors are immediately sepd. from the remaining liquor. Inasmuch as no low-boiling vapors are present in the bottom part of the still the hot liquor leaving the column is nothing more than molten pitch. Soft pitch may be obtained with sufficient sepn. of the fractions for gas-works purposes.

Suggestions for a building and plant with cost estimate to handle annually 1500 metric tons of tar are given. R. H. SAWENS.

Changes in hydrocarbons at high temperatures, and formation of coal tar. J. P. WIBAUT. *Chem. Weekblad* 12, 954-66(1915).—A report of a lecture, mainly dealing with the literature of the above subject. J. T. FLOHL.

Process for the preparation of carbolic oil. F. RASCHIG. *Z. angew. Chem.* 28, I, 409-12(1915).—The German "middle oil" (fraction from 170-250°, d. 1.0-1.02) from tar distn. is relatively poor in phenol and the prepn. of a carbolic oil rich in phenol is an essential preliminary to the NaOH extn. R. accomplishes this by fractional distn. of the middle oil *in vacuo*, using a still of 5-20 cu. m. capacity (heated with steam under 6-8 atms. pressure) connected by a wide, slightly inclined still-head to the base of a column 14 m. high and 60 cm. diam. filled with R.'s patented rings, and provided with a reflux tube at the bottom leading back into the still. The column is surmounted by a dephlegmator leading to a worm condenser, from which a vertical exit pipe at least 12 m. long to overcome, when full, the atm. pressure, discharges the distillate into the open air under normal pressure, and it can thus be sampled from time to time as desired. The condensing H₂O passes first through the condenser, then through the dephlegmator, and the distn. conducted so that about 4 times as much vapor condenses in the latter as in the former. Under these conditions, with a column of the height specified, a fraction (solvent naphtha II) free from phenol is first obtained, and then, by a fairly sudden transition, carbolic oil passes over containing 30-40% of phenol. The phenol content finally falls to 20-25% and the distillate on cooling to about 15° deposits naphthalene; the distn. is stopped at this point, and the residue in the still is run into a cooling bath to crystallize. With the same plant a considerable carbolic oil fraction can be obtained from "light oil," and at the same time commercial C₆H₆ and toluene are obtained of better quality than by the usual methods, and quite free from phenol. F. W. SMITHER.

Thermal reactions in vapor phase of various coal tar oils and distillates. W. F. RITTMAN AND G. EGLOFF. *Met. Chem. Eng.* 14, 15-8(1916).—Several coal-tar oils and distillates, all of the class less valuable commercially, such as solvent naphtha, creosote oil, light dead oil, etc., were subjected to cracking by heating to temps. from 600 to 700° under pressures from 1 to 15 atms. The percentage recovery of benzene and toluene was somewhat larger than that when petroleum was similarly cracked. In general from 20 to 40% of the 200° cut from the original oil was recovered as benzene and toluene. Oils or fractions of oils boiling above 200° were not converted into the simple aromatics. R. believes interaromatic reactions take place in the following sequence: higher benzene homologs, lower benzene homologs, benzene, naphthalene, anthracene, etc. F. L. GROVER.

Coal tar and its products. ANON. *Eng. Mining J.* 101, 7-8.—A schematic presentation of the subject showing interrelationships and yields. F. L. GROVER.

Effect of aeration and "watering out" on sulfur content of coke. J. R. CAMPBELL. *Bull. Am. Inst. Mining Eng.* 1916, 177-80.—S is known to exist in coal as sulfides and sulfates and as so-called organic S. For most coking coals it is in the form of pyrite (FeS₂). Exposed to comparatively low temp. during coking about 42% is volatilized; the rest remains as pyrrhotite. In beehive practice the air oxidizes the S to SO₂, then to SO₃, which forms H₂SO₄ as it comes in contact with moisture; that remaining as FeS can not in any way be affected by aeration or draft on the oven. In the by-product oven the S is distd. as atomic S but apparently, it afterwards combines with the H of the coal gas and forms H₂S. Any organic S remains for the most part in the coke and would be unaffected by aeration except in event of total destruction of C with which it is combined. Sulfates present as CaSO₄ would be unaffected by aeration or

superaeration. When coke is quenched externally, the action of the H_2O on the FeS is as follows: $FeS + H_2O = FeO + H_2S$. The same holds true in quenching in the oven itself as in beehive practice. H_2S is evolved; also the steam is decomposed by the C. From experience it is concluded that only an infinitesimal percentage of S is given off during the quenching process. It is stated that the addition of HCl to the H_2O will greatly facilitate the removal of S.

M. L. T.

Chemical and geological distinction of coal from lignite (SACHS) 8.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

The effect of temperature on the formation of benzene, toluene, xylene, naphthalene and anthracene from petroleum at atmospheric pressure. G. EGLOFF AND T. J. TWOMBLY. *J. Phys. Chem.* 20, 121-50(1916).—The object of the authors was to det. the effect of temp. on the formation of C_6H_6 , C_7H_8 , C_8H_{10} , $C_{10}H_8$, $C_{14}H_{10}$ from petroleum with all factors kept constant. A thorough historical review of the work done upon the cracking of petroleum for aromatic hydrocarbons is given. The app. consisted of an elec. heated furnace, a condenser and a receiver. The oil was fed through the furnace at a definite rate, and after the run was completed, the cracked oil was tapped from the condenser and weighed, and the vol. of gas produced noted in the gasometer. In each expt. 574 g. were passed through the furnace at the rate of 246 g. per hr. The temps. employed ranged from 450 to 875°. The oil used was a gas-oil distillate made from Penn. crude petroleum, possessed a sp. gr. of 0.817, and when distd. yielded 2% up to 200°, 7.3% between 200 and 250°, 57.0% between 250 and 300°, 28% between 300 and 350°, and 5.5% residue. The cracked oil as it came from the condenser was found to contain appreciable amts. of C, which had to be removed by filtration. The oil was analyzed by distn. The fraction boiling below 170° was examd. for C_6H_6 , C_7H_8 , C_8H_{10} . The fraction boiling above 170° was redistd., and fractions between 170 and 230°, 230 and 270°, and 270° and tar were sepd. The $C_{10}H_8$ and $C_{14}H_{10}$ were obtained from these fractions by chilling in ice-salt mixt., and pressing and drying solid aromatics with filter paper. The sp. gr. of the distillate to 170° detd. the percentages of C_6H_6 , C_7H_8 and C_8H_{10} . The following effects were noted: The per cent. of cracked oil decreased with increase in temp. At 450°, 97.4% of recovered oil was obtained; at 500°, 84.9%; at 600°, 62.8%; at 700°, 26.7%; at 800°, 20.7%; at 875°, 9.4%. The gas formation increased with temp.; the sp. gr. of the cracked oil also increased with temp. At 450 to 600°, more C_7H_8 and C_8H_{10} than C_6H_6 were produced, and more C_7H_8 than C_8H_{10} . No naphthalene nor anthracene were found at these temps. At 650°, more C_7H_8 than C_6H_6 were obtained, but more C_6H_6 than C_8H_{10} . At 700 to 875°, more C_6H_6 than either C_7H_8 or C_8H_{10} were formed. Naphthalene formation began at 750°, anthracene at 800°. The max. of C_6H_6 formation in the cracked oil was 21.0% at 800°; the max. of C_7H_8 was 8.3% at 700°, and C_8H_{10} 7.2% at 700°. The largest % of naphthalene was 11.4% at 875°, and anthracene 2.5% at 875°. From 450 to 700° mixts. of aliphatic and aromatic hydrocarbons were obtained; above 700° no aliphatics were left in the cracked oil. On the basis of the oil used 4.6% of C_6H_6 were produced at 750°, 3.1% of C_7H_8 at 650°, 1.9% C_8H_{10} at 700°, 2.0% of naphthalene at 800°, and 0.3% anthracene at 800°. The aromatic formation is as follows: higher homologs form C_7H_8 and C_8H_{10} , which go to C_6H_6 , which is transformed to naphthalene, and then to anthracene.

O. E. BRANSKY.

Distillation of mineral oils and liquid hydrocarbons, fatty acids, and similar products. L. SINGAR. *Petroleum* 10, 605-8(1915).—The advantages of high vacuum

distn. are pointed out. Better lubricating oils, paraffin wax, and asphaltic products are obtained by this method, while the loss as fixed gas, the amt. of fuel, and the time of completing a distn. is considerably decreased. The products are homogeneous in compn., and require less chem. treatment for purification. O. E. BRANSKY.

The Hellige petroleum colorimeter, and transposition numbers for this and the Stammer and Wilson colorimeter. L. UBBELOHDE. *Petroleum* 10, 725-8(1915).—A new app. for which accuracy and ease of manipulation are claimed. A soln. of 0.06 g. of $K_2Cr_2O_7$ in 1 liter of H_2O is used as the standard color. By means of the formula $S = 3733.5/H$, in which S is the Stammer no. and H , the Hellige no., the 2 values are correlated. By means of a curve, the values of the Hellige, Stammer, and Wilson can be readily interchanged. O. E. BRANSKY.

The Uralsk province and its oil fields. F. A. HOLIDAY. *J. Roy. Soc. Arts* 64, 158-66(1916).—The Uralsk province, situated along the Caspian Sea and the Emba river, has an area of 27,250 sq. miles. Considerable oil has been found, and many wells are flowing. One gusher, struck at a depth of 732 ft., has produced to date over 140,000 tons. The oil is green, has a sp. gr. of 0.861, and yields 0.36% of gasoline, 23.66% kerosene and 74.92% residues. O. E. BRANSKY.

Cracking and distilling petroleum. W. M. BURTON. U. S., 1,167,884, Jan. 11. Petroleum having a b. p. above 260° is distd. at a temp. of $340-450^\circ$ under a pressure of 3 atm. or more until about 65% of the oil has been distd. The residue is withdrawn from the pressure still, and distd. under approx. atm. pressure. A product is obtained having a d. of 15° Bé. and a viscosity of about 130° Saybolt at a temp. of 38° .

Catalyst for cracking petroleum oils. O. D. LUCAS. U. S., 1,168,404, Jan. 18. A mixt. of oxides and oxalates of Fe and Ni, Cr or Co is heated to a sintering temp. with small amts. of C and Al, Mg or Ce to reduce the metallic compds. The metallic catalyst thus formed retains its efficiency in continued use for cracking oils, for a considerable time.

Paraffin emulsion. G. W. MILES. U. S., 1,168,534, Jan. 18. Paraffin is heated with soap and H_2O to form a viscous paste and this is subsequently thinned by adding H_2O .

Solidifying tar oils. L. BEREND. U. S., 1,167,373, Jan. 11. Mineral oil, tar oil, asphalt, waxes, resins, etc., in the form of liquid mixts., are emulsified with sulfite cellulose waste liquor and a solid mixt. suitable for use in fuel or road material is produced by the addition of a filler such as wood flour, coal or peat and sufficient CaO to combine with the H_2O present.

Alcohol; petrol. C. TUCKFIELD and W. G. DE F. GARLAND. Brit., 19,845, Sept. 16, 1914. Alc., naphtha, petrol, and other spirits are sepd. from solns., mixts., etc., by heating under pressure, preferably to $300-500^\circ F.$, and then decanting the sepd. upper layer of spirit. A suitable app. is specified.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Fiber length of cellulose. ERICH RICHTER. *Wochenbl. Papierfabr.* 1915; *Paper* 17, 17-9(1915).—Lengths of unbroken fibers of sulfite cellulose of American, German and Scandinavian origin varied from 0.081 to 0.118 in., the av. being 0.098 in. The proportion of fibers whose length was equal to the av. length of the unbroken fibers varied from 47 to 74% of the whole, the proportion being less in case of American

pulps, most of which are made by the quick-cook process and are blown from the digester. Lignin content of the pulps varied from 2.9 to 9.3%. V. NUNEZ.

Paper industry and substitute materials. U. HAASE. *Kunststoffe* 6, 10-1 (1916).—A brief review of the manufacture of pasteboard and crepe paper and the various uses that have been suggested for them, e. g., substitutes for cigar box wood, textile wares, etc. F. W. SMITHER.

A process for making paper without sulfite. ALBERT KEMP. *Paper Trade J.* 62, No. 1, 46-8 (1916).—The process consists in boiling wood under steam and water pressure in closed vessels, air being excluded. A pulp is produced by grinding, from which news, book and other grades can be made without any addition of sulfite. The process also renders rosin sizing unnecessary, as the rosin in the wood suffices for the purpose. E. J. KELLEY.

Tar size. EMIL HAUSER AND WERNER SCHMIDT. *Papier-Ztg.* 40, 1800 (1915).—A size for paper, prepd. from beechwood tar saponified by alkali, has been found to be an effective size for paper. Used alone, it is not retained by the pulp, but when mixed with a small percentage of rosin soap, excellent results are obtained. Pptn. is by alum or NaHSO_4 in the usual manner. The dark color of the size prevents its use in white paper. V. NUNEZ.

Adsorption of caustic soda by cellulose (LEIGHTON) 25.

Apparatus for cooking wood-pulp. L. B. DECKER. U. S., 1,167,800, Jan. 11.

Apparatus for bleaching paper pulp. F. G. TEN BROECK. U. S., 1,167,728, Jan. 11.

Flax-straw paper. F. H. COYNE. U. S., 1,168,285, Jan. 18. Flax straw is treated in a beater until reduced to paper pulp leaving the cortex in small unreduced fragments which are used in making paper, together with the reduced portions. The paper is especially intended for use with roofing compositions.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Properties and uses of military explosives. LOGAN CRESAP. *Iron Age* 96, 752-3 (1915).—Nitroglycerin smokeless powder is styled in different countries ballistite, filite, solenite or cordite. In British m. d. cordite there is 65% nitrocellulose, 30% nitroglycerin and 5% vaseline, but other varieties of this class of smokeless powders contain as high as 58% of nitroglycerin. The U. S., France, Russia and Spain use nitrocellulose powders in all guns. Great Britain and Italy use nitroglycerin powders in practically all guns. The other powers use nitrocellulose powders for small arms and nitroglycerin powders for larger guns. Since the great war began some modification has taken place, owing to the consumption of U. S. powders which are practically all nitrocellulose. Ammonium picrate is used in shells in place of picric acid. In the U. S. this bursting charge is styled dunnite, in Italy pertite, in Spain picrinite, and in Sweden coronite. Trinitrotoluene when mixed with $\text{Pb}(\text{NO}_3)_2$ is styled macarite. Ammonal (NH_4NO_3 85, Al 10 and C 5%) has been used to a limited extent in Austria as a bursting charge for shell. Sometimes 15% of trinitrotoluene has been mixed with it. CHARLES E. MUNROE.

Primer for explosives. W. RUNGE. U. S., 1,168,746, Jan. 18. Pb azide is mixed with 5-30% its wt. of trinitrotoluene, with or without a very small amt. of gum

arabic as a binder. The mixt. gives a more effective detonation than a mixt. of Pb azide and a chlorate.

Acetylating nitrocellulose. L. CLEMENT and C. RIVIERE. U. S., 1,168,164, Jan. 11. A mixt. of Ac_2O with HOAc and H_2SO_4 or $\text{C}_6\text{H}_5\text{SO}_3\text{H}$ is used to react upon a lower nitro deriv. of cellulose which is insol. in organic acids, Ac_2O , HCl , HNO_3 , phenols, alk. hydroxides, alc.-ether and acetone, and the resulting acetylated product may then be hydrolyzed.

Picric acid. G. B. BRADSHAW. U. S., 1,168,266, Jan. 11. Phenol is sulfonated and the product is converted completely into *p*-phenolsulfonic acid by dilg. with H_2O to 30°Bé. and boiling with live steam or by heating with excess H_2SO_4 to 127° . The resulting soln. is nitrated with about 3.5 times its wt. of HNO_3 of 40°Bé. and heated to 90° to complete the nitration. A better yield of picric acid is obtained than in usual similar processes by reason of the complete conversion of the sulfonic acids into the *p*-acid.

Match splints. J. R. NOLAN. U. S., 1,168,901, Jan. 18. Wood match splints are coated with a finely powdered mixt. of alum and paraffin or H_3BO_3 and paraffin and then heated to fuse the paraffin and effect impregnation of the splints to render them readily combustible but non-glowing when extinguished.

Match splints. W. A. FAIRBURN. U. S., 1,168,869, Jan. 18. Wood match splints are rendered readily combustible but "non-glowing" when extinguished by impregnation with a mixt. formed of molten paraffin mixed with vaseline in which H_3BO_3 or other "anti-glowing material" has been incorporated. Cf. C. A. 9, 2815.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Dyestuff situation in the United States at the close of 1915. THOMAS H. NORTON. *J. Ind. Eng. Chem.* 8, 166-72 (1916).—An address. E. J. C.

Quantitative estimation of alizarin and of certain other dyestuffs. EDMUND KNIGHT AND EVA HIBBERT. *J. Soc. Dyers Colourists* 31, 241-4 (1915).—The method is based upon titration of dyestuffs in alc. soln. with TiCl_3 . An excess of standard TiCl_3 soln. together with a 20% soln. of Rochelle salt is added to an alc. soln. of the dyestuff and boiled, the excess of TiCl_3 being detd. directly by titration with iron alum soln. The method is considered in connection with alizarin, anthrapurpurin, flavo-purpurin, alizarin black and gallocyanine. L. A. OLNEY.

The interaction between metallic copper and certain dyes of the thiazine, oxazine and azine series. J. R. HANNAY. *J. Soc. Dyers Colourists* 31, 244-52 (1915).—Solns. of methylene blue of different brands in 30% AcOH have a decided action on Cu while AcOH without the blue has no action. When Cu is boiled with such solns. of methylene blue and AcOH it loses weight rapidly and a greenish blue, semi-cryst. material is obtained which, when made up into a printing paste, had but little coloring power as compared with the org. dyestuff. The same was found to be true of Nile Blue A, Safranin FF, Methylene Violet R R A. Acridine Orange N O a dyestuff somewhat removed in constitution from the others also showed a solvent action on copper. On the other hand Rhodamine 6 G and Brilliant Green and Thioflavine T gave no indication whatever of action on Cu. No theory giving any reasonable explanation of the results has as yet been formulated. H. finds speck and flat prints which result when Methylene Blue is dissolved in copper vessels is entirely overcome when the soln. is made in porcelain. L. A. OLNEY.

Dye lakes and filled dyes. WILHELM OSTWALD. Grossbothen. *Kolloid-Z.* 17, 65-78(1915).—Instead of a dye lake in which the colloidal dye is pptd. by another colloid, usually alumina, using an excess of the alumina to dilute the color if that is desired, there are advantages in using a "filled dye" in which a second material, very finely ground and either cryst. or amorphous, is used to dilute the dye lake which contains only enough alumina for complete pptn. of the dye. Such a filled dye gives a brightness nearly inversely proportional to the log of the concn. of the dye if a white filler is used. As filling material ground heavy spar gives the deepest color for a given dye content but cannot be used with an oil binding agent because of its poor covering properties. The brightness of 0.25% methyl violet in various fillers and 4% lime as binding agent varies as follows (white light = 1000): Ground heavyspar 99, pptd. CaCO_3 121, ground gypsum 143, burned gypsum 158, heavyspar and kaolin 3:1 194, CaCO_3 pptd. light 206, lead white 213, BaSO_4 pptd. moist 216, kaolin 225, chalk 226, BaSO_4 pptd. dried 239, lithopone 322, zinc white 330, MgCO_3 349. The covering power is about $1/12$ as great with heavy spar as with MgCO_3 because of the greater size of the particles of the heavy spar. The effect of the filler on the brightness of the filled dye seems to depend mainly on the size of the particles of the filler—the smaller the particles the brighter is the filled dye, and the greater its covering power. Microphotographs show that the fillers show decreasing size of particle in the same order that they show increasing brightness. The color of the filled dye varies somewhat with the various fillers. An oil emulsion known as Tempera added to a lime binding agent increases the depth of color considerably.

H. I. MATTIL.

The black dyeing of furs with hints on other colors. "Cosmos." *Leather Manufac.* 27, 1, 13-5(1916).—To prevent injury to the leather dyeing is done at low temp. Many furs have a fine wooly coat next the skin, and a number of longer hairs. The latter are harder to dye and require softening. For best results artificial heat should not be used in drying. Recipes are given for the application of a number of dyes upon leather.

J. S. ROGERS.

Weighting of silk as a chemical reaction. F. FICHTER. *Naturfors. Ges. Basel*, June 16, 1915; *J. Soc. Chem. Ind.* 34, 1008.—The weighting of silk by means of SnCl_4 is due to the formation and progressive hydrolysis of an addition compd. of the Sn salt with the silk fibroin (cf. *C. A.* 8, 3630). In the subsequent treatment with phosphate, the silk fiber plays no part, the sole reaction being between the stannic acid and H_3PO_4 or Na_2HPO_4 .

L. W. RIGGS.

Adsorption of caustic soda by cellulose. ALAN LEIGHTON. *J. Phys. Chem.* 20, 32-50(1916).—Most, and perhaps all, of the adhering liquid may be removed from cotton by centrifuging for an hour at 4000 r. p. m. An analysis of the cotton gives the amt. of NaOH adsorbed, subject to a correction for any failure to get the cotton dry. Data obtained in this way gave a smooth adsorption curve. There is no evidence of the formation of a compd. when cotton is treated with NaOH for concns. up to 500 g. NaOH per l. Mercerization of cotton is not due to the formation of any compd. of cellulose and NaOH. Until the amt. of adsorbed NaOH is 0.34 g. per g. of cotton there is apparently no displacement of H_2O from the cotton, but there is a decrease in the amt. of H_2O adsorbed for amts. of NaOH higher than this. A standard and reproducible cellulose may be obtained by heating absorbent cotton with 1% NaOH for 18 hrs. on the water bath.

E. B. MILLARD.

β -Chloro derivatives of anthraquinone. FARBW. v. M. L. & B. Ger., 284,976. Nov. 19, 1913. Instead of 1-anthraquinonesulfonic acid, which is recommended in 267,544 (*C. A.* 8, 1018), anthraquinone- β -sulfonyl chloride is heated with SOCl_2 to a high temp. (220°).

N-Anthraquinonylisatins. BAYER & Co. Ger., 285,771, Apr. 7, 1914. Addition to 236,407 (C. A. 6, 1230). The parent process is modified by discontinuing the action of the halogenated anthraquinones or their derivs. on isatin, its homologs or analogs, before the formation of the vat-dyeing anthraquinone acridones results, or by removing the anthraquinone acridones from the reaction mixt. by suitable methods. Cf. C. A. 9, 2598.

Octochloro- and decachloroanthracene. FARBW. v. M. L. & B. Ger., 284,790, Dec. 24, 1913. These products are obtained by chlorinating anthracene or 9,10-dichloroanthracene in the presence of I, in CCl_4 . The reaction products are sepd. according to their different soly.

Compounds of basic dyes of the acridine and safranin series. BAYER & Co. Ger., 285,500, Feb. 7, 1915. These products are obtained by converting the dyes of this series, or their salts, according to the usual salt-forming methods, into their gallocarboxylic acid salts.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Alizarin red (madder) and geranium lacquers. ANON. *Farben-Ztg.* 21, 230-2 (1915).—A general descriptive article. E. W. BOUGHTON.

A case of fatal poisoning due to spraying in a varnish department. R. P. ALPAUGH. *Ohio Pub. Health J.* 6, 512-4 (1915).—The symptoms present in a case of supposed naphtha poisoning are described. The physiological standards of endurance of benzine, benzole, and turpentine, which are used either separately or together in this kind of work, have been detd. *Benzine* (naphtha, gasoline, pet.-ether) 0.02 g. per l. of air will cause local symptoms, while 0.05 g. per l. of air is poisonous. *Benzole* 0.015 g. per l. of air is poisonous, while 0.042 g. per l. will kill dogs in 20 min. *Turpentine* 0.003 g. per l. of air cause local symptoms, while 0.006 g. per l. poisons a healthy man in from 1 to 4 hrs. J. GAUB.

Paint. S. LOWY. U. S., 1,168,730, Jan. 18. A mixt. of shellac 5 lbs., NaOH 4 oz., borax 6 oz., ZnSO_4 2 drams and H_2O 10 gals. is added to Pb paint in equal proportions to decrease its cost.

Lead chromate. A. S. RAMAGE. U. S., 1,168,417, Jan. 18. Pb or galena is dissolved in HNO_3 or HOAc, the Pb is pptd. as PbSO_4 by adding H_2SO_4 and the ppt. is washed and digested with $\text{Na}_2\text{Cr}_2\text{O}_7$ and NaOH. The acid soln. formed on pptn. with H_2SO_4 is used to dissolve fresh portions of Pb or galena.

Lead sulfate. A. S. RAMAGE. U. S., 1,168,418, Jan. 18. Galena is roasted with limited contact with air during the earlier and freer access of air during the later stages of the roasting, to produce a mixt. of oxide, sulfate and sulfide. The roasted mixt. is treated with HNO_3 and the nitrous fumes from this operation are mixed with the sulfurous gases from the roasting and the mixed H_2SO_4 and nitrosulfuric acid used for the conversion of the roasted mixt. into PbSO_4 , the HNO_3 thus produced being used in continuing the process with fresh portions of ore.

Paint- and varnish-remover. C. ELLIS. U. S., 1,167,641, Jan. 11. NaOAc or other acetate is dissolved in a mixt. of alc. and C_6H_6 or other organic solvents and heated with HCl or H_2SO_4 to effect esterification. Wax is added as a thickener. Cf. C. A. 9, 2601.

Paint- and varnish-remover. C. ELLIS. U. S., 1,167,640, Jan. 11. *o*-Anisidine

10 parts is mixed with naphthenic acid 15, benzal chloride 25, aniline 5, monochlorocresol 10, benzyl alc. 40, EtOH 10, Montan wax 4, paraffin 3 and soap 3 parts.

Paint- and varnish-remover. J. M. WILSON and C. V. BACON. U. S., 1,167,462, Jan. 11. Palm wax or candelilla wax is rendered effective as a thickener in paint-removers, in much less than the usual amts. necessary, by the colloiding action of H_3PO_4 or H_2SO_4 . A paint remover of this type may be made from C_4H_8 46, "methyl acetone" 46, concd. H_3PO_4 6 and palm wax or candelilla wax 2 parts. The use of H_3PO_4 gives the mixt. a very energetic action on linseed oil lead paints. In making the mixt. the wax is added last after heating the other ingredients together.

Paint- and varnish-remover. C. V. BACON and J. M. WILSON. U. S., 1,167,469, Jan. 11. A paint remover is made similar to that of the preceding pat. except that concd. formic acid or glacial HOAc is used as wax-colloiding agent. A mixt. containing HOAc is very effective in removing films of linseed oil-lead paint.

Wood filler, stain and polish. G. A. DENNIS. U. S., 1,168,485, Jan. 18. A mixt. of talc 90 and Mn borate, sulfate, oxide or oxalate 10 parts is mixed with linseed oil and the mixt. is applied to wood as a smoothing, filling and staining material.

Phenol-formaldehyde artificial resin. B. B. GOLDSMITH. U. S., 1,168,626, Jan. 18. PhOH and anhydroformaldehydeaniline are heated together in the relative mol. proportions of 3:1, the aniline liberated is sep'd. from the reaction products and the heating is continued until a resinous product is obtained which is sol. in acetone and may be molded or used in solvents to form a varnish.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Molecular weight determination of some vegetable oils. H. J. BACKER. Amsterdam. *Chem. Weekblad* 12, 1034-40(1915).—In addition to the ordinary consts. used for the identification of oils, the mol. wt., detd. by f. p. lowering in C_6H_6 , is proposed. Mol. wt. detns. were made on a number of oils, using 0.5, 1.0 and 2.0 g. oil to 15 cc. C_6H_6 , and it was found that Raoult's law does not hold at these concns. The values obtained run parallel to the sapon. no., which also is proportional to the mol. wt. of the saponifiable material. The f. p. detns. takes more time than the sapon. detns., and results are not so accurate, but the method should be of value in certain work.

GEORGE W. MOREY.

The hydrogenation of oils. L. HAMBURGER. *Chem. Weekblad* 13, 2-13(1916).—For the reduction of oils with H under a pressure of 9 atms. an apparatus was constructed resembling the one described by Stuckert and Enderli (cf. *C. A.* 7, 3254). The influence of temp., pressure, divisibility of the catalyst, and kind of oil (impurities therein) on the hydrogenation process was investigated. The hydrogenation of all pure oils with finely divided Ni, as a catalyst proceeds without difficulty; the same holds true for fatty acids obtained from very impure oils by distn. with steam *in vacuo*. The Ni catalyst was obtained by the reduction at 260-300° of Ni oxide, which had been previously pptd. on pumice stone. It appears that W, Mo, Th, U, Zr, Ti, V and Mn cannot be used as catalysts in the hydrogenation of oils. H. states that the claims by Ellis (U. S. pat. 1,026,156 (cf. *C. A.* 6, 2014)) could not be confirmed, not even when a H pressure of 200 atms. was applied.

J. T. FLOHL.

The use and valuation of solid lubricating fats in chemical factories. H. WINKELMANN. *Chem. App.* 2, 295-8(1915).—General remarks on the compn. and appearance of these lubricants, with simple methods for rough detn. of H_2O , weighting, consistence, melting and ignition points and resinifying p.

J. H. MOORE.

Optical dispersion of Chinese wood oil as an index of purity. E. E. WARR. *J. Ind. Eng. Chem.* 8, 126-8(1916).—A new method based on the observations of Brier (*C. A.* 9, 2459) is proposed, the necessary app. being the ordinary spectrometer with an autocollimating eyepiece. A cut of app. is given. A brass electrode arc lamp was used as the source of light. Compared to other fatty oils Chinese wood oil has an abnormally wide dispersion. The angle through which the table of the spectrometer must be rotated to focus properly the slit image upon the slit itself is the angle from which, knowing the angle of the prism, the n for any particular wave length may be calcd. By using a source emitting light of different wave lengths the relative dispersion for any two can be calcd. From this value, expressed in angular degrees or in vernier units, adulteration in Chinese wood oil can be estd. with remarkable accuracy. In W.'s results the greatest error was 0.5%, the oil containing 5% of adulterant. Expressed in vernier units, pure Chinese wood oil gave values of 267-269, while other oils, such as soy-bean, linseed and rape, gave values of 127-143. Tables, curves and formulas containing the necessary data are given. E. W. BOUGHTON.

The differentiation between fats of vegetable and of animal origin. F. H. VAN LÉENT. *Watergraafsmeer. Chem. Weekblad* 12, 86-92(1915).—A general article. containing little new material. The chief criterion for the differentiation, and for the estn. of the approx. amt. of vegetable and of animal fat in mixts., lies in the detn. of the m. p. of the sepd. phytosteryl and cholesteryl acetate crystals. The method recommended for obtaining these crystals is the extn. of the fat with EtOH, sapon. of the dissolved fat, extn. with Et₂O, and subsequent conversion to the acetate. Before detn. of the m. p. the product should be 4 times recrystd. The m. p. of cholesteryl acetate is, in general, from 113.6° (from beef fat) to 114.1° (from lard), though fish fat yields an acetate m. at 116.4°; phytosteryl acetate is of more variable m. p., although in general it melts about 129° (cocoa butter) to 132° (soy bean oil). Other factors are discussed. GEORGE W. MOREY.

Acid and ester values. (New method for the determination of acid and ester values of fats, fixed and essential oils, and waxes.) H. F. SLACK. *Chemist Druggist* 87, 673-4(1915).—About 5 g. sample is weighed into a 120 cc. CO₂ flask, warmed to 80°, neutralized to phenolphthalein with 0.1 *N* alc. KOH, 20 cc. of approx. *N* KOH dissolved in benzyl alc. is added and the whole is boiled under a reflux air condenser over a free flame for 5 min. It is then cooled to 100°, and the excess alkali titrated with *N* HCl after the addition of sufficient neutral alc. The advantages of the use of benzyl alc. are (1) it has better solvent action on fats and oils than EtOH, which facilitates the action of the alkali and (2) its high b. p. (200°) hastens the saponification, which is complete in 5 min. instead of the 1 hr. required by the old method. For smaller samples 0.5 *N* KOH in benzyl alc. can be used. The titration of the excess of alkali should be rapid since the color of the phenolphthalein quickly returns upon standing. Blanks should be run since benzyl alc. has small acid (0.41) and ester (8.85) values. S. also proposes to modify the Koettstorfer method by (1) limiting the amt. of neutral alc. in the acid value detn., (2) titrating the free acids with alc. KOH instead of aq. KOH, (3) using *N* alc. KOH for the saponification, and (4) const. agitation to break up the fat globules during saponification. By these means the time required for the saponification is reduced from 1 hr. to 30 min. C. O. EWING.

Unification of methods of fat analysis. C. N. NIEGHMANN. *Farben-Ztg.* 21, 207-9(1915).—Commenting on the report of leather chemists on the unification of methods of fat analysis (cf. *C. A.* 9, 1850), N. concludes that for the detn. of acid no. (1) 5 g. of sample should be taken or 10 g. of materials having low acid nos.; (2) 0.2 *N* aq. KOH soln. should be used for the titration; (3) if phenolphthalein is used as indicator, at least 2 cc. of a 1% soln. should be used. E. W. BOUGHTON.

Fat analysis. F. H. SMITH. *Chem. News* 112, 319-20(1915).—S. sought to combine in one operation detns. for sapon. no., sol. and insol. fatty acids and mean mol. wt. as follows: 5 g. of fat are weighed into a 250 cc. Erlenmeyer. To this 50 cc. of 0.5 N alc. KOH are added and the soln. heated under a reflux condenser on a water bath until saponified. The excess alkali is titrated with 0.5 N HCl and the sapon. no. calcd. The alc. is next evapd. and the residue dissolved in 100 cc. H₂O and enough HCl added to make 1 cc. excess over that required by the blank for the sapon. no. When the fatty acids are sepd. and cooled the acid soln. is decanted into a measuring flask of 1 l. The acids are allowed to solidify and are washed with H₂O. This is done 5 times, and the insol. acids are kept in the original flask where they are freed from alc. and dried to const. wt.; then they may be titrated. Two 100 cc. portions taken from the flask contg. the washings are titrated with 0.1 N KOH. The readings are multiplied by 10 and 5 is deducted for the excess of acid added to separate the fatty acids. The result is expressed as mg. KOH for 1 g. of sol. fatty acids. E. SCHERUBEL.

Three new vegetable waxes from Madagascar. A. HERBERT AND F. HEIM. *Bull. Office Colonial* 8, 86, 96-101; through *J. Soc. Chem. Ind.* 34, 1061(1915).—The plants from which waxes are obtained are *Cynanchum messeri*, *Euphorbia xylphyloides* and *E. stenoclada*. The best method of extn. consists in pounding the dried cut pieces on a cloth and then throwing them into boiling H₂O and removing the scum. A quicker method is to put the branches into boiling H₂O and then skim off the wax. The largest yield is from the 1st plant, 7 oz. being obtained from 6 small plants. The m. p. of each is 88° which is higher than that of any other wax. These waxes contained but little free acid; among the alcs. were cerylic and melissic. Etriacontane, C₄₁H₈₄, was also present. The const. for the waxes in the order given were: acid value 17.7, 28, 19.3; sapon. no. 159.6, 142.8 and 140; I no. 3.2, 5.3 and 5.9. The % of hydrocarbons were, resp., 11, 14 and 15. E. SCHERUBEL.

The history and knowledge of beeswax. HANNS FISCHER. Bremen. *Z. offent. Chem.* 21, 177-80(1915).—A continuation of a former article on the history of beeswax (*C. A.* 9, 867). The fact that after melting together European and Indian beeswax over water the calcd. const. are not obtained, is due to the changes in compn. brought about by the melting. The observed increase in I no. on heating shows that those constituents of the wax which absorb I are found among the non-volatile neutral ingredients. The acids and saponifiable matter of Indian wax are more easily changed by heating than those of European wax. The low acid no. of Ghedda wax seems to F. to be due to climatic conditions (temp. of 35° to 50°) and not to any physiological peculiarity of the Indian bees. *Melipona* and *Trigona* waxes often give normal acid numbers, so it seems that the rubber juice, which these insects mix with their wax, protects the wax from any great decompn. H. E. WOODWARD.

The practical value of the commercial analysis of beeswax. HANNS FISCHER. *Z. offent. Chem.* 21, 145-9(1915); cf. *C. A.* 9, 2157.—F. arrives at the conclusion that it is misleading to consider a strongly positive stearic acid reaction occasioned by palmitic acid as doubtful when the wax appears to be free from objection otherwise. The constant known as normal number is further defined. The test for neutral matter is not accurate. The recent methods of commercial analysis do not have the value of an exact detn. of purity, and do not show whether the material is free from objection.

H. E. WOODWARD.

New method for the determination of fatty acids in soap. H. F. SLACK. *Pharm. J.* 95, 696-7(1915).—Dissolve 5 g. of shredded soap in about 10 cc. of glycerol with heat. Slowly add 4 cc. of dil. HCl (1 in 4). Withdraw the liberated fatty acids into a 5 cc. graduated pipet, by the aid of hot H₂O if necessary. Suspend the pipet, with upper end closed, in H₂O at 50-55° and read the vol. of the fatty acids. To find %.

the sp. gr. must be detd. at the same temp. It does not vary much with the ordinary soaps. In using glycerol, the soap dissolves without froth, and the fatty acid layer is perfectly clear.

S. WALDBOTT.

Beechnut oil for the preparation of soap. FREUND. *Pharm. Zentralhalle* 56, 463-4(1915).—After the removal of the cold-pressed edible oil of the nut of the beech, *Fagus sylvatica*, the less valuable hot pressed oil can be used for the manuf. of soap.

C. O. EWING.

Distillation of mineral oils, liquid hydrocarbons, fatty acids and similar products (SINGER) 22. Determination of the origin of hydrogenated fats (PRESCHER) 12.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Artificial tannins. R. LAUFFMANN. *Kunststoffe* 6, 1-4(1916).—A review and discussion of the patents for "synthetic" or "artificial tannins."

F. W. S.

Artificial tannin derived from gallic and arsenious acids. ANON. *Conceria* 22, 147(1914).—On boiling a soln. of gallic and arsenious acids Schiff obtained a product which, like tannin, pptd. gelatin. This compd. was termed digallic acid. Subsequent expts. failed, however, to give uniform results and the product decompd. with reformation of gallic acid which had no tanning action. It is probable that the product was a definite compd. of gallic and arsenious acids of slight stability.

H. S. PAINE.

Analysis of one-bath chrome liquors; basicity. ERNEST LITTLE. *J. Am. Leather Chem. Assoc.* 11, 61-6(1916).—The methods given are essentially the same as those of the Leather Industries Laboratory Book (H. R. Procter, *C. A.* 9, 1258; cf. Balderston, *C. A.* 9, 534). Directions are given for bringing the ratio of acid to basic radical in the chromium compound to a certain stated value assumed to be the best for successful tannage.

L. B.

Basicity of one-bath chrome solutions. FRANK N. HARRAP AND HARRY HAYES. *Collegium (London)* 1915, 305-12; *J. Am. Leather Chem. Assoc.* 11, 66-74(1916).—Cr is estd. as usual (see preceding abstract). Six methods for detn. of acid are discussed, Procter-McCandlish, Körner, Alden, Stiasny (*C. A.* 1, 1915), Bateson, and Kopecky. No definite preference is stated. It is known that in using methods involving the addition of an excess of alkali, results depend on the amt. of excess, which must therefore be closely controlled. It is assumed that differences are due to adsorption of excess alkali by the pptd. Cr(OH).
L. B.

Water penetration apparatus for leather. C. T. GAYLEY. *J. Am. Leather Chem. Assoc.* 11, 36-40(1916).—The piece of leather to be tested is subjected to the pressure of a column of water 24 in. high and 2 in. in diameter. A copper disk touches the lower side of the leather, and when the water has penetrated to the copper, an electric circuit is completed, ringing a bell and stopping a clock. Illustrations, with dimensions and directions for construction are given.
L. B.

Contribution to the knowledge of chestnut extract. L. POLLAK. *Collegium* 1915, 435-40.—For the estn. of "lignin" in wood P. uses the method of Cross, Bevans and Briggs (*C. A.* 1, 2942) and extends it to exts. by drying them 2 hr. at 100° after 3 times evapg. to dryness with sand on a water bath to drive off aldehydes, which would absorb phloroglucinol and so alter the phloroglucinol absorption value on which the method depends. P. finds this value for chestnut ext. to be about half that of the wood, while the extd. wood has as high a figure as the new. He concludes that during extn., especially at high temps. and pressures, a gradual breaking down of the wood-

substance takes place, more phloroglucinol-absorbing substance being formed, and that higher non-tannin content of such exts. is not due to breaking down of tannin, but that portions of the wood otherwise insol. are broken down by prolonged heat and pressure. Figures are given for many samples of wood and ext. L. B.

Degreasing of hides by a wet process. ANON. *Conceria* 22, 337(1914).—The series of non-inflammable products obtained by the substitution of Cl in the paraffin and olefin hydrocarbons may find an extensive application in the removal of fat from various hides. Tetrachloroethane is the most frequently used of these compds., but pentachloroethane and di-, tri-, and tetrachloroethylene may also be employed. The solvent is mixed with H_2O at $35-40^\circ$ and the green hides are worked in the mixt. until the fat forms a colloidal soln. which separates on cooling; the solvent may then be recovered by drawing off and filtering. In one instance 10 dozen ram skins were treated with 20 kilos of tetrachloroethane and 80 l. of water at 40° . After 2 hrs. the fat was practically eliminated and the hides were removed; liquid fat collected at the surface of separation of the H_2O and tetrachloroethane on cooling. The solvent was then drawn off and the last traces of suspended fat were removed by passing through a filter press. The hides were then washed with H_2O and another portion of solvent; the fat which was removed was recovered in the usual manner. The above process should be conducted in the dark to as great an extent as possible, inasmuch as light has a decomposing action on the Cl substitution products used in this method of degreasing. H. S. PAINE.

Theory of dehairing. ANON. *Conceria* 23, 496(1915).—Dehairing may be accomplished through the chem. influence of alk. upon the substance of the hide or through the influence of NH_3 which is developed by putrefaction. There is a difference in the H_2O content of hides which have been subjected to these processes. Hides which have been subjected to warm putrefaction have the smaller H_2O content. The reason for this phenomenon may be found in the van't Hoff-Arrhenius theory. In view of the relatively slight electrolytic dissociation of NH_4OH the difference between the osmotic pressure at the interior and exterior of the hide is small and there is consequently little flow of liquid. In the case of dehairing by liming the $Ca(OH)_2$ is a relatively strong base; the substance of the hide is readily permeable by $Ca(OH)_2$ in view of the degree of dissociation of the latter. The hide becomes greatly swollen as a result of the penetration of $Ca(OH)_2$. If the lime liquor becomes putrid with time (and hence enriched in its content of NH_4 salts and combinations of organic bases) the electrolytic dissociation of the $Ca(OH)_2$ diminishes and the osmotic pressure is consequently decreased; the swelling action of a lime liquor is, therefore, diminished by putrefaction. When Na_2S is used in connection with $Ca(OH)_2$ the formation of $NaOH$ must be taken into account in connection with the principles stated above. H. S. PAINE.

The black dyeing of furs ("Cosmos") 25.

Tanning. J. G. STODOLA. U. S., 1,167,951, Jan. 11. Hides are pickled in a dil. soln. of $NaCl$ and H_2SO_4 , treated with a Cr tanning soln. and then treated with a soln. of basic Fe and Cr salts such as basic sulfates, allowed to drain after removal from the soln., and washed with lukewarm H_2O , after treatment with an alk. soln. to fix the Fe in the leather.

Adhesive. E. WIGAR. U. S., 1,168,137, Jan. 11. Gelatin, 600 g., is digested in a soln. of 3% H_2O_2 , 1000 g., containing 10% $HOAc$ and 8% $ZnCl_2$ and the product is filtered after standing for several days. A clear colorless product is obtained suitable for prep. microscopic specimens or uniting glass.

Only a few days left in which to help insure favorable action as to publication of the Ten-Year Index by sending in your subscription before the time of the Spring Meeting, April 18-21.

Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

APRIL 10, 1916.

No. 7

I. APPARATUS.

L. C. JONES.

Simple apparatus for the accurate and easy determination of surface tension, with a metal thermoregulator for the quick adjustment of temperature. WILLIAM D. HARKINS AND F. E. BROWN. *J. Am. Chem. Soc.* 38, 246-52(1916).—The glass or metal tip from which the drop is suspended in this modification of the drop wt. method is ground as nearly as possible in a perfect circle, and the edges of the tip are sharp. Above the tip the glass capillary is ground to fit into a Monel-metal stopper, which in turn fits the weighing bottle into which the drops are caused to fall. This glass capillary tube is bent into an inverted U, and the other limb of the tube passes down into a second weighing bottle which contains the liquid whose surface tension is to be detd. The whole app. is contained in a metal box with a water-tight cover and fitted with a simple leveling app. The rate of formation of the drop is controlled by an aspirator consisting of a buret-shaped tube with a capillary tip filled with Hg. The thermoregulator is of Ni-plated steel filled with Hg, thermal lag being thus largely eliminated. It is fitted with a threaded metal head which allows the rapid (coarse) adjustment of the temp. at which the regulator is to operate. The finer adjustment is then made with a wire attached to a threaded head and fitting into a narrow glass throat in the movable head. This glass head is ground into the metal parts and makes it possible to see the wire during adjustment. E. B. MILLARD.

A new form of gas buret. HAMMERMAN. Ölsnitz. *Chem. Ztg.* 40, 84(1916).—The app. is for lecture purposes. It consists of a 3-neck Wouff bottle with tubulure at the bottom. One neck carries a thermometer, the middle neck a 3-way cock connected with a rubber bulb, the other neck a Y U-tube, the outer vertical arms of which carry a measuring buret and a leveling tube, and the stem reaching below the surface of H₂O in the bottle. Directions for operating are given. J. H. MOORE.

A new "hot air" Teclu burner. PAUL VERBEEK. *Chem. Ztg.* 39, 948(1915).—The app. has 2 concentric tubes, the inner, gas tube, being slightly longer than the outer. The air drawn in by the gas passes downward between the tubes and is thus preheated by radiation from the flame and by the hot upper ends of the tubes. Five cuts show the construction. J. H. MOORE.

Simple sodium lamp for polariscope. G. K. FORESMORE. *J. Ind. Eng. Chem.* 8, 165(1916).—The app. consists of a piece of asbestos board 4 x 4 x 1/8 in. with a slit 3 x 1/4 in., 1 in. from the edge. This is supported about 1/4 in. above a wing-top flame which is directly under the slit and parallel to it. The edges of the slit are moistened with a satd. soln. of NaCl. A broad double flame is formed, easily located with the instrument. H. L. OLIN.

New Röntgen tube for spectroscopic purposes. M. SIEGBAHN. *Verh. deut. physik. Ges.* 17, 469-70(1915).—A tube of porcelain with a metal chamber having a conical end with arms turned into it to increase the cooling by radiation. The anticathode is cemented directly to this metal end. E. B. MILLARD.

An apparatus for mixing powdered substances. J. HUDIG. *Chem. Weekblad* 12, 984-8(1916).—The substances to be mixed enter a vertical tube through a funnel and

fall into a tray which divides the falling mass into 4 portions. The trays are removed and replaced by empty ones and the filled trays are now successively emptied into the funnel so that the division is repeated. Experiments with white and black oats, kainite and $(\text{NH}_4)_2\text{SO}_4$, powdered Na_2SO_4 and crystd. CuSO_4 showed that the mixing is sufficiently complete after 4 manipulations. The app. is especially recommended for sampling and in the case where thorough mixing of soil with fertilizer is needed for experimental work.

J. T. FLOHL.

Aluminium as construction material in the chemical industry. OTTO BECHSTEIN. *Chem. App.* 3, 17-9(1916).—Since the introduction of autogenous and elec. welding it is possible to construct Al app. of large dimensions and of any form for a large variety of purposes, a partial list of which is given. Its resisting power to acids, especially weak org. acids, makes it greatly superior to Fe, Cu or brass, not only because its salts are non-toxic but also because the goods are not discolored.

J. H. MOORE.

The Cochius automatic weighing machine for liquids. W. J. PENARD. *Arch. Suikerind.* 23, 699-702(1915).—Two rectangular tanks, ABCD and GHKL, of equal

size and wt., are mounted side by side at an angle to each other. The system revolves about S. A spout is moved by a system of levers operated by the tanks themselves, to fill the tanks alternately; and they are emptied by a valve in the bottom which is opened by striking a stop as the tanks trip. Suitable buffers are placed so that the tank which is filling is held perfectly horizontal, but the springs are so arranged that at the moment of balance there is no support from the springs.

Advantages claimed are simplicity, reliability, uninterrupted flow of juice, and no inaccuracy from solids depositing in the tanks.

W. L. BADGER.

The Cochius automatic weighing machine. C. J. TÖNJES. *Arch. Suikerind.* 23, 1056-8(1915); cf. preceding abstract.—A discussion to show that if one compartment contains any ppt., the weighing will be false. W. J. PENARD. *Ibid* 1116-7.—The presence of ppt. does not cause any error. J. SPAICH. *Ibid* 1217-19.—Another line of reasoning to show that the presence of ppt. does not affect the accuracy.

W. L. BADGER.

Mills for grinding straw, dried potatoes, refuse, etc. J. E. BRAUER-TUCHORZ. Hanover. *Chem. App.* 3, 15-7(1916).—Descriptions, with 3 cuts. J. H. MOORE.

New methods for washing and distilling liquids. C. H. BORRMANN. *Z. angew. Chem.* 28, I, 377-80, 381-8(1915).—B. reviews some recent installations for the washing and continuous distn. of liquids. Descriptions and illustrations are given of installations used for washing paraffin oil produced from brown coal tar, continuous production of nitrobenzene, and continuous distn. of alc., Br, petroleum, coal and pine tars and fatty acids.

H. R. GUNDLACH.

Apparatus for the determination of the surface tension at the interface between two liquids (HARKINS) 2. Carbon helix resistance furnace and a temperature recording apparatus (JANECKE) 4.

Column apparatus for distilling alcohol.

Hydrogen sulfide generator. R. M. F. tube II (having sr

S., 1,169,122, Jan. 25.

70,953, Feb. 8. The

the bottle 5 with acid

as indicated. H_2S generated is passed into a pptn. flask 7 containing a soln. to be reacted upon and when the air has been displaced the valve 21 is closed; back pressure in the generator then forces the acid below the level of the solid sulfide in the tube 11 and stops the generation of H_2S . The bulb 26 may be used to force air into the generator and start the operation at a higher pressure. The tube 22 serves as a pressure indicator.

Retort for effecting synthetic reactions under high pressure. J. R. WATSON. U. S., 1,169,893, Feb. 1. The retort described is used for the synthetic production of phenol, α -naphthol, toluene, pyrocatechol, etc., or for

reactions with alkalis and HCl , in which high pressures are used. The retort is formed with a seamless flask 1 of drawn metal rotatably mounted on journals at the points 5 and 6 and carrying elec. resistance heaters 9 insulated from the retort

itself. The temp. is controlled by a thermostat 14 and a safety plug 24 limits the max. pressure.

Heating furnace. H. HILLEBRANDT, JR. Ger., 285,372, May 14, 1912. Addition to 257,716. The furnace is provided with a cooling device, and is used for heating and cooling the charge in a gas atm. with exclusion of air. Cf. C. A. 9, 398.

Filters. F. P. CANDY. Brit., 21,120, Oct. 17, 1914. Downwardly acting mechanical filters wherein the filter bed is divided into a number of sep. compartments and a filtering plant comprising a number of sep. filters. Non-return valves are provided on the pipes serving for the exit of the filtrate, one or a few of such valves being opened or by-passed during the washing operation so as to limit the supply of wash-water to one or a small proportion only of the compartments or filters, resp. The valves may be opened by hand or mechanically so that the wash-water is supplied to each filtering element in succession.

Magnetic separators. S. BRÜCK. Brit., 20,551, Oct. 5, 1914. Addition to 11,898, 1911. (C. A. 6, 3087.) In a magnetic separator in which fine-grained material passes through the magnetic field under the action of some driving force other than gravity alone, as described in the parent specification, the magnet surrounding the container is formed with inwardly projecting poles parallel to the vertical axis of the vessel. Also, the movement of the material along the magnetic field is assisted by periodically interrupting the energizing current and simultaneously weakening the residual magnetism.

Magnetic separators. S. BRÜCK. Brit., 20,552, Oct. 5, 1914. The containing vessel, instead of being provided with a single magnetic field as described in the parent specification, has several magnetic fields arranged helically so as to utilize the entire external surface of the containing vessel. Cf. preceding patent.

Electromagnetic separator with zones of different magnetic strength. A. F. JOBKE. Ger., 285,826, Nov. 26, 1913. Addition to 278,248 (C. A. 9, 982). The separator specified in the principal patent is modified in that a difference in magnetism is effected by a cross-sectional alteration of the several poles.

Washing, dyeing, bleaching, tanning. J. HAYWOOD. Brit., 21,161, Oct. 19, 1914. An app. for washing clothes, textiles, crockery, and other articles, for dyeing, scouring, or bleaching, for tanning, or for otherwise treating articles with hot or cold liquids, comprizes an outer, liquid-tight vessel, an inner vessel which contains the articles and is perforated at the ends and bottom, a propeller situated between one end of the inner vessel and the outer vessel, baffle-plates attached to the outer vessel to deflect liquid over the edge of the inner vessel, and one or more perforated steampipes below the bottom of the inner vessel.

Burners. H. N. DAVIS and W. R. TWIGG. Brit., 20,538, Oct. 5, 1914. A Bunsen or like burner having a number of outlet passages with independent walls is provided with 2 or more plates which subdivide the passages and bridge the intervening gaps so as to form heating-chambers for the air supplied to the flame.

Twenty-third annual report of committee on atomic weights. Determinations published during 1915. G. P. BAXTER. *J. Am. Chem. Soc.* 38, 489-96(1916).—Bibliography and discussion of new detns. The new values for those elements whose at. wts. have been changed 0.1 unit or more are Sn 118.7, Pb 207.20, Ra 226.0, U 238.2, Yb 173.5 (old value 172.0), Pr 140.9, Yt 88.7, Lu 175.0 (old value 174.0). E. B. M.

Atomic weight of cadmium. W. OECHSNER DE CONINCK AND GERARD. *Compt. rend.* 161, 676-7(1915).—The metal was dissolved in H_2SO_4 and pptd. (together with Cu and a little Zn) with H_2S ; this ppt. was dissolved in concd. HCl, evapd. to expel excess acid, then treated with a large excess of a concd. soln. of $(NH_4)_2CO_3$, by which Cd alone was pptd. The $CdCO_3$ was washed, dried and weighed. From the loss of wt. when this carbonate was ignited first to CdO, then reduced in a stream of H to the metal, the at. wt. was calcd. As a mean of 5 detns. on about 0.6 g. samples of carbonate, the value 112.32 is given for the at. wt. of Cd, with the extreme values of 112.28 and 112.37. No details of manipulation, corrections applied, etc., are given.

E. B. MILLARD.

Inclusions in the silver voltameter deposits. G. W. VINAL AND WM. M. BOVARD. *J. Am. Chem. Soc.* 38, 496-515(1916); cf. C. A. 8, 1391, 3154.—The same instruments were used as in the previous work at the Bur. Standards and at Princeton (C. A. 9, 412, 1582), and the $AgNO_3$ was prepd. by either of the methods previously described. Deposits were heated to slightly above 600° , both with a flame and in an elec. furnace. Losses in wt. were found which indicated inclusions averaging 0.0040% for pure electrolytes, and higher for impure electrolytes. Heating to 625° for 30 min. caused more alloying than heating to 675° for a short time. After the Ag was removed a brown or black stain was left which could not be removed by scrubbing without considerable abrasion of the Pt surface, and which disappeared completely on being heated to bright

redness without lessening the capacity of the stain to make trouble. The most accurate value for the abs. electrochem. equiv. of Ag is that recommended as the international standard, 1.11800 mg., making the value of the faraday 96494. A rounded value 96500 is recommended. Inclusions on polished Pt surfaces and matte surfaces were the same within exptl. errors. Inclusions between the cup and the deposit were a negligible part of the whole. Strong heating of the cups does not lessen the "vol. effect" when this is present. No evidence was found of the existence of a heavy anode ion.

E. B. MILLARD.

Atomic structure. V. Periodic system and the properties of the elements. WILLIAM D. HARKINS AND R. E. HALL. *J. Am. Chem. Soc.* 38, 169-221 (1916); cf. *C. A.* 9, 2335.—A periodic table is presented which shows graphically the relations between the main and sub-groups of the elements; periodic tables which have been designed formerly do not show this. The elements are arranged in the order of their atomic numbers, and no blanks are left for unknown elements which do not correspond to the at. numbers detd. by Mosley. This table also plots the elements according to their at. wts., so that isotopic forms of an element may be shown graphically on the table, and the α and β decompns. of radioactive elements may also be depicted. Both the zero and 8th groups fall naturally into the system, which is best represented as a helix in space, but may also be shown as a spiral in a plane. The elements are divided into cycles, contg., resp., 4^2 , 6^2 , and 8^2 elements, with the latter part of the 3rd cycle missing, and the cycles are divided into periods, with 2×2^2 in the first two periods, 2×3^2 in the 2nd two periods and 2×4^2 in the 3rd two periods. These relations are undoubtedly a numerical expression of a function connected in some way with the system, according to which the atoms of the elements have been built up. Whenever the valence drops in passing along the continuous line connecting the elements in the order of their at. numbers, it always drops 7, either from 7 to 0 or from 8 to 1, and in the latter case there is evidenced a certain sluggishness in the drop (*e. g.*, in the valences of Cu, Ag and Au higher than unity). Whenever the group numbers in any one division differ considerably, the elements in the sub-groups are quite different chemically from the members of the main group, although they are in general alike in valence. As the group numbers in the division approach each other in magnitude the elements of the sub-group become much more like those of the main group. On the outer cylinder the main groups become less positive as the group number increases, while the corresponding sub-groups become more positive. The rare earths are put in the 3rd group, since if they are distributed around the table there are not enough known and undiscovered elements together to go around, and since the valence of the rare earths is 3 and the chem. characteristics are very similar to those of yttrium which is always classified with the rare earths. The rare earths therefore form a group similar to the 8th group elements and fill the same sort of a place in the system, that is, these are the only elements for which the at. number rises in steps of one while the valence remains const. Main group elements in the table lie on a primary loop of the helix; sub-group elements, including the 8th group, lie on secondary or inner loops; while the rare earths lie on a tertiary loop which connects Ce with Ta. A number of figures are used to show the relationship between the at. numbers and the following properties of the elements: at. vol., m. p., compressibility, coeff. of expansion, cohesion, atomic frequency, and magnetic susceptibility. An important relationship found is that the distances to which the centers of the monoatomic atoms of the He or zero group elements approach during collision is proportional to the 5th root of the at. number, and presumably to the 5th root of the number of electrons in the atoms external to the nucleus. Data are given which seem to support the idea that the large variations in what may be called the cohesional properties of the elements in a single period of the periodic table seem to be

of the asymptotic formula, (5) application of the Lorentz-Wien theory of impacts, and (6) a comparison with exptl. results.

E. B. MILLARD.

Influence of gases on the emission of electrons and ions from hot metals. O. W. RICHARDSON. *Proc. Roy. Soc. London (A)* 91, 524-35(1915); cf. *C. A.* 9, 2620. —The variations of the consts. A and b in the equation for the satn. current density i of the electron current from hot bodies, $i = AT^{1/2}e^{-b/T}$ where T is the abs. temp., are discussed, making use of the data of Langmuir (*C. A.* 9, 985, 1264, 1562). A theoretical discussion of the effect of gases, especially impurities in the gases, is given from a different standpoint from that of Wilson (1908). There is evidence that the linear relation between the consts. A and b in the emission temp. formula holds for positive ions as well as for electrons. If the change in the emission const. for Pt which is caused by H is an effect of positive H ions present in the surface layer, it is equally likely that the contrary effect with W in various gases is due to negative ions, originating from the gas, which are in a similar condition to the positive ions in the case of Pt. At least it seems improbable that the effects are not attributable to a similar cause acting in opposite senses in the case of the 2 metals.

E. B. MILLARD.

Law of fall of a drop of oil in air and the charge of the electron. A. SCHIDLÖF AND J. MURZYNOWSKA. *Arch. sci. phys. nat.* 40, 486-504(1915); cf. *C. A.* 10, 550. —The exptl. method was given in the first paper. In the present paper many of the exptl. details and methods of calcn. are discussed. The value of e is 4.738×10^{-10} e. s. u., and the value of Avogadro's N is 6.11×10^{23} . No charges were found which were not whole multiples of the electronic charge.

E. B. MILLARD.

The value of the electronic charge calculated from the Brownian movements. A. TARGONSKI. *Inst. of Physics, Geneva. Compt. rend.* 161, 778-81(1916). —There are two methods of deducing the magnitude of the elementary elec. charge: (1) by observing the motion of very small particles in an elec. field (Millikan); (2) by observing the Brownian movements. The elec. field method gives very consistent results with particles formed at low temp. but very low results with particles produced in a metallic arc. T. therefore concludes that the arc gives particles of irregular shape or abnormal density. The results obtained with the Brownian movements are independent of the shape and density of the particles. With this method all observers agree fairly well, but the results have been uniformly lower than those obtained by the elec. field method with oil drops, etc., though far higher than those obtained with particles from the arc. T. now finds, from results by himself and Fletcher, that the Brownian movement result approaches nearer to Millikan's ($e = 4.77 \times 10^{-10}$) as the ratio of the mean free path of the gas becomes larger relatively to the diameter of the particles. It would therefore seem that the theory of the Brownian movement does not apply rigorously unless the radius of the particles is small compared to the mean free path of the surrounding gas.

W. P. WHITE.

Theory of the calculation of the rise and fall experiments on particles with Brownian movement. D. KONSTANTINOWSKY. *Physik. Z.* 16, 369-72(1915); cf. *C. A.* 9, 2182. —Theoretical. Further discussion of the question of charges smaller than the electron. (Cf. Schrödinger, *C. A.* 10, 299; Ehrenhaft, *C. A.* 9, 411, 1000 and following abstr.) A simpler method of calcn. for the rise and fall expts. is given. There is no doubt that such charges exist, nor that they are in cases as small as $1/100$ of the electronic charge.

E. B. MILLARD.

Properties of small droplets of pure mercury. A. SCHIDLÖF. *Physik. Z.* 16, 372-5(1915). —Reply to Ehrenhaft (*C. A.* 10, 408) on the same subject. The application of formulas by E. is wholly unjustified.

E. B. MILLARD.

Electron theory of metals and Nernst's formula. K. F. HERZFELD. *Pola. Physik. Z.* 16, 324-62(1915).—It is postulated that atoms, ions and free electrons are all present in the metal and that each is in equil. with the atoms, etc., of any other medium (e. g., water) making contact with the metal. Nernst's formula for the relation of potential difference to concn. can therefore be brought into the calcns. The chief conclusions of the mathematical treatment are that the number of free electrons in the metal is small and that the entropy constant differs from what the quantum hypothesis indicates.

W. P. WHITE.

Capillarity theory of crystal structure. P. EHRENFEST. *Ann. Physik* 48, 360-8 (1915).—A mathematical paper.

H. JERMAIN CREIGHTON.

The production of motion by the molecular directing force in liquid crystals. O. LEHMANN. Karlsruhe. *Ann. Physik* 48, 177-92(1915).—L. opposes the supposition that the mols. of liquid crystals are identical with those of isotropic fusions. When liquid crystals flow together, currents and motions are produced until the mol. directing force has the same value at all points, and thereby the surface energy becomes a minimum. This behavior is illustrated with crystals of ammonium oleate hydrate. A crystal drop of *p*-azoxyphenetole exhibits a rotatory motion on the addition of colophonium, when a temp. difference exists between the upper and under sides of the drop. This motion is referred to a change in surface tension resulting from the increase in temp. As the source of energy the surface energy comes into consideration, and as its source the chem. energy. It has not been possible to develop a rigid mathematical theory, on account of the complicated nature of the phenomena. H. J. CREIGHTON.

The structure of slimy crystalline liquids. O. LEHMANN. Karlsruhe. *Ann. Physik* 48, 725-69(1915).—Slimy cryst. liquids consist of chains of mols. so arranged with respect to one another that they behave like optical uniaxial straight threads. The influence of the mol. directing force is momentary. H. JERMAIN CREIGHTON.

The density of argon. H. SCHULTZE. Charlottenburg. *Ann. Physik* 48, 269-72(1915).—For the purest samples of A, the value 0.00178376 has been obtained for the d. at 760 mm. and 0°. The at. wt. of the element is, therefore, 39.945.

H. JERMAIN CREIGHTON.

Equation of state for gases and liquids. F. H. MACDOUGALL. *J. Am. Chem. Soc.* 38, 528-55(1916).—A mathematical discussion of the Dieterici equation of state $p = RTe^{-a/RT}/(v - b)$ and an indication of its accuracy. Methods are developed for calcg. *a* and *b* above, at, and below the crit. temp.; formulas are derived for calcg. the pressure of satd. vapor from the d. of liquid and vapor, and for calcg. the latent heat of vaporization from these quantities. Finally, the calcns. are applied to a study of iso-C₆H₁₂, H, and CO₂. The d. of a substance at abs. zero was calcd. as 4 times its crit. d.

E. B. MILLARD.

Properties of mixed liquids. I. Sulfuric acid-water mixtures. J. L. R. MORGAN AND C. E. DAVIS. *J. Am. Chem. Soc.* 38, 555-68(1916).—More than 100 detns. of the surface tension of 48 concns. of H₂SO₄ in H₂O at various temps. have been made by the drop wt. method, and formulas provided by which the surface tension and sp. cohesion can be calcd. at any concn. and for temps. between 0 and 50°. Both addition of H₂O to H₂SO₄ and of H₂SO₄ to H₂O increase the surface tension, so that different concns. of H₂SO₄ may have the same surface tension at the same temp. Addition of SO₂ to H₂SO₄ also increases the surface tension. The property-concn. curve indicates the existence of a hydrate H₂SO₄.H₂O at about 85% acid. From the Denison law that a

max. deviation from the mixt. law indicates a compd., hydrates with 1, 2, 3, and 12 mols. of H_2O per mol. of H_2SO_4 and 3, 4, or 5 mols. of H_2SO_4 per mol. of H_2O may be found from some property or other.

E. B. MILLARD.

Preliminary report on the diffusion of solids. C. E. VAN ORSTRAND AND F. P. DEWEY. U. S. Geol. Survey, *Prof. Paper* 95-G, 83-96(1915).—The coefficients of diffusion of Au into Pb at 100, 150 and 197° were found to agree closely with the values previously obtained by Roberts-Austen. Pressure appeared to increase the values for the coefficients. The theoretical values are deduced mathematically, and close agreement between observation and theory found. If minerals in the earth are capable of diffusing into each other under pressure, the argument for isostatic adjustment is greatly strengthened.

E. T. WHERRY.

Surface tension. I. Drop weight method for determining surface tension. W. D. HARKINS AND E. C. HUMPHREY. *J. Am. Chem. Soc.* 38, 228-36(1916).—Discussion of a modified method (cf. part II below); a liquid-liquid interface has been substituted for the usual liquid-air interface. The corrections calcd. by Lohnstein (*C. A.* 8, 1041) were not sufficiently accurate, so a new correction curve has been prepd. Values of the drop weight correction have also been calcd. (from Morgan's results). The curve showing these data does not fall on the correction curve of H. and H., though the discrepancies are not great. An attempt to find the cause of this discrepancy is in progress. If a function of r/a , where r is the radius of the tip and a is the square root of the capillary const., such as was calcd. by Lohnstein, be plotted against r/a from his calcs., the curve obtained coincides exactly with the exptl. values detd. from a number of different liquids, but the exptl. detd. values gave the smoother curve. Corrections for the drop weight are most accurately detd. for values of r/a in the neighborhood of 0.9. **II. Apparatus for the determination of the surface tension at the interface between two liquids.** *Ibid* 236-41.—The app. consists of a pipet of about 10 cc. capacity, the stem of which is graduated above and below the bulb. This pipet is one arm of a U-tube; the other arm is a capillary tube which is bent over at the top and which terminates in the dropping tip. A glass stopper is sealed above the end of the dropping tip, and closes the top of the beaker in which the lighter liquid is placed. When it is desired to save material in the lighter liquid a small vessel is used inside the beaker. Suction is used to force the drops over into the lighter liquid, which comes well above the dropping tip. Care is taken that the drop forms very slowly just before its fall, in order to have the drop free from currents and other motion. Details are also given of an app. for detg. the capillary rise with liquid-liquid interface. **III.** *Ibid* 242-6.—Detns. have been made by the capillary tube method of the interfacial tension between H_2O and C_6H_6 at several temps., between H_2O and Et_4CO_3 , xylene, $(CH_3)_3NC_4H_9$, toluene and hexane, resp., and between C_6H_6 and aq. solns. of NaCl, HCl, H_2SO_4 , HOAc, HCOOH and C_2H_5COOH , resp., at several concns. The organic acids lowered the interfacial tension between C_6H_6 and the solns.; HCl and H_2SO_4 produced almost no effect. NaCl increased it and bases lowered it slightly.

E. B. M.

The surface tension at the interface between two liquids. WILLIAM D. HARKINS AND E. C. HUMPHREY. *Proc. Nat. Acad. Sci.* 1, 585-90(1915); see preceding abstract.

E. B. M.

Surface tension of freshly formed surfaces of pure water and of salt solutions. G. MEYER AND H. STOCKER. *Z. Elektrochem.* 21, 5-11(1916).—A fresh, continually renewed surface may be formed by a stream flowing out of an elliptical opening which is vibrating around a cylindrical equil. position in such a way that the surface of the stream is symmetrical with respect to 2 planes passed through the axis of the stream and the long and short axes of the elliptical opening. The equation of von Bohr ex-

pressing the surface tension as a function of the d , velocity, wave length, vibration amplitude and mean radius of the stream, the viscosity of the liquid and the d of air was used. Expts. were made with 11 chlorides, 12 sulfates, and 10 other salts. The surface tension of fresh surfaces is roughly 0.5 dyne/cm. smaller than that of older surfaces, both for H_2O and the solns. Addition of salts to H_2O always increases the surface tension of the freshly formed surfaces.

E. B. MILLARD.

Determination of the composition of the vapors of calomel, the ammonium halides and phosphorus pentachloride from measurements of vapor pressure and density. ALEXANDER SMITH. *Z. Elektrochem.* 22, 33-7(1916).—Vapor pressures were measured using the 3 forms of app. described by Smith and Menzies (*J. Am. Chem. Soc.* 32, 897, 1413, 1541(1910); cf. *C. A.* 4, 2595; 5, 232, 612). The "static isoteniscope" was used to measure the pressure of Hg, of $HgCl$, and of mixts. of these 2 substances. There is no appreciable quantity of $HgCl$ in the vapor from calomel, practically all of it being Hg and $HgCl_2$. The vapor pressures of NH_4Cl , NH_4Br , NH_4I , NMe_4Cl , NMe_4I and PH_4I were detd. in previous expts. (cf. S. and Calvert, *C. A.* 8, 3139; S. and Lombard, *C. A.* 9, 748, 2614), and the d was then detd. for each vapor at several temps. This was done by weighing a small quantity of the solid salt into a small bulb, then sealing it on to a capillary which led to a much larger bulb, evacuating the 2 bulbs, heating in a bath of fused $NaNO_3$ and KNO_3 at the desired temp., and detg. the amt. of vapor driven into the larger bulb. The vapor d of NH_4Cl increased with the temp., since the pressure of satd. vapor increases rapidly. The degree of dissociation is nearly const., and lies between 66.8% at 280° and 62.8% at 330° . The mean (calcd.) value for the heat of vaporization was 32.9 kg. cal., and the heat of dissociation was $-12800 - 0.00967 T^2$ g. cal. per mol. The degree of dissociation of NH_4Br is a max., 39%, at 320° and falls off regularly to 8 or 10% at 388° . Above 320° the heat of dissociation of NH_4Br is therefore positive. The NH_4I reaction seems to be partly one of the dissociation of polymerized NH_4I to simple mols. below 340° , for the values of the d of the vapor are greater than correspond to no dissociation at all. At 300° at least 24% of NH_4I is associated (assuming the associated mol. to be $(NH_4I)_2$), and at least 17% is dissociated. A value of the heat of vaporization was calcd. as 18.0 kg. cal./mol. at 300° , and 24.2 kg. cal./mol. at 380° . The value 44.5 given by Johnson was calcd. on the erroneous assumption of 100% dissociation. Less exact detns. of the vapor d of PCl_5 showed an almost const. degree of dissociation of about 5%. The degree of dissociation is strongly influenced by slight changes in the d of the vapor. The heat of vaporization is for all temps. between 90 and 160° 15.5 ± 0.3 kg. cal./mol. Some errors in a paper of Holland (*C. A.* 6, 3215) are pointed out. See following abstract.

E. B. MILLARD.

Dissociation of gaseous acetic acid and phosphorus pentachloride. Correction. W. NERNST. *Z. Elektrochem.* 22, 37-8(1916); cf. *C. A.* 6, 3215 and preceding abstract.—N. has corrected the numerical errors in the paper of Holland (deceased). New values for the degree of dissociation and vapor d are given for temps. between 413 and 485° for $HOAc$ and between 462 and 623° for PCl_5 .

E. B. MILLARD.

The theory of peptization. W. D. BANCROFT. *J. Phys. Chem.* 20, 85-117(1916).—Accepting Freundlich's generalization, that all adsorption is accompanied by a lowering of the surface tension of the adsorbing phase, a theory of peptization follows, in that any substance which is adsorbed by a second will lower the surface tension of the second substance, and will therefore tend to disintegrate it, or to peptize it. If every adsorbed substance tends to peptize the adsorbing substance one may expect to get peptization by a solvent, by a dissolved nonelectrolyte, by an ion, by a salt, by a colloid. Adsorption decreases in general with rising temp., but so also does the cohesion of the adsorbing substance; there may, therefore, be peptization by a solvent at high

temp. when it does not occur at lower temp. Instances of this are glass and water, vulcanized rubber and organic solvents, gelatin and water. Instances of peptization by a dissolved nonelectrolyte are sugar or glycerol and hydroxides in water, ether and pyroxylin in alcohol; of ion peptization in water are AgBr and KBr, SiO_2 or $\text{Cr}(\text{OH})_3$ and KOH; Al_2O_3 and acids; Cr_2O_3 and CrCl_3 . No cases of peptization by a sol. undissociated salt have been studied. If impure Hg is shaken with water there is peptization by an oxide film. Instances of peptization by a colloid in water are AgBr and gelatin, alkaline Cr_2O_3 and hydrous ferric oxide, gold and stannic oxide. There is no necessary connection between amount of adsorption and ease of peptization. A coarse-grained, porous ppt. may be peptized more readily than the same mass in a more dense form. Von Weimarn's theory of peptization is inadequate. H. I. MATTILL.

Colloidal solid solutions. D. MCINTOSH AND R. EDSON. *J. Am. Chem. Soc.* 38, 613-5(1916).—Aq. salt solns. were placed in Cu tubes and plunged into CO_2 -ether mixts.; the frozen block was removed by dipping the Cu tube in H_2O for a moment. The frozen material resembled ice, but was more opaque and not so hard. It was perfectly homogeneous and showed no evidence of the formation of crystals of ice or salt. These solns. conduct electricity at low temps.; a 20% soln. of KI at -80° showed the color of I at the anode instantly when 110 v. was applied. Since the solns. melt sharply at the f. p. of the soln., their use is suggested as a means of maintaining const. temps. in Dewar tubes for short periods. Cond. expts. have been made on 10, 20 and 30% KI at temps. from -10 to -35° , and the cond. was found to increase most rapidly at -21° (the cryohydric temp. for KI soln.) so that it appeared some sepn. into salt had taken place. Further expts. were made with N , 0.5 N and 0.25 N HCl from -10 to -75° without finding here an abnormal increase at any one temp. E. B. M.

Effect of freezing on certain inorganic hydrogels. H. W. FOOTE AND BLAIR SAXTON. *J. Am. Chem. Soc.* 38, 588-609(1916).—The method used consists in freezing the ppt., of known total H_2O content, in a dilatometer and measuring the expansion caused by the freezing of the uncombined H_2O . From this expansion the amt. of H_2O frozen can be calcd., and the "combined" H_2O detd. by difference. A dilatometer of the usual form was calibrated with Hg and filled with ligroin when changes in vol. were observed. The temp. of the dilatometer was lowered gradually to about -20° , then rapidly to -30° . Preliminary detns. were made with sand and H_2O , lamp black and H_2O , and $\text{Ca}(\text{OH})_2$ and H_2O . Expts. were then made on $\text{Al}(\text{OH})_3$, silica and $\text{Fe}(\text{OH})_3$ gels of various concns. Freezing $\text{Al}(\text{OH})_3$ appears to increase the free H_2O at the expense of the capillary H_2O ; the capillary H_2O is decreased also by repeated freezing. The total free and capillary H_2O increased with long standing of the gel (8 months), but the data do not show whether this extra freezable H_2O comes from that which was actually combined with the Al_2O_3 or whether it was capillary H_2O of too low a f. p. to appear earlier. In SiO_2 gels the behavior of H_2O is quite different, showing little change on repeated freezings. The apparent capillary H_2O (*i. e.*, H_2O freezing below -6°) amounted to over 0.7 g. per g. of SiO_2 . Capillary H_2O in $\text{Fe}(\text{OH})_3$ is held more firmly, or is in smaller capillaries, than in either of the other gels. The work is being continued. E. B. MILLARD.

Double refraction of vanadium pentoxide sols. H. FREUNDLICH. *Z. Elektrochem.* 22, 27-33(1916).— NH_4VO_3 may be changed into V_2O_5 by addition of HCl or gentle ignition, and the resulting oxide may be peptized after washing out. The sol is red-brown, almost completely clear in transmitted light and, if not too concd., little more viscous than H_2O . It is a negative hydrophobic sol, easily coagulated by electrolytes, and if pptd. by weakly coagulating electrolytes (KCl), is easily peptized again. When stirred with a glass rod and viewed in reflected light the sol is filled with yellowish

glittering streaks as if there were fine crystals suspended in it. In transmitted light the sol remains clear but there are dark streaks in it. If it is brought between crossed nicols the field remains dark so long as the sol is not disturbed. If it is stirred the field becomes bright at once. Many of the V_2O_5 preps. were so sensitive that one had only to shake the vessel gently between the nicols to illuminate the field. These properties suggest an elongated shape to the particles of V_2O_5 . Some of the preps. could not be examd. under the ultramicroscope; the smallest of the particles appeared to glitter and moved about so rapidly and irregularly that they could not be followed. If the sol was pptd. with KCl, washed, and reprecipitated several times the particles became larger. In a sol which had been 3 times precipitated the particles appeared about 10 times as long as broad and were in rapid Brownian movement. Attempts to ppt. a cryst. solid from the sol were without success; a bulky spongy flock was formed, and a somewhat more concd. sol set to a jelly. The following picture of the sol is suggested to explain its optical behavior: if the sol is not in motion the usual Brownian movement is observed and on account of its unordered character no double refraction is to be expected. If, however, some directed motion is set up, the particles rub against each other, their longest axes are set in the line of the motion, and the sol loses its isotropic nature and becomes double-refracting. A section cut from the sol may be considered as having a space lattice somewhat similar to a plate from an optically mono-axial crystal, the long axis of the sol particles coinciding in direction with the optical axis. If plane-polarized light is allowed to fall on the sol while it is in a streaming motion and the liquid is viewed between crossed nicols the field will remain dark when the elec. vector of the polarized light is parallel or perpendicular to the optical axis. But if the elec. vector is at an angle of 45° a component of the vector passes through the sol (considered as a crystal) to the nicol, and the field becomes bright; the same would be true for any other angle. This was found to be true for V_2O_5 sols. The question is discussed as to what can be considered an amorphous condition in the light of these expts.

E. B. MILLARD.

Double refraction of vanadium pentoxide sols. H. DIESSELHORST AND H. FREUNDLICH. *Physik. Z.* 16, 419-25(1915); cf. preceding abstract.—If V_2O_5 sol is allowed to flow between crossed nicols in convergent light parallel to the line connecting the nicols, an image of a crossed-axis with concentric rings is obtained. By the use of a quarter-wave mica plate it was shown that the V_2O_5 sol when flowing between the prisms behaved like a mono-axial crystal. If the V_2O_5 sol is allowed to flow through a prismatic tube with a triangular cross section and this is used as a prism to decompose spectrum lines, the red H line is decomposed into 2 oppositely polarized lines when a concd. V_2O_5 sol is used. This extraordinary radiation is strongly refracted, corresponding to a positive double refraction, *i. e.*, its elec. vector vibrates parallel to the direction of flow of the sol and therefore to the long axis of the particles. If a dil. sol is used there is only a broadening of the line. It was previously shown that the extraordinary radiation was more strongly absorbed by the V_2O_5 sol than the ordinary; this is in harmony with the rule of Babinet, according to which in colored doubly refracting media those rays are most strongly absorbed which are most slowly propagated and therefore most strongly refracted. Some of these phenomena may also be observed with old $Fe(OH)_3$ sols, but the action is much fainter. The similarity between the swarming in an anisotropic melt and the V_2O_5 particles has already been mentioned, and it was to be expected that mechanical directing of the axes (stirring) would have the same effect, as has been shown for *p*-azoxyanisole and *p*-azoxyphenetole. It is possible that in anisotropic melts there are very viscous glassy mol. aggregates, in which the atoms are not at the points of a space lattice. An amorphous solid is also possibly not isotropic.

E. B. MILLARD.

Willard Gibbs' adsorption coefficient. A. W. PORTER. *Trans. Faraday Soc.* 11, 51-2(1915).—A mathematical proof (in outline) of Gibbs' adsorption theorem, which is extended to strong solutions. E. B. MILLARD.

Nonideal solutions. The activity of a difficultly soluble component. E. K. STRACHAN. *J. Am. Chem. Soc.* 38, 626-32(1916).—The simplest case of a nonideal soln. consists of a solid of only moderate soly. dissolved in a normal liquid forming a mixt. in which the number of mol. species is equal to the number of components. Calcns. are based on solns. of I in CCl_4 , CS_2 , and CHBr_3 . The partial pressure of the moderately sol. component has been calcd. by combining the soly. data with those for the sublimation pressure, and reducing the vapor pressures to a single temp. by means of the Clausius equation. The partial soly. of a difficultly sol. component of a truly nonideal soln. can be expressed by the relation $p = (N/N_s)p_0 + C(N_s - N)N$, in which p is the partial pressure of the solute when its mol. fraction is N , p_0 is the vapor pressure of the max. solute and N_s its mol. fraction in a satd. soln. C is a const. approx. inversely proportional to the square of the soly. E. B. MILLARD.

Theory of acidimetric indicators. R. WEGSCHEIDER. Univ. Vienna. *Z. physik. Chem.* 90, 641-80(1915).—A theory for the color transformation of indicators has been developed, on the ground that the undissociated compds. and similarly constituted ions are similarly colored, and that the color transformation depends upon a change in constitution. Formulas are given for the content of the soln. with respect to free acid or free base for definite concns. of H ions and indicator, for the H-ion content at the point of neutralization for strong acids and bases, and for the indicator concn. By means of these formulas, the exact point of neutralization may be obtained in titration. Some unicolored indicators behave as ideal indicators (those in which the one form appears only in an ionized, the other only in an un-ionized form), others as non-ideal. With ideal indicators, the sensitiveness increases continuously with the indicator concn. while, on the other hand, with non-ideal indicators a max. sensitiveness is associated with a definite concn. of indicator. The dissociation const. and the apparent dissociation const. of the colored form serve for the calcn. of all phenomena. Both these consts. can be ascertained. Better results are obtained by using an indicator acid that is colored in alk. soln. or an indicator base that is colored in acid soln. than by using an indicator acid that is colored in acid soln. or an indicator base that is colored in alk. soln. Two-colored indicators can behave differently. Their behavior may be ascertained from the apparent dissociation const. Ideal and non-ideal two-colored indicators behave alike. The collective equil. consts. of a non-ideal indicator (dissoc. consts. of both forms and transformation const.) can only be detd. by the usual chem. and optical methods, when spectral regions can be found in which only one form is absorbed. The proof that this condition is fulfilled is difficult to ascertain in the case of two-colored indicators. H. JERMAIN CREIGHTON.

Partition coefficients of hydrogen peroxide between water and certain organic solvents. J. H. WALTON AND H. A. LEWIS. *J. Am. Chem. Soc.* 38, 633-8(1916).—About 15 cc. of H_2O and the same amt. of the organic liquid were placed in glass-stoppered bottles with the desired amt. of H_2O_2 and rotated in a thermostat for about an hour. Then samples were withdrawn and analyzed either by titration with KMnO_4 or, in cases in which this substance oxidized the organic liquid, gasometrically by means of MnO_2 catalyzer. Expts. were made at 25° with the following liquids: EtOAc , $\text{iso-C}_4\text{H}_9\text{OH}$, amyl acetate, acetophenone, Et_2O , aniline, phenol and quinoline. When a soln. of H_2O_2 is shaken with the last-named substance more than half of the H_2O_2 is removed. Organic solvents which dissolve H_2O will also dissolve H_2O_2 . H_2O_2 does not undergo association in the solvents studied. The quinoline soln. is not a simple

one, but probably consists of a compd. of the solvent and H_2O_2 in equil. with H_2O .
E. B. MILLARD.

Studies of the vapor pressure of solutions. Lowering of the vapor pressure of water produced by dissolved potassium chloride. B. F. LOVELACE, J. C. W. FRAZER AND E. MILLER. *J. Am. Chem. Soc.* 38, 515-28(1916); cf. *C. A.* 9, 403.—The original app. has been changed to include a new thermostat const. to 0.001° for periods of 12 hrs., a device for stirring the soln. and solvent in the vacuum, and a more sensitive McLeod gage. Actual observations were made only after the air pressure in the McLeod gage was less than 0.0001 mm.; under these conditions the vapor pressure lowering was const. to 0.001 mm. for days. Solns. of KCl of 9 concns. between 0.2 and 2.0 M at 20° were studied. Changes of concn. of the solns. during the removal of dissolved air and the measurement of the vapor tensions were negligible. The mol. lowering of the vapor tension was the same for all concns. investigated (cf. Tower and Germann, *C. A.* 9, 403). The reason for this cannot be detd. until the rigid applicability of Raoult's law has been tested for some nonelectrolyte over the same concn. This is to be done as soon as possible.
E. B. MILLARD.

Difficulties in van Laar's theory of the vapor pressure of binary mixtures. R. T. LATTY. *Trans. Faraday Soc.* 11, 118-20(1915).—Mathematical formulas are derived for the condition under which the P/x graph will pass through a max. or a minimum and for conditions of partial miscibility at one temp. and complete miscibility at another temp. From calcns. on the vapor pressure curve of MeEtCO and H_2O it is shown that the formula is not only inconsistent with the observed effects of temp., but that it does not agree with exptl. facts when comparison is made at const. temp. R. B. M.

Viscosity coefficients of mixtures of helium and hydrogen. A. GILLER. *Ann. Physik* 48, 799-837(1915).—New detns. have been made of the viscosity coeffs. of air, He and H. Viscosity coeffs. of mixts. of He and H have been detd. at 0° , 15° and 100° . Between 0° and 100° the change of the viscosity coeffs. with temp. can be expressed by Sutherland's law for the mixts. investigated. The change of the viscosity coeffs. with the compn. of the mixts. can be expressed by Puluij's formula. H. J. C.

Study of binary mixtures. I. Densities and viscosities of mixtures containing phenol. ARTHUR BRAMLEY. *J. Chem. Soc.* 109, 10-45(1916).—Mixts. of $\text{C}_6\text{H}_5\text{OH}$ with C_6H_6 , $\text{C}_6\text{H}_5\text{Cl}$, $\text{C}_6\text{H}_5\text{NO}_2$, $\text{C}_6\text{H}_5\text{NH}_2$, $\text{C}_6\text{H}_5\text{N}(\text{CH}_3)_2$, *p*-toluidine, $(\text{C}_6\text{H}_5)_2\text{NH}$, $\text{C}(\text{C}_6\text{H}_5)_2\text{NH}$, $\text{C}_6\text{H}_5\text{N}$, phenetole and acetone and of $\text{C}_6\text{H}_5\text{NH}_2$ with phenetole at various concns. were studied at several temps. Viscosities were detd. in 3 pairs of Ostwald viscosimeters, and d 's in 10 cc. pycnometers. Mixts. contg. $\text{C}_6\text{H}_5\text{OH}$ have lower viscosities than correspond to the mixt. rule when the 2nd liquid is "indifferent," and when a compd. is formed in the mixt. the viscosity is generally higher than that demanded by the mixture rule. Deviations are due to the acidic nature of phenol. Phenetole and aniline give mixts. whose viscosity curves are convex toward the compn. axis; the phenol mixts. are concave toward this axis. The position of the max. point on the viscosity curves generally varies with the temp., and therefore gives little indication of the compn. of any compd. which might be present. The conclusions are not in harmony with those of Denison (*C. A.* 7, 925). Peculiarities in the curves may be due to the unequal thermal dissociation of phenol and the compds. formed with changing temp.
E. B. MILLARD.

Equilibrium between mucic acid and its lactones. W. A. TAYLOR AND S. F. ACRRE. *J. Phys. Chem.* 20, 118-20(1916).—This equil. was detd. in connection with the larger problem of the mechanism of the reactions involved in the oxidation and reduction of sugars and their derivs. Mucic acid solns. containing an excess of solid mucic acid were prepd. at room temp., at 30° and at 100° , then placed in a const.

temp. bath at 25°. The acid was detd. by titration with 0.1 *N* alkali at 0°, the lactone by adding an excess of standard alkali, boiling a few min. and titrating the excess with 0.1 *N* HCL. Equil. is established in from 1440 to 2880 hrs. (the longer time was required for the soln. prepd. at 100° which showed supersaturation) and at equil. there are about twice as many lactone as carboxyl groups in the soln. Further investigation will be instituted to det. whether the lactone is the mono- or dilactone and to learn whether acids catalyze these changes by the H ion, the nonionized molecule, or both.

H. I. MATTILL.

The kinetic interpretation of osmotic pressure. P. EHRENFEST. *Ann. Physik* 48, 369-74(1915); cf. *C. A.* 9, 1866.—A mathematical paper. H. J. C.

Entropy constant of diatomic gases. MAX PLANCK. *Verh. deut. physik. Ges.* 17, 418-9(1915).—Mathematical. An expression has been derived which is exactly the same as that of Tetrode (*C. A.* 9, 2020), though derived in an independent manner. This agreement is support for the Nernst heat theorem. E. B. MILLARD.

Heat of neutralization and the quantum theory. A. HEYDWEILLER. *Ann. Physik* 48, 681-92(1915).—From considerations of Planck's equation for the energy of a system composed of a definite number of linear oscillators with a definite frequency at a definite temp. it was shown that the heat evolution of a chem. reaction at ordinary temp., in which only one electron in the mol. is altered in its method of linking and its vibration frequency, is proportional to this change of the properties of the electron. The proportionality const., if the heat is expressed in ergs per mol., is $Nh/2$, where N is Avogadro's number and h is the h of Planck's theory. The exptl. material consisted of detns. of d., n , and elec. cond. of the hydroxides of Li, Na, K and Rb in H₂O at 6 or 8 concns. This material is mathematically discussed in a form not suited to brief review. The calcd. results agree with the exptl. in order of magnitude, but do not constitute a confirmation of the theory. There is, however, nothing to indicate a refutation of the theory. E. B. MILLARD.

Heat conductivity of neon. E. BANNAWITZ. *Ann. Physik* 48, 577-92(1915).—A wire was stretched along the axis of a cylindrical glass tube contg. the gas and immersed in a water bath, and the wire was heated by a measured (direct) current. The value of resistance (detd. while the heating is in progress) and current together determine the heat conducted and radiated from the wire through the gas to the glass vessel. Parallel expts. conducted in a vacuum eliminated the radiation; the heat conducted was detd. from the rise in temp. of the surrounding bath. At 0° the mean value detd. was $k_0 = 0.0001091$ (g./cal.)/(sec./cm.), and the temp. coeff. (mean value) was 0.00259. The corresponding temp. coeffs. for air, A, and He are 0.00253, 0.00260 and 0.00318, respectively. E. B. MILLARD.

The freezing point of benzene as a fixed point in thermometry. J. MEYER. *Z. physik. Chem.* 90, 721-2(1915); cf. *C. A.* 8, 3524.—M. cites a number of objections to the use of C₆H₆ for the standardization of thermometers. H. J. CREIGHTON.

The moving of boundaries in electrolytic solutions. M. V. LAUR. Frankfurt a/M. *Z. anorg. allgem. Chem.* 93, 329-41(1915).—The theory of moving boundaries in electrolytic solns. was developed by Kohlrausch and Weber on the assumption of complete ionization. This paper is a rigorous mathematical development of the theory for more concd. solns. in which the electrolytes are incompletely ionized. For the compd. $A_\mu B_\nu$, assuming the mobilities U and W to be independent of the concn., the speed of the moving boundaries is given by the expression: $\Delta x/\Delta t = UI/m_\nu F(U + W)\alpha$, in which I is the current density, m the valence of ion A , α the total concn. of $A_\mu B_\nu$. It will be observed that this expression differs from that derived by K. and by W. in the concn. term; the total concn. replacing the ion concn. GEORGE W. MORF.

Conduction of the electric current in ethyl ether. J. FASSBINDER. Univ. Greifswald. *Ann. Physik* 48, 449-80(1915).—The dissociation of pure Et_2O is exceptionally small. The cond. values previously found can only be explained by the presence of impurities. Small quantities of impurities are not dissociated by Et_2O . The ions which carry the current are produced chiefly at the electrodes, where the solute is absorbed and ionized. The elec. field then tears these ions from the electrodes. Consequently, the current-strength increases only with the strength of the elec. field; it is independent of the vol. of the liquid, *i. e.*, of the distance which the electrodes are apart. It depends to a large degree, however, upon the quantity of solute contained in the Et_2O . Pt electrodes absorb the solute to but a slight extent and give up the ions readily from their surface. On the other hand, Ag electrodes absorb the solute to a large extent and hold the ions on their surface. H. JERMAIN CREIGHTON.

The electric conductivity of tetrazole and derivatives at various temperatures. E. OLIVERI-MANDALÀ. *Gazz. chim. ital.* 45, I, 303-6(1915).—In a preceding paper (C. A. 9, 884) it was shown that the temp. coeff. of tetrazole and the corresponding amide, calcd. from elec. cond. data, increases with increasing temp. and this increased ionization was interpreted as due to the production of the more acid form arising by the passage of H from 1 N atom to the other. This explanation seemed justified by the behavior of tetrazole, the 2 isomeric ethers of which were obtained by the action of alkyl iodides on the Ag salt and by the direct action of diazomethane. The study has been continued with the use of a larger amt. of tetrazole and extended to another deriv.: ethyl tetrazolecarboxylate (a), $\text{N:N.N.NH.CCO}_2\text{Et}$. The temp. coeffs. of

tetrazole $(u_h - u_l)/(h - l)$ for dilns. of 32, 64, 128, 256 for 0-10° are 0.162, 0.222, 0.287, 0.392, resp.; for 10-20°, 0.180, 0.246, 0.343, 0.465; for 20-30° 0.201, 0.266, 0.355, 0.499. The dissociation consts. for dilns. of 32, 64, 128, 256 for 0° are 0.0000092, 0.0000089, 0.0000085, 0.0000079; for 10° 0.000012, 0.000011, 0.000010, 0.0000098; for 20° 0.00014, 0.000013, 0.000013, 0.000013; for 30° 0.000018, 0.000017, 0.000016, 0.000015. The limit values of the mol. cond. of (a) were calcd. from the data given according to Kohlrausch's law $[\mu_{\infty RH} = \mu_{\infty RNa} + (\mu_{\infty HCl} - \mu_{\infty NaCl})]$ and were as follows at 0°: μ_{∞} for (a) is 241.51, at 10° 299.88, at 20° 356.76, at 30° 410.04. The dissociation consts. for dilns. of 32, 64, 128, 256 for 0° are 0.000030, 0.000029, 0.000028, 0.000027, resp.; for 10° 0.000038, 0.000037, 0.000037, 0.000033; for 20° 0.000056, 0.000056, 0.000055, 0.000048. E. J. WITZEMANN.

Arcs in gases between non-vaporizing electrodes. G. J. M. MACKAY AND C. V. FERGUSON. *J. Frank. Inst.* 181, 209-16(1916).—A preliminary paper on arcs from hot W in atms. of H, A, N, and air. Enclosed arcs were constructed which acted as rectifiers of a. c., carrying 10 to 20 amps. with such slight deterioration of the W that a life of many hundred hours could be obtained. The electrodes operate at 2600° to 3200° K., and there appears to be no more loss of metal than can be accounted for by the normal rate of evapn. of W at these temps. If the pressure of the surrounding gas is several cm. there is no trace of cathode sputtering which occurs so violently at lower pressures, on account of a decrease in the high cathode-drop. Curves are given showing the characteristics of the arcs in the various gases. Rapid vaporization and chem. reaction at the electrode surfaces are merely incidental to the phys. phenomena involved, which are undoubtedly the most important. A more detailed report is to be given later. E. B. MILLARD.

Application of the theory of allotropy to electromotive equilibria. II. The passivity of iron. A. SMYTH AND A. W. H. ATEN. Univ. A. Chem. 90, 723-43(1915); cf. C. A. 8, 2514; 9, 1140.—

polarization and the passivity of iron resulting from chem. means or through anodic polarization are described. Several theories are discussed, and it is shown that the primary phenomenon of the passivity of iron cannot be explained by the oxidation theory. The O charging and the contingent oxide formation are secondary phenomena. It is emphasized that the passivity has its seat in the surface of the metal, and, in accordance with the theory of allotropy, it is shown that the appearance of the passivity of iron, brought about either by anodic soln. or by the action of chem. reagents, as well as the transition from the passive condition to the active, and the abnormal cathodic polarization may be explained from the same point of view. The appearance of polarization is not due to the fact that the heterogeneous equil. between the metal and the soln. is slowly established, but to the fact that the metal is forced to dissolve more quickly, so that the inner equil. may be established, whereby an ennobling of the surface of the metal occurs. A strong support for the new conception is to be found in the fact that Fe in a soln. of $\text{Fe}_2(\text{SO}_4)_3$ exhibits a more positive potential than in a soln. of FeSO_4 of the same concn. It has been shown that the activation curve refers to a discontinuity in the mixing proportions of the pseudo components. The abnormal cathodic polarization has been discussed and explained in the light of the theory. H. J. CRIGHTON.

The true nature of the so-called adsorption potential. R. BEUTNER. *Elektrochem. Z.* 22, 177-82 (1915); cf. C. A. 8, 2300.—The charge on oil drops in H_2O is affected by the addition of salts. This is not caused by any action of the surface charge on the ions but depends upon the division of the salt between the oil and the H_2O , a certain dissociation of the salt in the oil and the application of the osmotic law for the potential difference between oil and H_2O . This law is analogous to Nernst's law for electrode potential. An approx. measure of the proportion of salt in the oil and in the H_2O is obtained by conductivity measurements which show that the relative proportion is dependent upon the chem. nature of the salt. W. E. RUDER.

Overvoltage. C. W. BENNETT AND J. G. THOMPSON. *Cornell. Trans. Am. Electrochem. Soc.* 29, adv. copy, 24 pp. (1916).—Heretofore overvoltage has been considered from the relative standpoint, using an arbitrary standard. When H overvoltage is considered to be the difference between the voltage required to liberate H at the surface of a platinized cathode, and the voltage required at the surface of the metal in question, the values obtained vary, according to whether the point of gas evolution or the break in the voltage current curve is taken. The values also increase with an increase in c. d. Le Blanc considers H overvoltage to be the excess of back e. m. f. generated at the electrode, over that at a platinized Pt electrode. Metals have definite overvoltages, but none of the definitions of overvoltage apply to metal overvoltage. In the general sense, overvoltage may denote the excess of back e. m. f. of the system (cathode or anode) over the e. m. f. of the system consisting of the final product obtained (at anode or cathode) in the soln. used. Thus Zn overvoltage would be the excess of the back e. m. f. of the system, $\text{Zn} \longrightarrow \text{Zn soln.}$, during electrolysis, over the e. m. f. of the reaction, $\text{solid Zn} \longrightarrow \text{dissolved Zn ion}$. The overvoltage represents, then, the excess energy required to form a substance, over that given by the resolution of the substance formed to the original state, and measures the irreversibility of the process. The various theories which aim to explain overvoltage are considered, but none of them will afford an explanation of metal overvoltages, as well as gas overvoltages. If H is considered it is found that there is a form intermediate between ion and gas, which is more reactive than either, and which is a stronger reducing agent than Zn. This active H is produced at the cathode during electrolysis of an acid, during soln. of a metal in an acid, by action of Ra emanations, by action of electrical discharges, and by photochemical effects. In a similar manner, active O is formed from the dissolved ion irreversibly, and it will oxidize substances which

are not affected by H_2O_2 or ozone. The reactions involving the active products are not reversible. H_2 gas forms H^+ ion by first taking on an elec. charge. This reaction generates a certain qu with a definite intensity, and the total energy is the product of the t direction H gas is not formed until a concn. of active H is reached than, equil. requires. When equil. is exceeded, energy of a greater required to carry out the formation of gas quickly. The total volt is that occasioned by the active H present, and the excess of bac voltage, is that occasioned by the active H present in excess of process is not reversible by the energy, or heat of formation of acti as it is present above equil. In the case of a metal, atomic metal, and metal, is the unstable, intermediate form. With Zn, the intermedia to be more strongly reducing than massive Zn. These intermedia to be sufficiently active to account for the irreversibilities found v the change from atomic to molecular material is rapid, then the low, and any influence which can affect the speed of this reaction, voltage. Any condition which can increase the concn. of the int will increase the overvoltage. SH

The dependence of the photoelectric charging potential upon GEHRCKE AND L. JANICKI. Charlottenburg. *Ann. Physik* 47, (presence of H, He and H_2O vapor retards the appearance of a positive In a high vacuum the charging potential is +2.3 v. Expts. with gave no indication of an effect depending upon the nature of the is explained by assuming that the fastest photoelectrons result t itself, but from the H occluded therein. H. JER

Optical investigations on the constitution of inorganic acids K. SCHAEFER. *Z. Elektrochem.* 21, 181-91(1915); cf. *C. A.* 9, 416 of the absorption spectra of the O acids of S, Cl and N shows that acid differs from that of the corresponding salt. In the case of s undissociated mol. and ions differ. This is particularly advantag the study of electrolytes, as it makes it possible to follow the con the neutral part of the electrolyte.

The natural optical activity of liquids and gases. M. BOR 251-8(1915).—In "Dynamik der Kristallgitter" Teubner, Born sl cular double refraction exhibited by a crystal when light passes thro tion of the optical axis may be related to the grating structure o present paper treats of the optical activity of liquids and gases in manner. The mol. is considered as a system of mechanically gro possessing a certain mass and charge. The simplest optically ac to be an asymmetric tetrahedron. The discussion is entirely (

The Doppler effect of canal rays in argon. K. FREIDERSDO *Ann. Physik* 47, 737-62(1915).—Many of the results obtained by baum (*C. A.* 8, 1382) in the region 4300-4000 Å. units, have be region 4965.4-2884.1 Å. units. The lines of the red A spectrum univalent ions, and those of the blue to bivalent or polyvalent ion the particles of different valence is established through neutraliz The number of univalent ions decreases with increasing voltag zero at 42000 v. In addition to bivalent and trivalent ions, t appear in A canal rays at high voltages. H. JER

Studies in catalysis. III. Preliminary measurements of the infra-red absorption spectra of hydrogen chloride, potassium chloride and methyl acetate in aqueous solution. R. H. CALLOW, W. C. McC. LEWIS AND G. NODDER. *J. Chem. Soc.* 109, 55-67 (1916); cf. *C. A.* 9, 262, 1420.—A radiomicrometer of the H. C. Jones type has been used to measure the infra-red absorption of HCl, KCl and MeOAc over the range 1 to 2.1μ . The solutes exhibit remarkably similar behavior in respect to the position of the absorption bands which occur at 1.12μ , 1.55μ , and 2.1μ (approx.), and thus correspond to the bands of H_2O itself, with a slight displacement in the direction of the longer wave length. The behavior observed is perhaps due to the formation of additive compds. between the solute and the solvent. HCl possesses a much greater absorptive power than KCl in the short infra-red region. This is in agreement with the radiation theory of homogeneous catalysis, according to which a positive catalyst is one which increases the radiation d. at certain points of the short infra-red region. It is known that the existence of an absorption band increases the radiation d. abnormally for wave lengths below the band and diminishes it for wave lengths above the band. IV. Stoichiometric and catalytic effects due to the progressive displacement of one reactant by another in the "acid" hydrolysis of methyl acetate. R. O. GRIFFITH AND W. C. McC. LEWIS. *Ibid* 67-83.—Detns. of the velocity of hydrolysis of MeOAc by N , $0.5 N$ and $0.1 N$ HCl and $0.5 N$ CCl_3COOH have been carried out with varying initial concns. of the ester. The unimol. consts. (after correction for the reverse reaction) were const. in each expt., but their values depended on the initial concn. of the system, the value rising with the concn. of the ester. Change in the dissociation of the catalyzing acid as more ester was added, and the accompanying change in catalytic activity, could not account for the change of the consts. If the reacting substance is considered to be an ester- H_2O additive complex, the degree of dissociation of which decreases as the water concn. decreases, the variation in the reaction velocity can be explained. In other words the H_2O is considered as a negative catalyst in virtue of its high dissociating power at the same time as it acts stoichiometrically. The equil. const. for the reaction between MeOAc and H_2O in the presence of HCl of a concn. less than N was 4.6. E. B. MILLARD.

Single-line spectra of magnesium and other metals and their ionizing potentials. J. C. McLENNAN. *J. Frank. Inst.* 181, 191-207 (1916); cf. *C. A.* 10, 146.—Radiation from Mg vapor traversed by electrons has been investigated by the method of McL. and Henderson (*C. A.* 9, 3155). If the electrons bombarding the vapor possess energy lying within a certain range (not yet definitely detd., but covering a portion of the ranges for Hg, Zn and Cd) corresponding to potentials of 5 or 10 v., Mg vapor is stimulated to the emission of a single-line spectrum of wave length $\lambda = 2852.22 \text{ \AA}$. The absorption spectrum of non-luminous Mg vapor contains a band at $\lambda = 2852.22 \text{ \AA}$ and one at $2073.36 \text{ \AA}$. As these lines are the first members of Paschen's series $\nu = 2$, $p_2 - m$, S and $\nu' = 1.5$, $S - m$, P , resp. (*C. A.* 6, 828), the absorption spectrum of Mg vapor has been shown to be analogous to the spectra of the vapors of Hg, Zn and Cd. The single-line spectra of Ca, Sr, Ba and Tl vapors should have the wave lengths $\lambda = 4226.91 \text{ \AA}$, $\lambda = 4607.52 \text{ \AA}$, $\lambda = 5535.69 \text{ \AA}$ and $\lambda = 5350.65 \text{ \AA}$, resp. The ionizing potentials for these elements were Hg 4.9, Zn 3.96, Cd 3.74, Mg 4.28, Ca 2.89, Sr 2.65, Ba 2.24, Tl 2.28 v. If Bohr's theory (*C. A.* 8, 1906; 9, 3016) affords an explanation of the origin of single-line spectra, then Frank and Hertz, and also Newman must have placed a wrong interpretation on their exptl. detns. of the ionization potentials of Hg atoms. Also in *Proc. Roy. Soc. London (A)* 92, 305-12 (1915). E. B. M.

Observations of the effect of the electric field upon spectral lines. V. Fine decomposition of the hydrogen series. J. STARK. Aachen. *Ann. Physik* 48, 193-209 (1915); cf. *C. A.* 8, 2103.—The lack of sharpness of H lines decomposed by the elec.

field raises the question as to whether or not the number of the components would not be increased by stronger decompn. In the present investigation, elec. static fields of 104,000 v./cm. instead of 30,000 v./cm. have been employed. As in previous expts., the light intensity is considerably increased. The inhomogeneity of the potential field in the canal ray tube produces bent lines. This permits the differentiation of the decompn. components from foreign lines. The directions of the canal rays and the elec. field are opposed. As expected, the fine decompn. gives more components than the coarse decompn. VI. Polarization and strengthening of a series. *Ibid* 210-35.—On the supposition that the carrier of a series line possesses polarity and anisotropy of the emission at the at. axis, S. expects a polarization of the series line which need not be connected with a splitting. Three lines of the 3rd Li side series have been investigated, and it has been found that in the elec. field polarization without splitting occurs. The magnitude of the strengthening of the 3rd Li side series is remarkable (cf. C. A. 10, 556). Phenomena similar to those observed for Li have been found in the case of He.

H. JERMAIN CREIGHTON.

Spectra of ruthenium, columbium and tantalum. E. PAULSON. *Physik. Z.* 16, 352-4(1915); cf. C. A. 9, 2029.—In an earlier paper an arrangement has been given of 548 lines in the Ru spectrum which group themselves into 65 more or less complete groups of 18 lines each. As an extension of the work 91 other lines have been added to this system. In the Ta spectrum many pairs of lines with a difference in wave length of 237.00 have been found, and in the Cb spectrum there are 5 lines repeated at intervals. The calcns. are based on the measurements of Exner and Haschek.

E. B. M.

A new line series in the helium spectrum. J. KOCH. Gothenburg. *Ann. Physik* 48, 98-108(1915).—In strong elec. fields there appear new He lines, which are related to a parallel chief series. Their limit is the same as that of the side series of univalent He.

H. JERMAIN CREIGHTON.

Physical photometer in theory and practice. W. W. COBLENTZ. *J. Frank. Inst.* 181, 233-41(1916); cf. C. A. 9, 3162.

E. B. MILLARD.

The influence of magnetization on the direct current resistance of graphite in the direction of the principal axis. G. E. WASHBURN. Bosscha Lab. *Ann. Physik* 48, 236-50(1915).—The investigation covers samples of Ceylon, Mexican and American graphite. The specific resistance in the direction of the principal axis is from 80 to 90×10^{-4} ohm/cm. while at right angles to this axis it is about 0.80×10^{-4} ohm/cm. This ratio of about 100 is, perhaps, the greatest cond. difference observed for any one substance. When the samples were placed in a magnetic field making an angle with the principal axis, the relative change in the resistance ($\Delta R/R$) parallel to the principal axis was found to be equal to the relative change when the sample was placed perpendicular to the field plus a term proportional to the component of the field in the direction of the axis. The ratio of the resistance change when the axis is parallel to the field to the change when the axis is perpendicular is about 7 to 1. For a field of 30 kilogauss and the axis parallel to the field the increase in resistance is about 80%.

O. A. R.

Alcoholysis of salts. H. GOLDSCHMIDT. *Z. Elektrochem.* 22, 11-5(1916).—Calcns. are given which show that the addition of H_2O to an alc. soln. results in a decrease in the concn. of free base and acid, if the salt is alcoholized, together with an increase in concn. of OH^- and a decrease in the alcoholysis of the salt. Expts. have been made on the elec. cond. of mixts. of bases and acids at several concns. in abs. alc. In one series of expts. equiv. amts. of aniline and salicylic acid were used; in another series a const. excess of 0.1 equiv. aniline was present. Other expts. were made with aniline and different acids, and finally a series in which H_2O in various amts. was added

to the alc., with aniline or toluidine and several acids. Secondary and tertiary bases are much more alcoholized than primary bases, i. e., they are weaker than the primary ones; but in H_2O the opposite is the case, the tertiary being much the strongest. In these cases the alcoholysis is much more strongly influenced than it should be according to the equations developed, since the affinity const. of the base is changed by the addition of another solvent. Addition of H_2O to alc. solns. has an effect that is the same as the catalytic effect of an acid. The assumption that the negative catalytic effect of H_2O in a H^+ catalysis is due to a distribution of the H^+ between the H_2O and the other solvent is supported by these expts.

E. B. MILLARD.

The chemistry of amorphous solids. W. H. LEWIS. *J. Soc. Chem. Ind.* 35, 12-5 (1916).—Some generalizations giving the relations of plasticity of a material to its mol. size. The mol. of an amorphous solid may be written V_n , V being a small unit ($C_6H_{10}O_5$ for cellulose, C_4H_8 for rubber) and n an integer differing in value under different conditions but not capable of being made to assume any value since the final aggregate is probably formed by a succession of condensations. Plasticity and chem. and physical inertness decrease with increased mol. size and with falling temp. Solvents and mechanical manipulation by decreasing the size of the aggregates tend to increase plasticity. The "setting" of plastic bodies is accomplished by lowering the temp. (in glass), by increasing the size of the mol. (tanning hides, vulcanizing rubber, which increases V rather than n), by chem. conversion into less plastic materials (ceramics, cement), by removal of a solvent, by increasing n (bakelite).

H. I. MATTILL.

The distillation of organic acids with water. ORCHSNER DE CONINCK AND A. RAYNAUD. Univ. Montpellier. *Rev. gén. chim.* 18, 134-5 (1915).—Separate mixts. of 5 cc. acid and 25 cc. distd. water were slowly distd. Five cc. portions of the distillates were titrated with 0.1 N KOH. The amts. of formic and acetic acids in the resp. fractions increased regularly, propionic acid very regularly, butyric and isobutyric very irregularly.

L. H. CHERNOFF.

Chemistry and technology from original historical scientific writings. EDMUND O. VON LIPPMAUN. *Chem. Ztg.* 40, 3-5, 26-8, 48-50 (1916).—A review of theories, recipes and processes in the 10th-12th centuries, with a bibliography of 115 references.

Measurement of dielectric losses with the cathode ray tube. H. W. FISHER, et al. *Proc. Am. Inst. Elec. Eng.* 35, 21-34 (1916).—Discussion of Minton's paper (cf. *C. A.* 9, 2735).

C. G. F.

The existence of a polonium-hydrogen compound. ROBERT W. LAWSON. Radium Inst., Vienna. *Monatsh.* 36, 845-52 (1915).—During a detn. of the ionization over the range of α -rays from Po in H abnormally rapid increases in the ionization were noted when no solid window intervened between the Po and the ionization chamber. This was not due to a volatility of the Po itself nor to a transfer of a part of the Po along with the recoil atoms of Ra G. It is best explained by the assumption that a hydride,

similar to H_2S and H_2Se , is formed, which diffuses into the ionization chamber. The compd. is immediately destroyed by small amts. of air, probably through the activating action of the α -rays. Such a hydride would explain the observation of Hévesy and Paneth (*C. A.* 8, 13) that Pt and Pd have a very high sp. absorptive power for Po.

G. L. WENDT.

The new element brevium and attempts to discover its isotopes. O. H. GÖHRING. *Dissertation*, Techn. Hochschule, Karlsruhe, 1914; *Neues Jahrb. Min. Geol.* 1915, II, Ref. 15.—A review of previous work by Fajans and Göhring (cf. *C. A.* 7, 3916; 8, 297). The newly discovered element known heretofore as $U X_2$ has received the name *brevium*. Attempts to discover the mother substance of Act in pitchblende showed that it is very doubtful whether Act is formed by an α -ray transformation.

E. A. TSCHUDY.

Radiography of crystals. F. STRÖBER. *Bull. soc. franc. min.* 37, 76-97(1914).—A general discussion of recent work on this subject, with suggestions as to possible new interpretations of certain phenomena, especially secondary rays. The results obtained with amorphous substances may be interpreted as due to inclusions of minute crystals, and it is pointed out that there is a wide field for study of substances whose character is intermediate between cryst. and amorphous.

E. T. WHERRY.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Recent advances in theoretical electrochemistry. ANON. *Elektrochem. Z.* 22, 213-8(1916).—A review of recent literature.

W. E. RUDER.

Electricity. Fundamental units. F. E. SMITH. London. *National Phys. Lab.* 1914-5, 40-4.—Abs. measurements of resistance showed with the Lorenz app. one international ohm = 1.00052 ohm (10^6 C. G. S. units) and no change from the test of the previous year. With hermetic seal, coils showed a change of less than one part in 100,000 except in a 10,000 ohm coil. Without the seal the changes are greater. In the Weston cell, hydrolysis of Hg_2SO_4 caused presence of complex ions. Acidity detns. are difficult. Tests on solubilities, conductivities, etc., of Hg_2SO_4 and $CdSO_4$ with and without acid were tried. Results show a decrease in e. m. f. if the depolarizer is partially hydrolyzed, the rate depending upon the extent of the hydrolysis in the layer of salt next to the Hg surface. The formation of complex ions leads to an increase in e. m. f., but the Hg ion concn. diminishes rapidly near the surface of the Hg. Compass and optical glass tests were satisfactory.

W. H. BOYNTON.

Power situation at Niagara Falls. F. A. LIDBURY, et al. *Mel. Chem. Eng.* 14, 239-41; *Elec. World* 67, 471-2(1916).—Report of a meeting of electrochemists and engineers at Niagara Falls. The shortage of power is seriously hampering the electrochem. industries and through them the industries of the country at large. The urgent need of immediate government support and legislation to relieve the situation was emphasized. A shortage in the supply of Niagara ferro-silicon, ferro alloys, Al, artificial abrasives, etc., would embarrass the industries throughout the U. S. The very important N-fixation works of the American Cyanamid Co. had to be located in Canada for lack of sufficient cheap power in the U. S.

C. G. F.

New war products. ALBERT H. HOOKER. *Trans. Am. Electrochem. Soc.* 29 (advance copy); *Mel. Chem. Eng.* 14, 261-2(1916); *J. Ind. Eng. Chem.* 8, 288(1916).—The number and importance of the electrochem. products made at Niagara Falls

were discussed, and a plan proposed for future development there. The present diversion of water from the falls produces some 50,000 horse power, and water to produce well over 1,000,000 h. p. more could be diverted without injury to the scenic value of the falls. For every 100,000 h. p. diverted, the government should provide that 10,000 h. p. be devoted to the fixation of atm. N. The development of electrochem. industries is an important feature of Germany's efficiency, and in this country, stimulation and organization of chem. manufacturing, and the ability to make new war products, must be the basis of any adequate military preparedness.

SHERMAN EASTMAN.

Thermal efficiency of the electric furnace. W. MCA. JOHNSON. *Proc. Eng. Soc. West. Penn.* 31, 488-98(1915).—Thermal efficiency may be detd. by obtaining the radiation and cond. losses either by direct means or by calcn. from available data, by calcg. the net heat required of the charge, or by detg. the power required to keep the furnace at its working temp. when running on dry slag. In order to increase the efficiency, the smelting rate and the size of the furnace may be increased and its shape made to approach a sphere or cube; in such a case its walls should be made thicker and the outside painted with Al.

W. E. RUDER.

A simple carbon-helix resistance furnace and a photographic temperature recording apparatus. ERNST JANECKE. *Z. Elektrochem.* 21, 439-43(1915).—The furnace consists of a C helix (cf. Arsem furnace) placed vertically in a concentric clay cylinder, the space between the helix and the cylinder being filled with powdered MgO. At the upper and lower end, the C helix is fitted tightly into water-cooled Fe plates to which the terminals of a 110 v. line are connected. The material to be heated is placed in a MgO crucible which sits upon a MgO support. When in operation an atmosphere of H₂ or N₂ is maintained in the furnace. As much as 2 kg. can be melted at a time and a temp. of 1800° is practicable. The temp. recording device consists of a reflecting galvanometer in series with a thermocouple and set up in a dark room in such a way that its mirror reflects a spot of light upon a sheet of photographic paper which is passed before a slit at a const. rate by a motor-driven drum. Cuts and photos are shown.

F. A. STRAUSS.

The electric furnace as a soaking pit in the steel mill. T. F. BAILY. *Iron Age* 97, 311(1916).—Statistics show a current consumption of 60 kw.-hr. per ton absorbed by the metal and 40 kw.-hr. per ton wall loss for hot ingots. Elec. soaking pits can compete with gas-fired pits, and have a non-oxidizing atm. which saves 1-2% of the wt. of the ingot. They occupy 1/3 the space of gas-fired pits of the same capacity, and eliminate ingot surface defects due to scale or oxidation.

W. H. BOYNTON.

The electric furnace in the foundry. R. C. GOSROW. *Met. Chem. Eng.* 13, 882-3(1915).—G. discusses the various points of superiority generally ascribed to the elec. furnace.

W. E. RUDER.

The electric furnace in the foundry. N. PETINOT. *Met. Chem. Eng.* 13, 650 (1915); cf. *C. A.* 9, 2189.—Discussion of W. G. Kranz's paper on this subject. P. does not believe that the elec. furnace so completely reduces Fe that Al, W, Ti added will not disappear but will alloy with the Fe. He always found Al present when added as a deoxidizer but always in the form of Al₂O₃. The great advantage of the elec. furnace as a deoxidizer is doubted if it is still necessary to deoxidize in the ladle.

W. E. R.

Large electric furnace for pig iron. HELFENSTEIN-ENGELHARDT. *Monat. Rundsch.* 7, 110(1915); *Chem. Zeit.* 39(1915); *J. Soc. Chem. Ind.* 34, 1011(1915).—The first furnace of this kind had a capacity of 10,000-12,000 h. p. and was erected in Domnarfvet. It is rectangular in cross-section, and has a permanent cover with holes for the escape of gases and for charging. The av. output was 65 tons per 24 hrs. It consumed 2000 kw.-hr., 300-400 kg. of charcoal and 70 kg. of electrode material

per ton of pig Fe. Up to 70% of unbriquetted fine ore may be used. Costs are said to be lower than for other types of furnaces.

The fixation of atmospheric nitrogen. R. G. SKERRETT (1916).—A general descriptive article. The agricultural and industrial uses of N are stated. The Birkeland-Eyde plants in Norway and the Caro plants in Germany and the Canadian plant of the American Cyanamid Co. are described briefly. The ultimate product of the Scandinavian process is less expensive than that of the German cyanamide process, in which lignite is used. The latter can be converted into urea, which the U. S. imports for making creatine and HNO_3 can also be made from cyanamide. The American Cyanamid Co., which uses the arc process, but its commercial success depends on the high price of HNO_3 .

Liquid chlorine. G. ORNSTEIN. *Met. Chem. Eng.* 14, 21 (1916). Processes for producing Cl_2 are described, together with the methods of storing and handling liquid Cl_2 . The history, advantages and uses of Cl_2 , especially bleaching and H_2O sterilization, where it has proved to be superior to other methods.

Recent progress in electrolysis of alkali chlorides in fused alkali compounds for preparation of metals. R. SACCHINI. *chim. applicata* 4, 346-58 (1915).—A review.

Electrolytic zinc at Bully Hill. C. A. HANSEN. *Met. Ind.* (1916).—The $Zn(OH)_2$ process was developed to a point where it is possible to produce 10-20 tons of Zn per day at Bully Hill. The process, not applicable to use in the Montana, Idaho and Utah district, with regeneration of acid, was adapted to successful commercial use so that a complete 200 ton per day electrochem. plant including overhead would cost about \$2,500,000 as compared with \$4,000,000 for an equiv. retort plant. Furthermore, Butte-Superior concentrates carry a power rate of \$25.00-\$30.00 per h. p. yr. A table of costs for the process in Oklahoma and electrochem. process at Butte, Mo. N. Y. cost of \$49.00 for the former and \$41.42 for the latter. Pb and Cu residues of \$7.20 against \$22.70 for the latter. Pb and Cu are shown.

Multiple series electrolytic copper refining. P. L. GUNN. *Met. Ind.* 9-10 (1916).—A comparison of the advantages and disadvantages of the multiple series electrolytic copper refining process.

The structure of copper deposits from technical processes. W. WIMPELMANN. *Z. anorg. allgem. Chem.* 93, 287-310 (1916). Deposits from various sources and of various thicknesses were examined under a microscope. The crystals always grow at right angles to the surface. If of curved surfaces or corners they intersect each other. Low c. d. gives a coarse structure which is, however, less regular in the latter. Increases with increased c. d. and at 0.15-0.2 amp./sq. cm. f. s. With a rotating tube cathode, very small crystals are formed. By the polishing device used in the process. High c. d. and electrolyte increased the hardness to abrasion of the cathode side. The greatest hardness was obtained in the finely cryst. sample.

Progress in electroplating. C. H. PROCTOR. *Metal. Ind.* (1916).—The processes for bronze or brass plating and electro-cleaning are carried out in solutions containing H_2O 4550 cc., soda ash 170 g., commercial $NaOH$ 17 g.

Al silicate 7.05 g., NaCN 28.35 g., and CuCN 28.35 g., worked at a temp. of 180°, voltage 4-6, amp. 25 per sq. ft. gives good results. The soln. is prepd. in an Fe tank. Anodes of respective metals are connected with the tank. The salts are added in the order named and partial replacement of CuCN by Zn(CN)₂ causes brass deposition. Metal deposits rapidly, but requires high amperage. W. H. BOYNTON.

Electroplating engineering (drying and driers). C. B. WILLMORE. *Metal. Ind.* 14, 8-10(1916).—The first of a series of articles deals with drying and driers (4 types illustrated). The spontaneous drying process consists of dipping the work into hot H₂O, swinging around and allowing to stand in the air. A steam table with hot box-wood or maple sawdust is better for work not simple in design. A rapid current of hot air on the work in a wire basket is effective except when the work contains pockets or surfaces not readily reached by the air blast. W. H. BOYNTON.

Removing iron scale by pickling; theory and practice. CARL HERING. *Met. Chem. Eng.* 13, 785-6(1916).—The advantage of the electrolytic process, in which the metal is made the cathode in dil. H₂SO₄, over simple dipping in the acid is pointed out, there being much less metal wasted. W. T. HALL.

Zinc-coating heating coils. ANON. *Elektrochem. Z.* 22, 203-4(1916).—A short discussion of the comparative value of the electrolytic and dipping processes. W. E. RUDER.

Selenium cells. W. R. COOPER. *Electrician* 76, 676-8(1916).—A general account of the properties of the different modifications of Se, the effects of light, etc. Also a review of the various theories advanced, details of cell construction, important applications, etc. C. G. F.

Potential differences at liquid contact surfaces. The effect of the size of the boundary between liquid surfaces upon the electromotive force. A. C. CUMMING AND E. GILCHRIST. *Elektrochem. Z.* 21, 290-4; 22, 9-13(1915).—Cell combinations of the type (a) Hg | HgCl | 0.1 N KCl | 5 N HCl | 0.1 N KCl | HgCl | Hg (b) in which the Hg contact surfaces *a* and *b* were dissimilar, were investigated. When one contact surface was compact and the other broken up, no appreciable p. d. between the 2 ends of the cell combination was observed. According to values calcd. from the equations of Henderson and of Planck, however, a p. d. should exist. The discrepancy may be due to insufficient difference in the sharpness of the contact surfaces, or to inaccuracies in the equations. When the 2 contact surfaces were fixed and defined in tubes of different diams., a p. d. was observed which usually increased with the time of contact. This effect was most pronounced when one surface was fixed in a capillary and the other in a tube of considerable width. The authors conclude that in order to obtain accurate measurements, it is necessary to produce a fresh contact surface shortly before making the measurement. Capillary tubes should be avoided, and it is advisable to mix the liquids mechanically at the contact surface shortly before measuring. Some measurements are given with cells of the type N KCl | N HCl or N NaOH | N KCl in which a membrane is interposed at one contact surface. Parchment, hardened filter paper, "cargil" membrane, gold-beaters' skin, collodion on silk and fine silk were tried. All except the latter gave appreciable p. ds., the e. m. f. changing sign when NaOH soln. was substituted for HCl. F. A. STRAUSS.

A new dry storage battery. ANON. *Elec. Rev. West. Elec.* 68, 169(1916).—A description of a Pb cell, about the size of a standard No. 6 dry cell, which may be recharged indefinitely. The outer case of turnplate steel is lined with acid-proof material, insuring great durability and rigidity, combined with light wt. The electrolyte is packed in around and between the cylindrical plates to form a compact, solid mass. A mineral condenser at the top of the cell checks escape of moisture by automatically condensing

and returning it to the battery. Cylindrical Pb plate construction allows tight packing and eliminates danger of short circuit or distortion. The battery has a capacity of 30 amp. hrs. at a discharge rate of 2.5 amp. for nearly 12 hrs. The charging rate is 3.5 amp. for about 8 hrs. It is immune to "sicknesses" to which the liquid Pb batteries are prone. No further details are given.

W. H. BOYNTON.

The reduction of lead sulfate. G. A. PERLEY AND C. W. DAVIS. *J. Phys. Chem.* 20, 151-63(1916); cf. *C. A.* 6, 714, 1259.—A study of the reduction of PbSO_4 in contact with Pb and NaOH soln. Pure Pb exposed to 3 *N* NaOH soln. in a closed vessel was found to dissolve very slowly even when warmed. Cold dil. NaOH soln. reacted with PbSO_4 to form yellowish green crystals, but no reduction to metallic Pb took place. Pb strips with grooves filled with PbSO_4 paste were immersed in 3 *N* NaOH soln. The PbSO_4 first turned yellowish green and then a black ppt. was formed, starting first where the PbSO_4 was in direct contact with the Pb. All the PbSO_4 was finally replaced by a deposit of finely divided Pb. During this reaction the Pb strip became corroded, and weighings showed that the process resulted in a net loss of Pb. To det. whether reduction was caused by the establishment of a concn. cell, a series of measurements was made with a salt bridge cell, varying the electrodes and the electrolyte. It was found that the rapid formation of fine Pb crystals is due to a concn. cell consisting in principle of $\text{Pb} | \text{NaOH} | \text{Na}_2\text{SO}_4, \text{PbSO}_4 | \text{Pb}$. The NaOH dissolves the PbSO_4 and the denser soln. thus formed flows to the bottom of the container while fresh soln. flows in from above to replace it, thus causing concn. changes. It seems necessary to assume that the conversion of Pb^{2+} ions into PbO_2^{--} ions takes time, and that the amt. of PbSO_4 dissolved as such is greater than it should be until equil. is reached. The formation of Pb crystals on the lower edge of the plate is due to another concn. cell: Pb dil. $\text{Na}_2\text{PbO}_2 | \text{concd. Na}_2\text{PbO}_2 | \text{Pb}$.

F. A. STRAUSS.

The regeneration of sulfated storage cells. G. A. PERLEY AND C. W. DAVIS. New Hampshire Coll. *J. Phys. Chem.* 20, 164-7(1916); cf. preceding abstract.—Badly sulfated storage battery grids were immersed in normal solns. of various Na salts and a charging current passed through at a c. d. of 6.5 amp. per sq. ft. Reduction of the sulfate deposit at the cathode was accomplished only by the use of solns. of NaOH, Na_2SO_4 , Na_2CO_3 , Na_2HPO_4 and Na_2SO_3 . Far better reduction occurred when 2 dummy positive grids were employed outside the negative plates in addition to the usual + plates. The rate of reduction was greatest and corrosion least with Na_2SO_3 soln. The use of NaOH caused deposition of much PbO , considerable corrosion and removal of the active material of the grids. Na_2CO_3 soln. caused the formation of difficultly reducible basic Pb salts at the cathode. Na_2HPO_4 soln. caused corrosion and the deposition of basic salts at the anode. The use of Na_2SO_3 soln. caused a hard cryst. metallic deposit at the cathode which produced buckling of the grids.

F. A. STRAUSS.

Standby battery for a. c. distribution service. J. LESTER. Woodbridge. *Elec. World* 67, 257-60(1916).—An illustrated paper describing the use of a storage battery in a substation to protect against interruptions in service. The app. was arranged so that in case of trouble the battery would take up the local a. c. load without interruption, but would not feed into the entire high tension distribution system through the 13,800-volt feeders and tie lines. An Exide battery of 344 cells, with a capacity of 2250 amp. for 1 hr., or 4650 amp. for 20 min. was connected to the railway bus bar between the terminals of the motor generator sets and the outgoing railway feeders, and a reverse current relay installed in the d. c. circuit between the battery and the motor generator sets. Trouble on the high tension circuits would reverse the current between the battery and the generators, and the relay would trip the 2 oil switches, opening up the connection between the high tension feeders and the local distribution circuits, leaving

the battery connected to the latter through the motor generator sets. In order to maintain a const. voltage during emergency discharge, the battery was provided with motor operated end-cell switches, automatically controlled by a contact voltmeter across the battery terminals.

SHERMAN EASTMAN.

Battery charging equipment. T. H. SCHORFF AND A. M. CANDY. *Elec. J.* 13, 28-36(1916).—A discussion of the general requirements and characteristics of battery charging equipment. Photographs and descriptions of a number of commercial installations are given.

F. A. STRAUSS.

The mercury-arc rectifier for charging electric vehicle batteries. Q. A. BRACKETT. *Elec. J.* 13, 37-40(1916).—A description of an outfit designed especially for this purpose.

F. A. STRAUSS.

Battery-room floors impervious to acid. ANON. *Elec. World* 67, 433(1916).—Description of the floors of the N. Y. Edison Co.'s battery room. These are laid on ordinary concrete floors reinforced by steel girders. Over this is a 1:2:4 mix of concrete with a cement mortar finish. The surface is then painted with "Hydrex" compound and covered with 3 layers of butt-jointed acid-proof felt, the strips being run with the flow line of the room. Joints are bonded with hot "Hydrex" compound. Additional layers of felt and this compound are used around the corners and under the drain box. On top of this is another layer of concrete, felt, etc., and the whole covered with $2\frac{1}{4} \times 4 \times 8$ in. vitrified brick, the spaces between which are filled with $\frac{1}{4}$ in. hot "Hydrex" compound. The floors are graded to a gutter which empties into a lime box. When passing over steel girders a layer of neat cement and sheet Pb (4 lb. per sq. ft.) is added.

W. E. RUDER.

Electrolysis on underground pipe systems. A. F. GANZ. *Gas World* 64, 54-6 (1916); cf. *C. A.* 10, 428.—Extracts from a lecture.

F. W. SMITHER.

Consumption of carbon in the electric arc. I. Variation with current and arc length. II. Influence upon the luminous radiation from the arc. W. G. DUFFIELD. *Proc. Roy. Soc. London (A)* 92, 122-43(1915).—When the arc is extremely short the loss from the cathode of one C atom is accompanied by a transfer between the poles of the equiv. of 4 electronic charges. The loss per coulomb for a given c. d. increases with increasing arc length until a nearly const. value is reached at about 8 mm. The anode loss per coulomb is gradual at first and increases more rapidly as the poles are further sepd.; the cathode slope is very steep at the outset and shows no point of inflection. The ratio between anode and cathode losses for 2, 4, and 6 amps. was 1.36, 1.40 and 1.64, resp. For short arcs the loss per coulomb was about 3×10^{-8} g., which is very close to the electrochem. equiv. of C, namely 3.11×10^{-8} if C is assumed to be quadrivalent. Even with 100-amp. arcs this equiv. was closely followed. There follows a discussion of the theory of arcs and the mechanism of emission.

E. B. MILLARD.

The electric arc in vapors and gases at reduced pressures. W. A. DARRAH. Ohio. *Trans. Am. Electrochem. Soc.* 29 (advance copy); *Met. Chem. Eng.* 13, 915-8 (1915).—The object of this research was to find an arc lamp in which the supply of the material for the arc did not come from the electrodes but from a surrounding gas or vapor: an arc lamp which would not require trimming or materially more attention than the present incandescent W or C lamp. After a number of trials an arc lamp was constructed having 2 W electrodes enclosed in a heat-resistant glass bulb (Corning, G. 702 P). Into this hermetically sealed bulb various volatile halogen compounds were in turn introduced and the characteristics of the arcs investigated. Among the compounds tried out were: CCl_4 , SnCl_4 , TiCl_4 , SbCl_3 , SiCl_4 , PCl_3 and AlCl_3 . Particularly good luminous effects were obtained with TiCl_4 and TiCl_3Br_2 . Efficiencies as good as 0.25 watt per candle were obtained. Fortunately, since the chloride and bromochloride

of Ti dissociated at a higher temp. than WCl_4 , these vapors will not attack the W electrodes while the arc is playing. Numerous curves and photos are shown. C. G. F.

The history of the arc lamp. F. CONRAD AND W. A. DARRAH. *Elec. J.* 13, 103-8, 140-4(1916).—In these instalments the authors consider the enclosed arcs, Ti arcs, Hg vapor and C flame arcs. Profusely illustrated. C. G. F.

The manufacture of drawn tungsten wire. ANON. *Electrician* 76, 633-4(1916); see C. A. 10, 18. C. G. F.

Recent developments in electric incandescent lamps in relation to illuminating engineering. J. T. MORRIS. E. London College. S. R. MULLARD AND F. W. WILLCOX. *Illuminating Engineer* 9, 6-26(1916).—A symposium on the advances of elec. lighting in recent years. Particular emphasis is put on the new W arc lamp. Many tables and cuts are shown. C. G. F.

Operation of low voltage apparatus from high voltage circuits. F. SCHRÖTER. *Elektrotechn. Z.* 51, 677-9(1915); *Elec. World* 67, 441(1916).—Further applications of the Geissler tube having a Na or K amalgam cathode and an Fe anode with an atm. of mixed Ne and He (cf. C. A. 9, 2035). When an a. c. of a few milliamps. passes, the tube has a drop of 190 v. The tube may be used to operate a relay or in connection with a storage battery. The "double-battery system" for signals, etc., is also described. Various connections are shown in diagram. W. E. RUDER.

Artificial insulating materials. ANON. *Electrician* 76, 627-9, 670-81(1916).—The ideal electrical insulating material must mould readily besides having the desired electrical properties. There are 4 classes: (1) Good insulators at ordinary temperatures but not at higher temp. (2) Insulators with high dielectric strength which will not soften up to a temp. of 80°. (3) Insulators that are fireproof. (4) Insulators that will withstand very high temperatures. Of all materials tested to date mica shows the highest dielec. const. Bakelite exceeds mica in mechanical strength. A detailed, illustrated account is given of the important compounds and products on the English market today. C. G. F.

Recent progress in electrical smoke precipitation. F. G. COTTRELL. *Eng. Mining J.* 101, 385-92(1916); cf. C. A. 9, 1272.—A bibliography is given with this illustrated historical review. E. J. C.

Electrochemical synthesis of phenylhydroxylamine. F. M. FREDERIKSEN. *Trans. Am. Electrochem. Soc.* 28, 345-50(1916); see C. A. 10, 331. SHERMAN EASTMAN.

Silver plate for glass and porcelain (J. P.) 19. The Schoop electric oven (KORDA) 1. Switch and transformer oils (DIGBY) 22. Ignition of explosive gas mixtures by electric sparks (MORGAN) 24.

Storage battery. B. FORD. U. S., 1,169,788, Feb. 1. Structural features.

Electrodes for accumulators. A. CONNELL and H. S. HORNE. *Brit.*, 20,671, Oct. 7, 1914. A grid, preferably cylindrical, has rectangular apertures formed by vertical bars having grooves at the sides, and horizontal bars having holes to retain the paste. Such a grid can be cast in one piece.

Depolarizer for batteries of the Leclanché type. C. ELLIS. U. S., 1,169,943, Feb. 1. A depolarizer is formed of non-colloidal MnO_2 cemented to particles of graphite by 10% of a binder of colloidal MnO_2 . The depolarizer is a firm mass not readily broken and is especially suitable for use in small flash-light batteries.

Galvanic cell. M. L. KAPLAN. U. S., 1,170,819, Feb. 8. Depolarizers for Leclanché batteries are formed of particles of graphite bonded together with slightly

porous MnO_2 produced by heating graphite with Mn nitrate to 170° . Cf. C. A. 10, 563.

Porous copper electrodes for primary or secondary batteries. F. S. B. DE MELLO. U. S., reissue 14,051, Jan. 25. Cf. original pat. 1,148,152, C. A. 9, 2488.

Dry battery. W. HOPPIE. U. S., 1,169,258, Jan. 25. Positive electrodes of dry cell batteries are coated with a mixt. of glucose and flour to prevent deterioration of the cell before being put into active use.

Burning carbon electrodes. F. NAGELSCHMITZ. U. S., 1,170,313, Feb. 1. Electrodes formed of coke or anthracite with a binder of tar are packed in raw electrode material and gradually heated with a final temp. sufficiently high to drive out gases and volatilize the volatilizable portion of the tar. The gases and volatile substances driven off are collected and burned to heat the furnace.

Arc-light electrode. G. EGLY. U. S., 1,169,942, Feb. 1. A mixt. formed of Ce peroxide 3, CaO 1 and CaF_2 1 part is used as illuminating ingredient of arc-light electrodes. La or Di peroxide and BaO or SrO also may be used.

Anticathode for Röntgen-ray tubes. M. GUNDELACH. U. S., 1,170,247, Feb. 1. Metallic U is used alone or with other metals to form anti-cathodes, which produce rays of unusually great penetrating power especially suited for the treatment of carcinomata.

Volatilizing metals from ores. O. C. RUDOLPH. U. S., 1,171,255, Feb. 8. Complex ores containing volatilizable metals such as Zn, Pb and Ag combined with S are fused electrically without reduction and at the same time part of the constituents are volatilized. Air is then blown through the fused charge to volatilize additional metal. The volatilized Zn is dissolved in SO_2 soln. and the Pb is pptd. and recovered by filter-pressing. The Zn is recovered electrolytically.

Tungsten filaments. R. H. HENDERSON. U. S., 1,169,819, Feb. 1. W filaments are drawn through dies or otherwise mechanically reduced to the desired size while highly heated.

Apparatus and method for electrically ozonizing air. W. T. HOOFNAGEL. U. S., 1,169,825, Feb. 1.

Gas reactions in electric furnaces. A. HELFENSTEIN. U. S., 1,169,817, Feb. 1. N is blown into a molten quartz bath in an elec. furnace and passes into a bed of granular C overlying the molten quartz, forming Si_3N_4 . CCl_4 is made by introducing C, S and Cl into an elec. heated mixt. of C and S vapor above a bath of molten inert silicate slag. HCN is made by introducing equal vols. of C_2H_2 and N through a vertical electrode into a bath of slag carrying an overlying layer of animal charcoal.

Treating gases in the electric furnace. K. GRUHN. Ger., 285,665, June 19, 1913. The furnace is designed for the treatment of gases which deposit C. A mechanism is provided for the rotation of the electrodes, and for longitudinal adjustment.

Electric printing process. W. SCHUNIG and F. WINKLER. Ger., 286,124, Jan. 20, 1914. The design is applied, elec. conductive, to the form, on an insulated base. Between the printing form and the counter cylinder or plate, together with the paper to be printed, a color sheet is run, and upon it is a substance which develops a color upon the passage of the current, and this colored product is transferred to the mordanted paper. The paper may be coated with $\text{Al}(\text{OH})_3$ or an Al salt, which combines with the dye substance formed by the elec. current, as a lake.

Electrolysis of alkali halides. J. F. WEBB and W. W. WILLIAMS. Brit., 20,714, Oct. 8, 1914. In app. for the production of bleaching-liquor from a soln. of NaCl

or MgCl_2 , an anode having a substantially vertical active surface is provided with non-conducting deflectors which transmit the Cl to the back of the anode and distribute it through the liquid so as to cause circulation thereof. The deflectors, which may be of glass, traverse inclined slots in the anode and project slightly from its face and to varying distances from its back. Similar deflectors may be fitted in the cathode but do not project backwards, so that the H is confined to a definite path. The electrodes may be built up from bars of compressed artificial graphite, the upper faces of which are recessed to form slots. In the case of the cathode, these recesses are alternately near the ends and middle of the bars to give larger contact areas between the bars. The electrode bars are clamped at their ends against slate, porcelain, or like separators by vertical conductor bars of C , graphite, or the like, provided with terminals. Each anode conductor bar rests against a vertical flange on an end plate, and each cathode conductor bar is forced inwards by a wedge supported by an inclined flange on the end plate. Above the anode is a vertical insulating partition clamped between the same parts as the anode. The electrode elements may be compressed vertically by screws working in lugs on the end plates and engaging porcelain or slate blocks on said insulating partition. A bottom plate and tie-bars at the top connect the 2 end plates, which may be of slate or porcelain. As the anode is liable to disintegrate, the anode gas deflectors are partly supported by grooves in the anode conductor bar. Behind the cathode, and held between the wedges and inclined flanges, is a partition perforated so as to allow equalization of temp. while confining the H . The cathode may be of Pb instead of being formed by graphite bars. An anode may be arranged on each side of the cathode, which then has deflectors inclined alternately in opposite directions, so that the gas repeatedly passes from each side to the other. Six sets of 3 electrodes may be placed tangentially and symmetrically around an axis. Cylindrical electrodes may also be used. A cooling coil may be provided.

Electrolytic production of alkalis and chlorine. HORSCH & Co. Ger., 286,011, Mar. 30, 1913. The app. comprizes a horizontal or practically horizontal Hg cathode. Chloride solns. are employed. Cf. C. A. 9, 1281.

Electric endosmosis. GES. FÜR ELEKTRO-OSMOSE. Brit., 21,189, Oct. 19, 1914. Diaphragms capable of use in the sepn. or purification of colloids have their potential altered as required, either before or during use, by adsorption of substances or removal of previously adsorbed substances. Electro-osmotic methods may be employed for effecting adsorption or removal. The positive potential of a leather diaphragm may be increased by adsorption of Cr_2O_3 . Organic dyestuffs of positive or negative character may be adsorbed by diaphragms of vegetable, animal or inorganic origin. A negative diaphragm of viscose may, e. g., be changed towards positive potential for methylene blue. Removal of silicic acid from a clay diaphragm by boiling with NaOH soln. renders the diaphragm indifferent instead of electro-negative. In the treatment of glue soln. by elec. endosmosis between diaphragms, of which the 1 near the cathode is of viscose, Al_2O_3 added to the soln. is adsorbed by the viscose with consequent change of potential towards electro-positive. Migration of electro-positive substances towards the cathode is thus hindered. During the process, the soln. becomes acid, the Al_2O_3 is dissolved, and basic substances then migrate towards the cathode. Cf. C. A. 9, 2840.

Carbides of tungsten or molybdenum. VOIGTLÄNDER & LOHMANN METALL-FABRIKATIONS-GES. M. B. H. Ger., 286,184, Apr. 14, 1914. Because of their hardness, 9.8 on Mohr's scale, the carbides of W and Mo are technically valuable. Heretofore the production of these carbides has been difficult and costly since the elec. energy required in the elec. arc to produce the necessary temp. was diverted to the graphite crucible, which is a better conductor than W . These carbides are now produced, in as

large quantities as desired, in C-tube resistance furnaces. The formation of the carbides is effected from acid anhydrides or oxides mixed with suitable quantities of pulverized C, in a C crucible in the C-tube resistance furnace whose connections with the source of current are also of C. In this manner several kg. of W or Mo carbide can be fused at one time, and a uniform product of the highest degree of hardness obtained.

5. PHOTOGRAPHY.

LOUIS DERR.

Intensification. W. T. P. CUNNINGHAM. *Phot. J.* 56, 2-8(1916).—The best method for scientific work is to bleach the negative in HgCl_2 , rinse in dil. HCl , wash thoroughly, and redevelop with ferrous oxalate; this method allows repetition of the process. For less exacting work, the Cr intensifier is simple and apparently permanent. The procedure advocated is to bleach in a bath of K_2CrO_7 10 parts, HCl 5 parts, water 480 parts; decreasing the acid concn. to 1 part in 5 parts of K_2CrO_7 and 480 parts water increases the intensification. As soon as bleaching is complete the plate is removed from the bath and washed until stain disappears, then redeveloped with amidol. The process may be repeated.

L. DERR.

Some deductions from Swarzschild's rule. F. F. RENWICK. *Phot. J.* 56, 11-3 (1916).—Papers containing free sol. Ag salts apparently darken according to the law that the product of light-intensity and time of exposure gives a measure of the photographic effect, irrespective of the ratio of the factors; but this does not hold for washed emulsions, for which the equation must be written $I^m t = \text{const.}$, the exponent m averaging about 1.16. For detg. development factor and inertia of plates, it is, therefore, necessary to adopt some standard exposure if different makers are to obtain comparable speed numbers for their plates. An exposure of 10 sec. is suggested.

L. DERR.

Color reproduction by the Lippmann process. REINHOLD ARON. Leipzig. *Z. wiss. Phot.* 15, 65-78, 97-125(1915).—From extended expts. on the plates used in the Lippmann color-photography process, especially in regard to intensity and color of image of various types of source, the following conclusions, among many others, are drawn: The spectral image of the exposure to a homogeneous color is frequently not simply a broadened spectral line but is crossed by dark interference bands which bear a relation to the number of elementary mirrors formed and to the loss of intensity of the light by passage through a single elementary mirror. The wave length of the reproduced color is affected by fixing and humidity. The intensity of the reproduction of a monochromatic radiation at first increases with increasing exposure time, then reaches a max., and finally decreases slowly but continuously. The relation is much more complicated when several colors are superposed.

PAUL D. FOOTE.

Color photography. W. BUCHANAN-TAYLOR, T. F. DAWE, F. WILLMOT and J. F. SHEPHERD. *Brit.*, 20,433, Oct. 1, 1914. In a process, applicable also for cinematography, 2 or 3 negatives are taken through color screens, and black and white positives are printed from them in the usual way. One of the positives, say the positive which is to be the blue positive, is treated with a soln. of $\text{K}_2\text{Cr}_2\text{O}_7$ so as to sensitize the gelatin in the emulsion layer. A print is made from a second positive, and the film dyed with the corresponding dye for the second color, and washed. If 3 negatives and positives are used, the film is again sensitized with $\text{K}_2\text{Cr}_2\text{O}_7$ soln., printed from the 3rd positive, dyed a 3rd corresponding color, and washed. The film may then be treated in a bath containing ferric NH_4 citrate and $\text{K}_3\text{Fe}(\text{CN})_6$ to tone the 1st positive picture blue.

diaminocobaltic hydrogen tartrate, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2[\text{CHOH}]_2\text{CO}_2\text{H}$; the corresponding *meso-tartrate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2[\text{CHOH}]_2\text{CO}_2\text{H}$; *glutaric acid-trans-dichlorodiethylenediaminecobaltic hydrogen glutarate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2[\text{CH}_2]_3\text{CO}_2\text{H} \cdot [\text{CH}_2]_2(\text{CO}_2\text{H})_2$; *thiodiacetic acid-trans-dibromodiethylenediaminecobaltic hydrogen thiodiacetate*, $[\text{Br}_2\text{Co en}_2]\text{CO}_2\text{CH}_2\text{SCH}_2\text{CO}_2\text{H} \cdot \text{S}(\text{CH}_2\text{CO}_2\text{H})_2$, (from the dibromo-bromide and thiodiacetic acid); *sulfonyldiacetic acid-trans-dichlorodiethylenediaminecobaltic hydrogen sulfonyldiacetate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CH}_2\text{SO}_2\text{CH}_2\text{CO}_2\text{H} \cdot \text{SO}_2(\text{CH}_2\text{CO}_2\text{H})_2 \cdot 2\text{H}_2\text{O}$; *thiodilactylic acid-trans-di-chlorodiethylenediaminecobaltic chloride*, $[\text{Cl}_2\text{Co en}_2]\text{Cl} \cdot \text{S}(\text{CHMeCO}_2\text{H})_2$; *trans-dichlorodiethylene-diaminecobaltic hydrogen adipate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2[\text{CH}_2]_4\text{CO}_2\text{H}$ (with the *cis*-dichloro-chloride, the normal *cis*-salt, $[\text{Cl}_2\text{Co en}_2][\text{CO}_2]_2[\text{CH}_2]_4$ was obtained); *trans-dichlorodiethylenediaminecobaltic hydrogen dihydriacetate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CH}_2\text{S}_2\text{CH}_2\text{CO}_2\text{H} \cdot \text{H}_2\text{O}$; *trans-dichlorodiethylenediaminecobaltic hydrogen dihydriacetylacate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CHMeS}_2\text{CHMeCO}_2\text{H} \cdot \text{H}_2\text{O}$; *maleic acid-trans-dichlorodiethylenediaminecobaltic hydrogen maleate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CH}:\text{CHCO}_2\text{H} \cdot \text{CO}_2\text{HCH}:\text{CHCO}_2\text{H}$; *trans-dichlorodiethylenediaminecobaltic hydrogen fumarate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CH}:\text{CHCO}_2\text{H}$; *trans-dichlorodiethylenediaminecobaltic hydrogen citraconate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CMe}:\text{CH} \cdot \text{CO}_2\text{H}$; *trans-dichlorodiethylenediaminecobaltic hydrogen mesaconate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CMe}:\text{CHCO}_2\text{H}$ and *trans-dichlorodiethylenediamine cobaltic hydrogen itaconate*, $[\text{Cl}_2\text{Co en}_2]\text{CO}_2\text{CH}_2\text{C}(:\text{CH}_2)\text{CO}_2\text{H}$. The compds. thus formed are rapidly deposited from soln. as microcryst. ppts. Those derived from the *trans*-chloro-chloride are all green and, as many different shades of green are obtained, it is impossible to distinguish them clearly by color. The aq. solns. of all these compds. are more stable than that of the dichloro-chloride from which they were prepd., but on keeping, they slowly change in color, probably with the formation of chloro-aquo-compds. Owing to this transformation, none of the compds. could be recrystd., but according to the analytical figures they were always pptd. in the pure condition.

L. T. FAIRHALL.

Ethylamino-chromic compounds. HJ. MANDAL. Upsala. *Ber.* 48, 2055-7 (1915).—Sublimed CrCl_3 was treated with anhydrous EtNH_2 at low temp. (snow-salt). The resulting red powder was extd. with alc. or water and the ext. allowed to evap. The red cryst. product was found to be *pentaethylamino-chloro-chromic chloride*, $[\text{Cl}(\text{C}_2\text{H}_5\text{NH}_2)_5\text{Cr}]\text{Cl}_3$. It is readily sol. in water, gives the usual reactions of purpleo-Cr compds. and ppts. with H_2PtCl_6 , HgCl_2 and $\text{K}_2\text{Cr}_2\text{O}_7$, resp. The picrate, dithionate, and phosphomolybdate are also little sol., $\text{K}_4\text{Fe}(\text{CN})_6$, $\text{K}_2\text{Fe}(\text{CN})_6$, H_2SiF_6 , $\text{Na}_4\text{P}_2\text{O}_7$ and $(\text{NH}_4)_2\text{C}_2\text{O}_4$ give no ppts. From the chloride the *bromide*, *iodide* and *hydrogen sulfate* were prepd. Ag_2O gives aquopentaethylamino salts analogous to the roseo-Cr salts. These give an insol. cryst. ferricyanide.

A. R. MIDDLETON.

Antimony pentachloride and iodine. O. RUFF. Danzig. *Ber.* 48, 2068-76 (1915); cf. C. A. 4, 875; MOLES, C. A. 9, 2342.—From analytical data and investigation of temp.-conc. curves, R. concludes that for SbCl_5 solns. with less than 1.5% I, the reaction $\text{SbCl}_5 + \text{I}_2 = \text{SbCl}_3 + 2\text{ICl}$ takes place. With increased amts. of I the reactions $2\text{SbCl}_5 + \text{I}_2 = \text{SbCl}_3 \cdot 2\text{ICl} + \text{SbCl}_3$ and $3\text{SbCl}_5 + 2\text{I}_2 = \text{SbCl}_3 \cdot 3\text{ICl} + 2\text{SbCl}_3 + \text{ICl}$ also take place. Some ICl_3 and SbI_3 are also formed. The existence of the compds. with ICl was well established. Both form blue-black prisms much like I but orange yellow in transmitted light. They are distinguishable from each other only when side by side. Both melt at $62-3^\circ$ and are rapidly decomposed by atm. moisture. Both dissolve easily and completely in water, CCl_4 and CHCl_3 , slightly in SbCl_3 and ICl .

A. R. M.

Action of ultraviolet rays on mercuric chloride solution and on some mercury salts. JEAN POUQUET. *Compt. rend.* 161, 348-51 (1915).—A soln. containing 1 g. HgCl_2 in 20 cc. water, enclosed in quartz, was exposed at 15 cm. to a Hg-arc lamp. HgCl formed at once. The unreduced HgCl_2 found after 10 min. was 0.831 g.; after

10 min., 0.494 g.; 30 min., 0.582 g.; 50 min., 0.552 g.; 70 min., 0.528 g.; 90 min., 0.524 g. Hg is precipitated in H_2O is slowly changed to $HgCl_2$ and Hg, the reaction becoming more rapid with time. Qual. observations are appended on 22 salts of Hg, dry and moist, under the rays. Most are darkened more or less; a few are unaltered.

A. R. M.

Decomposition of potassium cyanate by heat. A. PORTEVIN. *Compt. rend.* 161, 1014-10 (1915).—On heating to $700-900^\circ$ a certain amt. of KCN is produced. At 700° 20.94% KCN was formed in 2 hrs., 28.49% in 4 hrs. At 900° 53.08% and 48.91% were formed in 2 and 4 hrs. resp. A mixt. of KCNO with 50% KCN contained 60.06% KCN after 4 hrs. at 700° ; a mixt. with 75% KCN contained 82.40% KCN in one case and 82.62% in another after 4 hrs. at 900° ; a mixt. with 50% KCN after 4 hrs. at 900° contained 70.26% KCN; a mixt. with 25% KCN after 4 hrs. at 900° contained 59.81% KCN.

A. R. M.

Oxidation of sodium azide by iodine. F. RASCHIG. *Ber.* 48, 2088-92 (1915). cf. Sommers and Brown, *J. A.* 10, 578.—The action of I on NaN_3 when a small crystal of thiosulfate is added is not due to tetrathionic acid. R. here describes some expts. from which he concludes that the catalyzer is probably a substance like $NaIS_2O_3$ which readily gives up I to NaN_3 , the residue NaS_2O_3 again taking up I from soln. If 10 cc. of 0.1 N NaN_3 soln. is quickly added to 20 cc. 0.1 N I soln., and 1 cc. portions are added to 10 cc. NaN_3 soln. at 10 sec. intervals, the first causes vigorous evolution of N_2 gas, which is soon up; the action is less vigorous in each succeeding portion and ceases after 10 min. If 10 cc. each of thiosulfate and I are mixed, allowed to stand a few min. and then 10 cc. more I are added, the mixt. has no action on NaN_3 . Free NaI does not prevent the oxidation; formation of H_2SO_4 by a side reaction destroys NaN_3 . NaN_3 solns. are likewise unaffected by Br in presence of Na acetate. No other N compds. which are unoxidized by NaI . Sulfonic acids, urea, etc., are similarly oxidized upon adding thio-
The addition of a crystal of $Na_2S_2O_3 \cdot 5H_2O$ acts similarly to thiosulfate on NaN_3 .
The formation of $NaIS$. $SnCl_2$, $FeSO_4$ and $HAsO_3$, which can take up NaN_3 as catalyzers toward NaN_3 , nor do acid or neutral sulfitcs.

A. R. M.

Deposition of manganese solutions in presence of the air. VICTOR LENHER. *J. Soc. Chem.* 38, 638-40 (1916).—Solns. contg. 1% $MnCl_2$ were sealed up in tubes of glass spar and a piece of metal, mineral or metallic compd., and the deposition of MnO_2 formed by neutralization and oxidation was observed for a certain time. Pb and Bi accelerate the deposition of MnO_2 , more forming in a shorter time than was formed in several weeks in a tube in which only $MnCl_2$ and $CaCO_3$ were present. Hg, Cu, Zn, Ni, Co, Cd, Ag, Au, HgS , millerite, pyrite, chalcoppyrite and blende were without effect, even after several months. The same acceleration was observed with Pb compds. as with the metal itself; salts of Mn, Sb, and Sn retarded the action, probably on account of their reducing action on MnO_2 . The presence of arsenates, Sb_2O_3 or SnO_2 allows the deposition of MnO_2 as well as if no "catalyzer" at all were present. The acceleration of pptn. of MnO_2 by Pb compds. may account for the presence of MnO_2 in nature, though no Pb is known to be associated with the MnO_2 deposits.

E. B. MILLARD.

Ternary system calcium oxide, aluminium oxide, magnesium oxide. G. A. RANKIN AND H. E. MERWIN. *J. Am. Chem. Soc.* 38, 568-88 (1916); cf. C. A. 3, 2925; 4, 702.—The system is a simple one in which there is no ternary compd. stable in contact with the melt, so that the equil. is between the components and the compds. $3CaO \cdot Al_2O_3$, $3CaO \cdot 3Al_2O_3$, $CaO \cdot Al_2O_3$, $3CaO \cdot 5Al_2O_3$ and $MgO \cdot Al_2O_3$ in ternary solns. The relations found to subsist between the components and the compds. in binary and

ternary systems are shown in concn.-temp. diagrams for CaO-MgO , $\text{MgO-Al}_2\text{O}_3$, spinel- Al_2O_3 , together with a space model of the system. Optical and crystallographic properties of these compds. have been given in previous papers, but a few additional notes are made on $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ and $\text{CaO} \cdot \text{Al}_2\text{O}_3$. A new form of Al_2O_3 ($\beta\text{-Al}_2\text{O}_3$) was discovered whose relations to corundum ($\alpha\text{-Al}_2\text{O}_3$), the only other form previously known, could not be definitely established, although it appears that $\beta\text{-Al}_2\text{O}_3$ is monotropic with respect to $\alpha\text{-Al}_2\text{O}_3$. The relations of each of these forms, in the binary system $\text{MgO-Al}_2\text{O}_3$, involved solid soln., the extent of which was detd. E. B. MILLARD.

Oxidation of hydrogen sulfide by ozone in water vapor at 120° . U. BRESCIANI. Pisa. *Ann. chim. applicata* 4, 343-6(1915).—Steam from an Fe boiler was passed through a long tube heated by gas flames, so that its temp. was about 120° , and then into an asbestos-covered Sn worm about 2 m. long. At the inlet to the worm, H_2S and O_3 were admitted by side tubulures, and the vapors issuing from the worm were led into another Sn worm and there condensed. The H_2S had a concn. of about 0.02% in the gaseous mixt., 100 cc. of it being used in a given time together with 1110 cc. of ozonized O (from the decompn. of NH_4 persulfate by HNO_3). The condensed liquid was immediately treated with CdCl_2 , the pptd. CdS sepd., and the liquid concd. to small vol. The excess of CdCl_2 was eliminated by KOH , the filtrate rendered acid with HCl , and BaCl_2 added to ppt. the H_2SO_4 present from the oxidation. In this way it was found that only about 5% of the H_2S used was transformed. S. LEVY.

Further note on black phosphorus. P. W. BRIDGMAN. *J. Am. Chem. Soc.* 38, 609-12(1916); cf. *C. A.* 8, 3160.—There are 2 varieties of "red" P, a bright brick-red variety formed by heating white P to red heat at a pressure of 500 kg. in an atm. of N, and a violet P (probably the same as that of Smits) made by heating white P under pressure in the presence of Na as a catalyzer. White P with a trace of Na was put under 4000 kg. pressure at room temp., and the temp. raised to 200° at const. vol. The rise of pressure during this heating was only 500 kg. The pressure was increased to 13000 kg. for 45 min., but the transition to black P did not occur. On cooling and releasing the pressure the white P was entirely changed to violet P, and a piece of bright red P which had been placed originally at the bottom of the mass was unchanged. The change from white to violet took place during the heating at a temp. below 200° . The d. of violet P is 2.348. A piece of violet P and a piece of red in the presence of I were both placed in the pressure app., and 8000 kg. applied at 20° , then warmed to 200° at const. vol. and the pressure increased to 12500 kg. for 5.5 hours. On cooling and releasing the pressure no black P was found. There was no change whatever in the violet P, but the red piece had changed to the same violet as the other. The violet form is the stable one between 8000 and 12000 kg. at 200° . An attempt to change red P to black by surrounding it with white P and changing the latter to black in the usual way was without result; the red was found unaltered in the midst of a mass of black. E. B. MILLARD.

The preparation of phosphorescent calcium sulfide. P. BRETEAU. *Compt. rend.* 161, 732-3(1915).—According to B., it is not necessary to add Na_2CO_3 and NaCl to the fusion mixt. in prepg. phosphorescent CaS . 100 g. of freshly pptd. CaCO_3 , free from alkali metal carbonate or chloride, are heated with 30 g. of pulverized S in a muffle furnace at red heat for 1 hr. After cooling, the mass is impregnated with $1/10000$ of its wt. of Bi (using an EtOH soln. of the basic nitrate). The resulting product exhibits marked phosphorescence. Mo, W or V may be substituted for Bi. Also in *J. pharm. chim.* 13, 33-7(1916). L. T. F.

Reduction of lead sulfate (PERLEY) 4. The various modifications of carborundum (BAUMHAUER) 8.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

The preparation of decinormal solutions. C. M. VAN DER FREN. *Chem. Weekblad* 12, 1021-2 (1915).—When $(\text{CO}_2\text{H})_2$ is used for normal acid solns. it should be crystd. from HCl and then repeatedly recrystd. from H_2O . Acids, bases and AgNO_3 can be standardized by means of NaCl, which is easily obtained chemically pure, and solns. of which are reliable and unchangeable. Commercial AgNO_3 does not suffice for the prepn. of 0.1 N AgNO_3 soln. even when previously melted. The best way is to standardize a AgNO_3 soln. against pure NaCl, as recommended by Fresenius. 0.1 N HCl is standardized after neutralization with CaCO_3 by means of 0.1 N AgNO_3 soln. and can be used for the standardization of 0.1 N base. J. T. FLOHIL.

The determination of the acid or alkali content of solutions of organic colors. J. F. SACHER. *Farben-Ztg.* 21, 323 (1916).—Titration of solns. of org. colors is practically impossible, since the color of the indicator is masked. A neutral aq. soap soln. can be used as indicator, since the addition of acid causes a turbidity due to the liberation of fatty acids. Unsaponifiable oils must be absent, but the presence of a small amt. of glycerol does not interfere. A convenient indicator is prepd. as follows: 1 g. of shellac is dissolved in 100 cc. of 96% EtOH, a small amt. of KOH is added, and the soln. filtered. The perfectly clear filtrate is made exactly neutral, and 1 cc. of this soln. is added to 100 cc. of the color to be tested, which is then titrated with standard acid or alk. E. W. BOUGHTON.

A new method for the volumetric determination of thiosulfate in the presence of sulfide, and remarks on the determination of thiosulfate in the presence of sulfite, bisulfite and sulfide. A. SANDER. Darmstadt. *Chem. Ztg.* 39, 945-7 (1915).—*Thiosulfate and sulfide*: The method, which is rapid and accurate, is based on the reactions: $3\text{HgCl}_2 + 2\text{Na}_2\text{S} = 4\text{NaCl} + \text{HgCl}_2 \cdot 2\text{HgS}$, and $2\text{Na}_2\text{S}_2\text{O}_3 + 3\text{HgCl}_2 + 2\text{H}_2\text{O} = 2\text{Na}_2\text{SO}_4 + 4\text{HCl} + \text{HgCl}_2 \cdot 2\text{HgS}$. First, titrate a measured vol. of the soln. with 0.1 N I. To an equal vol. add an excess of HgCl_2 and swirl a few sec. till the ppt. turns pure white; then add NH_4Cl and titrate the turbid soln. with 0.1 N NaOH and Me orange. Half the NaOH soln. required = the cc. 0.1 N I for the thiosulfate; the difference between this and the cc. I in the 1st titration = cc. 0.1 N I for the sulfide. *Thiosulfate and sulfite*: The method of Bosshard and Grob (*Z. physik. Chem.* 9, 192 (1892)) is used. Titrate a measured vol. with 0.1 N HCl till the sulfite is changed to bisulfite, then add an excess of HgCl_2 and titrate with 0.1 N NaOH, as above. The difference in these titrations is the acid equiv. to the thiosulfate. Or, titrate with 0.1 N I, then to another portion add an excess of HgCl_2 and titrate the acid formed from the thiosulfate. *Bisulfite and sulfite*: Titrate a vol. with 0.1 N I. To an equal vol. add excess HgCl_2 and titrate with 0.1 N NaOH. Twice the cc. NaOH = the cc. 0.1 N I required for the bisulfite. *Thiosulfate, sulfide and sulfite*: These may be accurately detd. in less than 10 min. Allow 10 or 20 cc. of the soln. to flow into a measured vol. of 0.1 N I to which has previously been added, say, 10 cc. 0.1 N HCl. Titrate excess of I with $\text{Na}_2\text{S}_2\text{O}_3$, the difference (A) being the I equiv. to all. Add 2 drops Me orange and titrate with 0.1 N NaOH. The result less the 10 cc. HCl added at first is the cc. I (B) equiv. to the sulfite. To an equal vol. of the sample add excess HgCl_2 , swirl till the ppt. turns white, add NH_4Cl and titrate with 0.1 N NaOH and Me orange (C). Therefore, the cc. 0.1 N I required for the 3 substances are: thiosulfate, $C/2$; sulfite, B; sulfide, $A - (B + C/2)$. Other methods are discussed, comparative results tabulated, and a short bibliography appended. Cf. C. A. 1, 2069; 7, 3584; 8, 1071, 2132; 9, 279, 2042, 2357, 3114. J. H. MOORE.

Analysis of a mixture of alkali sulfides, thiosulfates, and dithionates. J. A. MULLER. *Bull. soc. chim.* 19, 8-9(1916).—Det. S present as sulfate by making the very dil. soln. slightly acid with AcOH and adding BaCl₂, keeping the soln. in an atm. of CO₂; finally weigh as BaSO₄. To det. sulfides and thiosulfates, obtain the titer with I soln. of an aliquot after dilg. with H₂O and acidifying with AcOH; place another aliquot in a small flask, acidify with AcOH, evacuate with H₂O pump for 10 min. with continual shaking to remove H₂S and titrate with I soln. to obtain thiosulfates; thionates do not interfere as the action of I in the cold for such short periods is negligible (*C. A.* 4, 722). **Thionates:** Acidify an aliquot with AcOH and remove H₂S as above, make strongly alk. with KOH, transfer to a Ag crucible, add a little KNO₃, evap. to dryness, cover and heat to dull redness. Take up with H₂O, acidify and det. as BaSO₄ in the usual manner; subtract BaSO₄ corresponding to sulfates and thiosulfates and calc. remainder to dithionate, as alkali sulfide present would reduce thionate compds. (tri- and tetra-) to dithionates. If S seps. during expulsion of H₂S (as with disulfides and polysulfides), it coagulates when the last of the dissolved H₂S is removed, and is filtered off on a small filter, dissolved in KOH + KNO₃, detd. as above, and used in calcg. the compn. of the mixt. An analysis reported of a known mixt. of Na₂S, Na₂S₂, Na₂S₂O₃ and Na₂S₂O₄ shows excellent results. F. W. SMITHER.

Decomposition of tetrathionates in alkaline solution as a source of error in certain iodine titrations. R. M. CHAPIN. *J. Am. Chem. Soc.* 38, 625-6(1916).—Tetrathionates are affected by the presence of NaOH, but not by NaHCO₃, especially in the presence of CO₂. No distinctly alk. substance should be added to an acid soln. before titration. A dil. soln. of Na₂SO₃ is recommended as a substitute for Na₂S₂O₃ (unreliable) as a discharge agent for I under the conditions prevailing in the detn. of As. E. B. MILLARD.

Oxalic acid titratable with methyl orange and iodide-iodate. G. BRUHNS. *Z. anal. Chem.* 55, 23-51(1916).—An exptl. study reported in detail from which B. concludes: (1) Pure crystd. (CO₂H)₂ is an excellent standardizing agent for volumetric analysis; it may be easily tested for impurities and can be kept for years in glass-stoppered bottles without undergoing any decompn. (2) (CO₂H)₂ may be detd. in the presence of alkalies and methyl orange with a sharp end point after the addition of at least an equal amt. of CaCl₂; the results do not vary from the calcd. sufficiently to affect ordinary investigations. The CaCl₂ should not be added until approx. all of the (CO₂H)₂ has been neutralized with alkali; otherwise the CaC₂O₄ carries down significant amts. of the acid. (3) There is a distinct tendency of (CO₂H)₂, even in very dil. solns., to form acid salts with the alkali earths (cf. *Z. anal. Chem.* 45, 575(1906); *Centr. Zuckerind.* 15, (1906); Gröger, *Z. angew. Chem.* 1890, 356). F. W. SMITHER.

The determination of bromine and iodine in the presence of chlorides. L. W. WINKLER. *Z. angew. Chem.* 28, I, 477-80(1915).—To det. Br in the presence of small amts. of Cl only (20 mg. in 100 cc. soln.), add to a 100 cc. soln. of the salt in a 200 cc. flask, a little powdered pumice stone and 25 cc. of a 50% H₂SO₄ soln. Heat to boiling and titrate with 0.05-0.1 N KMnO₄ soln. to a permanent pink. With Cl amounting to 100 mg. in 100 cc. add to 100 cc. of the sample contained in a distg. flask, pumice and acid as before but after each addition of KMnO₄ soln. distil off 2-3 cc. and note the color of the distillate. Absence of a brown tinge indicates the end point. Increase the density of the KMnO₄ soln. used by the addition of 250 g. Na₂SO₄·10H₂O per l. in order to facilitate its mixing with the Br soln. Sulfates and nitrates do not interfere but reducing agents must be absent. Should iodides be present, I will first distil off and condense in the tube leaving the distillate colorless. The appearance of a brown color indicates the end of the I oxidation but if there is doubt shake the distillate with CCl₄. In the case of sea water or mineral waters containing large amts. of Cl add KMnO₄

soln. and distil over the Br into dil. H_2SO_4 ; boil off the excess of SO_2 and det. Br as before. Reduce high iodide contents by adding to 100 cc. of the soln. 5 cc. H_2SO_4 and 5 cc. $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ (50 g. per l.) and distg. off 5 cc. Br in the distillate may be detd. iodometrically.

H. L. OLIN.

The chlorate and persulfate methods for determining manganese. H. KINDER. *Stahl u. Eisen* 35, 918-24, 947-53(1915).—Hampe's chlorate method was carefully tested in 8 different labs. with solns. containing known amts. of Mn and with crucible steel, "spiegel" and basic Bessemer steel. With small quantities of Mn excellent results were obtained but with high Mn a correction was necessary for Mn that went into the filtrate on washing the MnO_2 ppt. Such losses, however, were less with dil. K_2SO_4 or KNO_3 soln. (1.5:1000) than by washing with water. Oxalic acid soln. was found a little better than ferrous ammonium sulfate soln. for dissolving the MnO_2 . The results were, as a rule, a little lower than those obtained by the Volhard-Wolff method, the difference being due in part to the fact that the excess KMnO_4 used in the final titration causes high results in the latter method and low results in the former. The influence of Cu, Cr, Ni, Co, Ti, V, W, Mo, As, Pb and Sn was studied. In the case of Cr-steels the method was found unsuitable and ppts. of H_2TiO_3 , H_2SnO_3 or WO_3 cause trouble either by carrying down Mn or by running through the filter and making the final end point uncertain. In the analysis of cast Fe, the results are somewhat low if the graphite is not filtered off, but the effect of the graphite is not so great as in the Volhard method. The chief advantages of the chlorate process over the Volhard method are that larger samples may be used and the titration may be carried out in the flask originally used. The following directions are recommended: Dissolve 1 to 3 g. of Fe or steel in 60 cc. HNO_3 (d. 1.2). After the disappearance of brown fumes add 6 to 8 g. KClO_3 , in tablets or large crystals, and evap. the soln. to about 20 cc. Cool somewhat and filter, without dilg., through asbestos. Wash first with cold water and then with hot water. Transfer the filter and ppt. back to the original flask, add 10 to 20 cc. $\text{H}_2\text{C}_2\text{O}_4$ soln. (25 g. $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ dissolved in 1000 cc. water and poured into a mixt. of 400 cc. concd. H_2SO_4 + 1600 cc. water) 10 cc. H_2SO_4 (1:3) and dil. with hot water. When all the MnO_2 has dissolved, titrate the excess of reducing agent with KMnO_4 . In studying the persulfate method, the effect of temp. as well as of varying amts. of persulfate, AgNO_3 , HNO_3 and H_2SO_4 was detd. The results showed that varying results were obtained if the proper conditions were not maintained but that under favorable conditions the method is accurate and much more rapid than either the chlorate or Volhard methods. Cu, Ni, Ti, V, Mo and W have no influence upon the results but the presence of Cr or Co causes trouble with the end point. Cr-steel is not completely sol. in HNO_3 and is unsuitable for this reason also. As a result of many expts. the following procedure is recommended: Dissolve 0.2 g. of filings in 15 cc. HNO_3 (d. 1.2) and heat until all nitrous fumes are expelled. Add 50 cc. 0.1 N AgNO_3 soln. and 2 cc. persulfate soln. (500 g. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ per l.), or more if above 1% Mn is present, and heat to 60°. After maintaining this temp. 5 min., cool, dil. to about 125 cc., add 3 cc. NaCl soln. (12 g. per l.) and titrate promptly with Na_2AsO_3 soln. (5 g. As_2O_3 and 15 g. Na_2CO_3 dissolved in hot water and dild. to 10 l.).

DONALD BELCHER.

The determination of cobalt and nickel in cobalt metal. C. A. KNITTEL. *Metal Ind.* 14, 77-8(1916).—Treat 1 g. of drillings in a 150 cc. conical flask provided with a trap (made of a CaCl_2 tube) with 20 cc. of HCl (d. 1.12), heating gently until all action ceases; add 1 cc. concd. HNO_3 and heat till action ceases, rinse and remove trap and evap. soln. to a sirup. Add 30 cc. of H_2O , filter, wash with H_2O (+ a few drops of HCl); ignite the residue and fuse with 5 times its wt. of $\text{K}_4\text{S}_2\text{O}_7$, dissolve, melt in a little H_2O and add to main filtrate. Warm the slightly acid soln. and saturate with H_2S , filter off sulfides of As, Cu, etc., wash with acidulated H_2S water (1 cc. HCl :100 cc. H_2O),

receiving filtrate and washings in a 350 cc. casserole; evap. down to a few cc., oxidize Fe^{2+} with a few drops of $\text{Br} + \text{H}_2\text{O}$, add 0.2 g. of NH_4Cl , and evap. to dryness at H_2O -bath temp. Take up with a little H_2O , add 0.1 g. HCOONH_4 , dil. to 50 cc., heat until a ppt. of basic Fe formate seps., add very dil. NH_4OH until the soln. is only slightly acid; heat for a min. or so, let settle, filter, and wash with a hot 0.1% HCOONH_4 soln. Dissolve ppt. off the filter with hot HCl (1:5), receiving filtrate in the casserole in which the pptn. was made, neutralize with NH_4OH , add HCOONH_4 and proceed as above. To the united filtrates from the 2 Fe sepsns. add 8 cc. concd. H_2SO_4 , and evap. to copious SO_3 fumes; take up with H_2O , transferring to a 180 cc. tall beaker and keeping the vol. within about 50 cc.; add gradually 60 cc. of concd. NH_4OH (keeping soln. cool), then 10 cc. of 20% $(\text{NH}_4)\text{HSO}_4$ soln., electrolyze with a current of 2.5 amp. till soln. is colorless, rinse down cover glass and side of beaker with H_2O , reduce current to 0.5 amp. and electrolyze till a few cc. of the electrolyte show no Co or Ni with K_2CS_2 . Remove and dry cathode with usual precautions; weigh Co + Ni; dissolve deposit with 30 cc. of HNO_3 (1:3), rinse and remove cathode, boil to expel nitrous fumes; dil. to 500 cc., neutralize with NH_4OH , make faintly acid with HNO_3 , heat to $50\text{--}60^\circ$, add 30 cc. of a 1% alc. soln. of dimethylglyoxime, followed by 10 cc. of 20% AcONH_4 soln. Let stand 4 hrs., filter on a gooch, wash twice with hot H_2O , redissolve, and repeat the pptn. in a vol. of 200 cc.; let stand 1 hr. in a warm place, filter on a gooch, wash with hot H_2O , dry at $130\text{--}140^\circ$ for 45 min., cool, and weigh. $\text{Wt. of ppt.} \times 0.20316 = \text{Ni}$. Obtain Co by difference from Ni + Co found by electrolysis. Co metal as now commonly found in the market contains 98–98.5% Co (+ Ni). K. used cathodes of the perforated type with an effective surface of 90 sq. cm., spiral anodes made of 0.04 in. wire, $\frac{5}{8}$ in. diam., $6\frac{1}{2}$ turns. Notes and precautions are given. F. W. SMITHER.

Separation of gold and platinum from other metals. A. C. CHRISTENSEN. *Archiv. Pharm. Chem.* 22, 105–6(1915).—A slightly acid soln. is treated with hydrazine sulfate on the water bath and allowed to stand for 1 hr. The ppt. after digestion with HNO_3 contains the Au and Pt. The sepn. is quant. A. R. ROSE.

The qualitative analysis of the iron group in the presence of phosphates. R. GILMOUR. *Chem. News* 113, 1–3, 13–5(1916).—Inaccuracies in existing methods are discussed. When PO_4 is present with the alk. earths, the basic acetate sepn. is unsatisfactory; a better method is to ppt. the alk. earths as sulfates before sepgg. the Fe group. Expts. showed that a considerable excess of Na_2O_2 is required in the peroxide sepn. of Al, Cr and Zn. Unless a very large excess of NH_4Cl is present, Mg is pptd. with Al by NH_4OH . The phosphate sepn. as usually carried out with $(\text{NH}_4)_2\text{HPO}_4$, AcOH , AcONa and FeCl_3 , is inaccurate in the presence of Ba, and to a less degree in the presence of Sr or Ca, since appreciable amts. of these metals remain with the FePO_4 ppt. FePO_4 is probably hydrolyzed on boiling and BaHPO_4 , which is insol. in AcOH , is formed. Expts. showed that, in general, 4–5 cc. of 2 N AcONa and 1 cc. of 4 N AcOH in a vol. of 60–70 cc. will ensure complete removal of Fe up to at least 140 mg. The basic acetate sepn. of Fe and PO_4 from Co and Mn was found to be quite satisfactory under the conditions given above. The pptn. of Co and Ni by means of H_2S in a hot soln. containing 1 cc. of 4 N AcOH and 6 cc. of 2 N AcONa is complete. A complete scheme for the examn. of a soln. for metallic radicals is given, of which the following is an outline. Remove Pb, Ag and Hg^{2+} with HCl in the usual manner. Remove and sep. the metals of the Cu and Sn groups by G.'s method (cf. C. A. 9, 1725). Boil the soln. to remove H_2S . Remove the alk. earth metals by means of H_2SO_4 and EtOH . The pptd. sulfates are converted into carbonates and analyzed by G.'s method (C. A. 9, 1725). Heat the filtrate on the water bath for some time to remove EtOH , add NaOH and then a considerable quantity of Na_2O_2 . Boil for some mins. and filter. The filtrate contains Al, Cr and Zn and most of the PO_4 if the latter is present. The ppt.

contains $\text{Fe}(\text{OH})_2$, $\text{Ni}(\text{OH})_2$, $\text{Ni}(\text{OH})_2$, $\text{MnO}(\text{OH})_2$, $\text{Co}(\text{OH})_2$, $\text{Mg}(\text{OH})_2$, and phosphates of these metals. The filtrate is examd. as usual for Al, Cr and Zn. The ppt. is dissolved in HCl and the soln. evapd. to dryness. The residue is taken up in H_2O , tested for Fe, and the Fe and PO_4 removed by the basic acetate process as follows: Add Na_2CO_3 soln. until a slight permanent ppt. forms; remove this by adding dil. HCl drop by drop, then add 1 cc. of 4 N AcOH and 6 cc. of 2 N AcONa, followed by FeCl_3 until the mixt. assumes a pale yellow color. Boil for 1 min. and filter hot. The filtrate contains Ni, Co, Mn and Mg. Heat to boiling and pass in H_2S , pptg. Ni and Co as sulfides. Identify Co as K cobaltinitrite and Ni as $\text{Ni}(\text{OH})_2$ after sepg. from Co by means of KCN and bromine H_2O . Make the filtrate from the NiS and CoS alk. and pass in H_2S , pptg. MnS. Mg is identified in the filtrate by pptn. as MgNH_4PO_4 . Na and K are tested for in a portion of the original soln., after removing all other metals by means of NH_4OH , NH_4Cl , H_2S and $(\text{NH}_4)_2\text{CO}_3$. If Mg is present make a sepn. with EtOH and $(\text{NH}_4)_2\text{CO}_3$. Test for Na and K, after removal of NH_4 salts by ignition, in the usual way, viz., by flame tests and formation of K cobaltinitrite. The method of Mathers and Lee (cf. C. A. 9, 1730) with fluoboric and fluosilicic acids may be used. Directions are given in minute detail. Trials of the scheme with unknowns showed it to be quite satisfactory.

E. W. BOUGHTON.

Use of hydrofluoric acid in the separation of some heavy metals from tin, antimony, tungsten and molybdenum, by means of the electric current. L. W. MCCAY AND N. H. FURMAN. *J. Am. Chem. Soc.* 38, 640-52(1916); cf. C. A. 9, 277.—Standard solns. of most of the metals were prepd. and mixed as required. The paper is a report of the details of sepn. of each of the metals from the others by electrolysis.

E. B. MILLARD.

Crum's and Marshall's tests for manganese. L. DOBBIN. *J. Soc. Chem. Ind.* 35, 80-1(1916).—This article discusses the origin of the persulfate test for Mn. Minute quantities of Mn in soln. can be detected by warming with persulfate in presence of H_2SO_4 or HNO_3 with the addition of a drop of dil. soln. of AgNO_3 . This and the possibility of a quant. application was stated by Marshall in 1901 (*Chem. News* 82, 76). Many writers have mentioned Walters as the author of this, although his work was only a development of Marshall's publication.

H. M. LANCASTER.

Rapid method of separation of copper from other metals. A. APPELBANEY. *Chem. Analyst* 15, 18(1915).—The method is applicable to sepn. of Cu from Al, Co, Ni, Cr, Fe and Zn. Dissolve 1 g. of alloy sample in 10 cc. HCl and 2 cc. HNO_3 , and remove excess of acid by evapn. Dissolve the mixed chlorides in 50 cc. water, adding 4 g. $\text{KHC}_4\text{H}_4\text{O}_6$ to assist soln. and add a soln. of KOH. Cool, add a soln. of pure glucose and boil for 1 to 2 min. The sepn. of Cu as Cu_2O should be complete. The ppt. seps. rapidly in granular form but if the glucose is added to a warm soln. the ppt. is flaky and hard to wash. The Cu_2O may be dissolved in HNO_3 and estd. by the electrolytic or iodide method. Solns. of Bi on similar treatment ppt. metallic Bi, which can be easily filtered and washed.

H. M. LANCASTER.

The analysis of graphite. E. DONATH AND A. LONG. *Stahl u. Eisen* 35, 870-3 (1915); cf. C. A. 9, 1158.—The following reactions for anthracite are given: (1) on heating, very small amts. of volatile matter escape; (2) on boiling with concd. HNO_3 a brownish red soln. is obtained which gives $\text{Fe}(\text{OH})_3$ on addition of NH_4OH and a brown ppt. on addition of CaCl_2 and $\text{Pb}(\text{OAc})_2$; (3) KMnO_4 is reduced in boiling soln. with the formation of $\text{H}_2\text{C}_2\text{O}_4$ in appreciable amts.; (4) Na_2SO_4 , heated with the material to sintering, gives a mass whose soln. ppts. PbS with $\text{Pb}(\text{OAc})_2$. Only when all these reactions are encountered, especially (2) can one conclude the presence of anthracite. In reaction (3) HCOONa is used to reduce the excess KMnO_4 because the use of NaHSO_4

often misleads the analyst by the subsequent pptn. of CaSO_4 . 1% of anthracite may be detected. Several tables of complete analyses are given. Artificial graphites are generally free from S. Natural graphites decolorize blue and red litmus soln.; artificial do not. Natural graphites turn *p*-phenylenediamine soln. brown; artificial graphites behave indifferently. D. B.

Zinc-dust precipitation tests (discussion of paper of Nathaniel Herz). GILBERT RIGG. *Bull. Am. Inst. Mining Eng.* 1916, 513-4; *Mining Eng. World* 44, 122(1916); cf. *C. A.* 9, 2631.—A criticism of statements concerning the solubilities of Pb and Cd in Zn. A bibliography of the subject is appended. H. L. OLIN.

Rapid determination of iron in presence of organic substances. F. FERRARI. Pisa. *Ann. chim. applicata* 4, 341-3(1915).—To the soln. having a vol. of at least 150 cc. and contg. excess of HCl, add chlorine H_2O in small portions till the odor of Cl persists. Add a cold, clear soln. of cupferron drop by drop with const. agitation till there is an excess of at least $\frac{1}{4}$ of the amt. of reagent needed to complete pptn. of the Fe (9.01 g. Fe require 0.0833 g. cupferron). When the pulverulent ppt. has formed into large cryst. masses (after 15-20 min.), break it up with a glass rod, filter, dry with moderate air-suction, wash twice with cold H_2O acidulated with HCl, then with H_2O alone, till all acid is washed out, then treat several times with NH_4OH (to liberate the Fe compd. from the cupferron, the presence of which would be harmful during the subsequent ignition), and finally wash again with H_2O alone. Then completely dry and carefully ignite in a covered Pt crucible, and finally in the open air; weigh as Fe_2O_3 . The whole time required is not over $1\frac{1}{2}$ hrs. The method gives exact results, but is not applicable in presence of Cu, Ag, Pb, Hg, Sn, Bi, Ti, Zr, all of which form insol. salts with the cupferron. S. LEVY.

The detection of nitrates in the presence of organic matter. A. TINGLE. *J. Soc. Chem. Ind.* 35, 77-8(1916).—The method for inorg. nitrates proposed earlier (cf. *C. A.* 9, 2042), has been improved and extended to include org. nitrates mixed with org. matter. The reagent can be prepd. by dissolving 3 g. salicylic acid in 100 cc. concd. H_2SO_4 , although exact proportions are not important. A soln. of KNO_3 (0.1%) was satd. with cane sugar at lab. temp. and to 2 cc. of this sirup 2 cc. reagent were added. The mixt. was gently warmed until fuming, the charred mass boiled with 10 cc. H_2O and the resulting soln. poured off, cooled and extd. with an equal vol. of Et_2O . A portion of the ext. shaken with a little NH_4OH assumed an orange color. The remaining portion was shaken with 2 cc. FeCl_3 soln. (1%). The aq. layer slowly became red (cf. Torti, *C. A.* 9, 2126). The soln. of KNO_3 with sugar gave a negative result in testing for nitrates with Cu and H_2SO_4 . The method was also successfully applied to the detection of cellulose nitrate in a photographic film. H. M. LANCASTER.

The estimation of carbon dioxide in air by Haldane's apparatus. R. C. FREDERICK. *J. Soc. Chem. Ind.* 35, 96-9(1916).—A description of the form and the details of manipulation of Haldane's app. is followed by a simple modification applicable to higher content of CO_2 , ranging from 100-500 parts per 10,000. A propelling app. for the Hg reservoir lessens the labor of repeatedly raising and lowering the levelling bulb. H. M. LANCASTER.

Detection and determination of halogens in organic compounds. I. DROGIN AND M. A. ROSANOFF. *J. Am. Chem. Soc.* 38, 711-6(1916); cf. Bacon, *C. A.* 3, 873. —Walker and McRae's observation that B's. method gives low results (*C. A.* 5, 2055) has been confirmed; Maryott's method (*C. A.* 5, 880) gives still poorer results. A systematic study of B's. method, however, has shown that by increasing the amt. of Na by 10% and carrying out the Volhard detns. with all necessary care uniformly excellent results are obtained; in 64 consecutive detns. on PhCl , PhBr , C_6Cl_6 , $\text{C}_6\text{H}_5\text{Cl}$, *m*- and *p*- $\text{ClC}_6\text{H}_4\text{CO}_2\text{H}$, *m*- and *p*- $\text{BrC}_6\text{H}_4\text{CO}_2\text{H}$, PhCH_2Cl , α - $\text{C}_{10}\text{H}_7\text{Br}$ and CHI_3 , the

max. deviation from the calcd. was -0.31% , and in only 4 cases did it exceed 0.20% . The method is described in detail. It may also be used to detect halogens qual.; by means of it Cl can be plainly detected in 1 drop of a soln. of 1 drop CCl_4 in 30 cc. C_6H_6 .

EDGAR T. WHERRY.

Pasteur's principle of relationship between molecular and physical asymmetry. F. M. JÄGER. *Z. Kryst. Min.* 55, 209-48(1915).—Luteo-triethylenediaminecobaltisalts were used in the expts. and their relations found to agree with the postulates of Pasteur's principle. The following conclusions are drawn: There is no rational relationship between the optical orientation due to mol. asymmetry and enantiomorphic crystal structure; for the recognition of enantiomorphism of crystal structure the chem. differences of the substances is the best criterion; two influences must be differentiated, (a) that of the form not coverable by its mirror image, (b) the more or less great chem. difference of the thus orientated elements or radicals; the influence of (a) demands optical activity, that of (b) enantiomorphism of the crystal structure, and because of this, polarity of the homologous directions in the resulting crystals; in the case of asymmetric atoms there is, of course, a strong requirement or indication of Pasteur's dissymmetrical molecules; both of the indicated influences are superimposed, for where (b) is present (a) may be expected; in any case it is plain that the Pasteur phenomenon of optical activity on the one hand, and the enantiomorphism of crystallographic form and the related pyroelectric and piezoelectric conditions on the other, play unequal roles.

A. WANDTKE.

The various modifications of carborundum and the occurrence of polytypes. H. BAUMHAUER. *Z. Kryst. Min.* 55, 249-59(1915).—From his expts. B. draws the following conclusions: (1) All 3 modifications may be formed at the same time, from the same melt, and under the same conditions. (2) The 3 forms can be referred to the same axes. (3) Except for the base, there is no form that appears on all 3 at the same time. (4) Crystals of each separate type or of all 3 types intergrow with parallel axes. (5) Each type gives a different Röntgenogram (cf. following abstr.), showing a peculiar atomic or mol. structure. (6) The 3 types fall into the following crystallographic classes: types 1 and 2: trigonal hemihedral hemimorphic (ditrigonal pyramidal); 3, hexagonal hemimorphic (dihexagonal pyramidal).

A. WANDTKE.

The Röntgenograms of carborundum crystals. F. v. HAUER AND P. KOLLER. *Z. Kryst. Min.* 55, 260-3(1915).—By exptl. work H. and K. substantiate the conclusions of Baumhauer (preceding abstr.). The Röntgenograms obtained are reproduced.

A. WANDTKE.

Malachite. Remarks concerning pseudomorphic forms. R. E. LIESegang. *Z. Kryst. Min.* 55, 264-70(1915).—L. endeavors to give an explanation as to why malachite occurs as pseudomorphs, and again in reniform masses. Expts. were conducted, using NaCl crystals and AgNO_3 soln. These compds. were used because the reaction is more rapid than that between cuprite and the atmosphere. L. then shows that by using a concd. soln. of AgNO_3 , and keeping it so, and by letting it act upon a cube of salt, a pseudomorphic replacement occurs; if the soln. is not concd. a less sharp

pseudomorph is formed; if a dilute soln. be employed a shapeless replacement results. The rod-like forms of malachite are next discussed. These L. thinks are due to the formation and bursting of a semipermeable membrane, the action being entirely comparable to that of FeSO_4 in a Na silicate soln. L. concludes that the type of pseudomorph formed depends upon the concn. of the soln. and the permeability of the membrane formed at the surface of the substance which is being replaced.

A. WANDTKE.

The variable composition of melanochalcite. W. F. HUNT AND E. H. KRAUS. Univ. Mich. *Am. J. Sci.* 41, 211-4 (1916).—The sample analyzed by Koenig (cf. *Ibid* 14, 404-9 (1902)) gave CuO 76.88, SiO_2 7.80, CO_2 7.17, H_2O 7.71, ZnO 0.41, Fe_2O_3 0.07, total 100.04%. A sample from the same locality, Bisbee, Arizona, analyzed by Hunt gave CuO 88.94, SiO_2 4.31, CO_2 1.78, H_2O 4.48, ZnO 0.12, Fe_2O_3 0.22, total 99.85%. While in outward appearance these minerals are identical, the second sample gives a darker streak and a higher sp. gr., 4.704, instead of 4.141. Although admitting other interpretations, Koenig had favored the formula $\text{Cu}_3(\text{Si,C})\text{O}_4 \cdot \text{Cu}(\text{OH})_2$, a basic salt of ortho-silico-carbonic acid. Calcg. the mol. ratios from both analyses and tabulating with the mol. ratios of malachite, chrysocolla and tenorite, H. and K. find that their sample apparently consists of tenorite 68.6, chrysocolla 20.0, and malachite 11.4%; the other may have contained tenorite 30.8, chrysocolla 30.8 and malachite 38.4%. Microscopic and polariscopic examns. confirm the conclusion that melanochalcite is not a chem. compd. but a mixt. of these 3 minerals in varying proportions. L. W. RIGGS.

Origin of the zinc and lead deposits of the Joplin region. C. E. SEIBENTHAL. U. S. Geol. Survey, *Bull.* 606, 283 pp. (1915).—The geology of the region and occurrence of the ores are outlined, and the genesis of the ores is discussed in detail, both corroborative and non-corroborative evidence being reviewed. It is concluded that the ores were segregated, from disseminated Zn and Pb minerals in the Cambrian and Ordovician rocks of the Ozark uplift, by artesian-circulating alkaline-saline S-bearing waters. This view is based on: observations as to the circulation of the waters of the region; analyses of well-waters; chem. expts. which prove the competence of these waters to dissolve and transport the metals; demonstration of the presence of Zn and Pb in the waters and the reservoir sediments deposited from them, as well as in the Cambrian and Ordovician limestones, in the same ratio throughout, whereas other possible sources, such as the cryst. rocks, contain the metals in variable and quite different ratios; the relation of the ratios of sulfides of Zn, Pb and Cu to their soly. and to age relations of the deposits; the concentric arrangement of the ore deposits around the center of the structural uplift, in the order corresponding to the soly. of the sulfides of the 3 metals; the association of the ore deposition with dolomitization and silicification of the limestones; the absence of ore-deposits above an impervious shale bed, and their presence where this is absent or broken by faulting; the demonstration of a persistent ore horizon below this shale; the continuous character of the deposits where the impervious shale is absent; the occurrence of ores at depths which could only be reached by meteoric waters having artesian circulation; the presence of S in mine waters which represent most closely those depositing the ores; the occurrence of ore at the base of (impervious) Pennsylvanian rocks; the occurrence of bitumen associated with the ores, at this horizon, indicating that the solns. bearing the hydrocarbons fractionated by the shale were ascending; the association of Zn and Pb deposits with all anticlinal uplifts; the occurrence of the ores in breccias, which would favor adsorption of the metallic salts and the escape of gases from ascending solns.; the constancy of the amt. of water in deep mines independent of seasonal variations, and its connection with the number of mines, which indicate its artesian character; and calcns. as to the changes of water necessary for the concn. of the ores, which show that the NaCl content of the ground waters agrees closely with the theoretical dilution demanded.

E. T. W.

A reconnaissance in the Kofa Mountains, Arizona. EDWARD L. JONES, JR. U. S. Geol. Survey, *Bull.* 620-H, 151-64(1915).—A brief description of Au, Cu and Pb deposits associated with andesite, granite and monzonite-porphyry, respectively.

E. T. W.

Observations on certain types of chalcocite and their characteristic etch patterns. C. F. TOLMAN, JR. *Bull. Am. Inst. Mining Eng.* 1916, 401-33.—A study of the genesis of the mineral, with 40 photomicrographs.

H. L. OLIN.

The iron ores of the Philippine Islands. WALLACE E. PRATT. *Bull. Am. Inst. Mining Eng.* 1916, 247-62.—The principal deposits are: the magnetite-hematite ores of the Bulacan, Santa Inez and Camarines (cf. C. A. 10, 163) regions in southeastern Luzon, related in origin and the product of metamorphism resulting from intrusion; and the laterites of Surigao in northeastern Mindanao. The latter bear a striking resemblance to those of the Mayari district in Cuba (cf. Kemp, C. A. 9, 903) having an av. Fe content of 54%, with only a trace of P. The area covered is 40 sq. miles of which 28 are commercially important and the estd. metric tonnage is 430,000,000.

H. L. OLIN.

Potash in certain copper and gold ores. B. S. BUTLER. Note on muscovite. GEORGE STRIGER. U. S. Geol. Survey, *Bull.* 620-J, 227-36(1915).—The presence of large amts. of potash in Cu and Au ores, and the probability of its occurrence chiefly in the tailings from the concn. of the metals, is pointed out by B., many analyses being cited (cf. C. A. 10, 807). S. discusses the possible extn. of potash from muscovite, describing expts. which show that $\frac{1}{3}$ of the K present can be rendered sol. by boiling with even quite dilute HCl, and practically all by heating with NH_4Cl in a sealed glass tube to 350°.

E. T. W.

Rhode Island coal. GEORGE H. ASHLEY. U. S. Geol. Survey, *Bull.* 615, 62 pp. (1915).—Coal occurs at a number of places near Providence and Newport, R. I., but has not proved commercially workable. The rocks of the region have been subjected to intense lateral pressure, and, with the enclosed coal, have flowed and accumulated in lenses where the pressure was least. The coal has been changed in the process to high-C anthracite and even locally to graphite. Crevices in the coal are filled with asbestos and fibrous quartz. Shale has become forced into the coal, so that where it has been squeezed thinnest it contains the most ash. The coal may be classed in general as a high-ash, high-moisture, graphitic-anthracite of high sp. gr. Results of tests on a commercial scale are given.

E. T. W.

Petroleum and natural gas resources of Canada. F. G. CLAPP AND OTHERS. Canada Dept. Mines, Mines Branch, *Bull.* 291, 386 pp.(1915); cf. C. A. 8, 2246.—The stratigraphy and geological structure of the various localities and the history of the drilling operations of the wells are given, together with analyses of some oils. The oils vary much in compn.; one sample of an amber hue had a sp. gr. of 32° Baumé and contained 33.5% lubricating oil and a small % of benzene and gasoline. Another specimen known as white oil had a sp. gr. of 62° Baumé and consisted largely of gasoline, so that it could be used with satisfactory results in automobile tanks. This last evidently resulted from filtration of the lighter portions of ordinary petroleum through clay. Much of the oil is used for lubrication, as a wood-preserved, and for the manufacture of Pintsch gas. Some oil shales may become satd. with oil to such an extent that the oil oozes out in the form of springs or drippings from a mine, but will not flow or seep fast enough to yield oils in commercial quantities by drilling. Albertite is a solid bitumen representing the residuum of petroliferous seepages; it occurs in veins, is a jet-black, shiny mineral, and is classed among the indications of oil. Where geological formations rise in a certain direction and disappear by thinning out, one is likely to find an ideal structure for the accumulation of natural

gas. Other conditions favoring this are: a porous formation to hold the gas, an impervious overlying structure to prevent its escaping, and suitable geological structure to form a reservoir for it. One sample of gas reported consisted of 92.2% hydrocarbons, 5.6% N, 1.4% CO₂, and traces of O, H, CO, H₂S. Statistics showing the valuation of oil and of natural gas produced in the different provinces during the past 14 years are given. The government laws relating to gas and oil production and disposal are added in an appendix.

R. L. SIBLEY.

Magmatic differentiation in effusive rocks. SIDNEY POWERS AND ALFRED C. LANE. *Bull. Am. Inst. Mining Eng.* 1916, 535-48.—The paper presents the results of an investigation of the gravimetric differentiation in lava flows based on quant. microscopic and chem. study of a Triassic basalt from Nova Scotia, confirmed by data from a study of certain Keweenaw ophites. Results show a concn. of the leucocratic, felsic constituents at the top of the flow, and the melanocratic, mafic constituents at the base. The quickly chilled top and bottom show, when free from alteration, the original compn. of the magma. The grain of the rock in thick flows varies with depth and is greatest just below the center where cooling takes place most slowly, although the study is made difficult by the presence of several generations of crystals due to convection currents and the subsidence of partially cooled upper portions of the flow.

H. L. OLIN.

Petrography of the Hühnberg rocks between Schnalkalden and Friedrichroda. A. UTENDÖRFER. *Centr. Min. Geol.* 1915, 623-31, 642-9.—The rocks are stated to be intrusives, and U. believes that they were consolidated at not more than 500 meters depth. These rocks, having the mineral nature of a diabase, are characterized by a development of primary quartz, which U. thinks is due to the assimilation of the red sandstone into which the rocks were intruded. The rocks also show interstitial glass. The age of the intrusives is Permian.

A. WANDTKE.

Inorganic constituents of alcyonaria. F. W. CLARKE AND W. C. WHEELER. U. S. Geol. Survey. *Proc. Nat. Acad. Sci.* 1, 552-6(1915).—The figures of 22 analyses are given showing the inorganic compn. of 20 species, representing 17 genera of alcyonarians. The localities from which the specimens were obtained, and in some cases the depth and temp. of the water, are given. In 18 specimens the amt. of organic matter ranged from 13 to 61%, the remaining 4 containing very little. In the tables the organic portion is rejected and the remaining inorganic portion calcd. to 100%. Excluding 2 erratic specimens and arranging the results in the order of ascending MgCO₃ content, a remarkable relation appears, connecting compn. with the temp. of the habitat. Those north of Lat. 40° N. contain from 6.18 to 9.05% MgCO₃, while species between 33° N. and 8° S. contain from 11.56 to 15.73%. Species from cold northern or very deep tropical waters contain less MgCO₃ than those from warm waters. The same relation appeared in the analyses of echinoderms (*C. A.* 9, 1023). It is also noteworthy that the higher proportions of Ca₃P₂O₈ are commonly associated with high values for Mg.

WILLIAM BRADY, WILLIAM T. HALL.

Interpretation of assay curves for drill holes. EDWARD H. PERRY AND AUGUSTUS LOCKE. *Bull. Am. Inst. Mining Eng.* 1916, 195-201.—In the exploration of a Cu

deposit by drilling, distinction must be made between primary and secondary ore. The first may extend downward indefinitely and fluctuate independently of depth while the latter has a limited vertical extent since enrichment decreases downward. If, therefore, in drilling, a hole descends from profitable ore to that below the commercial minimum, the question of further operation depends upon the genesis of the deposit. If primary, wt. must be given to the possibility of improvement with depth. Curves made by plotting assays against depths are helpful in detg. the character of the ores.

H. L. OLIN.

Chemistry of furnace efficiency and air supply. C. E. LUCKE AND E. D. THURSTON. *School Mines Quart.* 36, 326-30(1915).—Furnace efficiency = 1 — (loss on combustion/"heat originally in fuel"). The general equation which the authors develop is: Furnace efficiency = $1 - (C' / (CO_2 + CO)) [(10193 CO + 8702 H_2 + 28578 CH_4) / (51892 - 37348 C')]$. C' = the fractional part by wt. of the combustible existing as C, free or combined. The values of CO, CO₂, H₂ and CH₄ are obtained from the flue gas analysis.

L. P. WEBBERY.

The operation of the blast furnace. J. E. JOHNSON, JR. *Met. Chem. Eng.* 14, 210-5(1916).—J. recognizes 4 zones through which the raw materials pass: (1) drying and warming; (2) reduction of the ore, calcination of the stone and soln. of some C; (3) incipient fusion and the beginning of slag formation; (4) the reduction of the ore remaining in the slag, the final carbonization of the Fe and the addition of Si, P and Mn. While the use of crushed stone is generally preferable, slipping caused by the deposition of carbon dust may sometimes be prevented by using lumpy stone which calcines at lower levels, i. e., those at which C is pptd., and removes the obstructing C through the solvent action of the CO₂ liberated. Fine sandy ores like the Mesabi require higher fuel consumption than the lumpy Old-Range because of their extremely intimate contact with the coke which results in high soln. losses and lowered efficiencies (cf. C. A. 10, 445). For the successful operation of the furnace the slag in the final stage must reach the temp. required to set free the Fe it contains and to render it sufficiently fluid to cover the coke and absorb the S as soon as it is liberated, thereby keeping it out of the Fe.

H. L. OLIN.

Modern development in the combustion of blast-furnace gas with special reference to the Bradshaw gas burner. K. HEUSSENER. *Bull. Am. Inst. Mining Eng.* 1916, 443-74; cf. C. A. 9, 1838.—H. surveys the principles involved in the combustion of blast-furnace gas in boilers and stoves. The concurrent development of the steam engine and steam turbine and the inability of the gas engine to maintain a high efficiency except with high and const. load have brought about a revival of interest in the use of gas for steam production. The problems of successful gas burning under varying pressure of top gas is solved in the Bradshaw burner by the application of the Venturi principle which maintains a const. ratio of gas and air. Under given conditions efficiencies depend upon the boiler loads; with loads of 100% an efficiency of 80% is possible and it need not drop further than 75% with higher loads. Gas washing is profitable for stoves but losses usually occur where it is done for boilers. The best temp. for washing is 100° F.

H. L. OLIN.

Coal-dust firing in reverberatory furnaces. C. R. KUZELL. *Eng. Mining J.* 101, 302-6(1916).—Mainly a summary of descriptions and facts already published. Coal-dust firing of reverberatories was adapted from cement-kiln firing practice. The grade of coal permissible is not fixed by close limits, but the coal must be dried sufficiently so that it will be easily suspended in the air blast, but not dry enough to make spontaneous combustion likely. Coal is pulverized so that 90% will pass 100- and 80% pass 200-mesh. The blast pressure varies from 8 to 16 oz. per sq. in. Furnaces of

capacity 400 to 700 tons ore per day burn 60 to 100 tons of coal dust. Improved new charging methods largely obviate fettling and necessitate relocation of matte-tap holes. Furnace repairs are less costly than in the older firing practice. Diagrams, flow sheet of coal-pulverizing plant, and a bibliography are given. F. W. S.

The chemical evidence of smelter smoke injury to vegetation. J. P. MITCHELL. *J. Ind. Eng. Chem.* 8, 175-6(1916).—Expts. were made in turn on potted plants in small cabinets, plants in green-houses and finally on vegetation under field conditions to det. the effects of various constituents of smelter smoke. The action of SO_2 is distinctly different from that of SO_3 or H_2SO_4 . The latter destroys the plant tissue, causing brown or black "burns" while SO_2 , less immediately destructive, on being absorbed by the plant combines chemically with some constituent and finally interferes with the normal physiological processes. Chemical evidence of the deposition of poisons like Pb and As on the surface of plants is easily obtained; evidence of the activity of SO_2 is less apparent. High S values indicate exposure to the gas but absorption of S from the soil is a possibility and to eliminate error from this source proceed by 3 steps; (1) det. the S content of the vegetation in question; (2) compare results with those obtained from similar plants not exposed to SO_2 fumes; (3) det. the S content of the soil in which sample of vegetation grew. Results based on this procedure have been uniformly satisfactory and in accord with botanical studies in the same districts.

H. L. OLIN.

The prevention of hydrolysis in cyanide solutions. H. M. LESLIE. *J. Chem. Met. Soc. S. Africa* 16, 77-9, 110-3(1915); cf. *C. A.* 10, 165.—**Discussion.** W. A. CALDSCOTT. The hydrolysis consists of the interaction of KCN and CaO with H_2O forming HCNO; this will decompose, giving humus-like products, some of them insol. and extremely difficult of estn. It is desirable to know whether the proportion of protective alkali is a const., or the losses are influenced by light and other conditions. J. WARSON describes expts. with two sep. halves of the same soln., one closed, the other open. In 73 days, the loss (as KCN) in the open was 62.72%, in the closed, 6.57%. The alkalinity diminished in the open test, and increased by a few thousandths in the closed test. On the theory of hydrolysis, increase should have been over 0.1. Existence of hydrolysis is not proved. A. WHITBY gives expts. pointing to increase of Zn in soln. and its subsequent deposition as insol. compds. in the changes under discussion. It is necessary to consider the interactions of KCN, CaO, Zn and of atmospheric influences.

Specifications for alloys for high-speed superheated steam turbine blading. W. B. PARKER. *Inst. of Metals*, Sept. 1915, 47 pp. (adv. proof); *J. Soc. Chem. Ind.* 34, 1015-6; *Metal Ind.* 14, 68-71, 114-6(1916).—Material used in blading high-speed turbines driven by superheated steam should satisfy the following requirements: It should be in a physically stable condition, free from internal stresses, non-corroding in damp steam, and resisting steam erosion. The proportionality limit (i. e., the point at which the elongation ceases to be proportional to the load) should be at least 10 tons per sq. in., and should remain const. within 10% over the whole range of 100-400°. The max. stress should be at least twice the proportionality limit, and remain const. over the same range of temp. The greater the natural hardness of the metal in the soft or annealed condition the better; 30° by Shore's scleroscope would be desirable. The thermal expansion should preferably be low, with a const. coeff. between 100° and 500°. Ductility is not of special importance, while low sp. gr. would be an advantage. Definitions are given of the terms used in describing the phys. properties of alloys, together with a list of non-ferrous alloys used, or formerly used, in the manuf. of blades. Brass is too soft and anneals readily in superheated steam. Pure Cu is suitable, while pure Ni free from C is difficult to obtain. Co has not been suffi-

siently investigated. Pure Monel metal (Cu-Ni) may be used for stationary blades under certain conditions. Al-bronze anneals readily, like brass. Cu-Al-Mn and Cu-Al-Ni alloys, rich in Cu, may repay further investigation. The most useful alloy up to the present is pure P-bronze. Alloy steels are being used chiefly for want of a better non-ferrous material, in spite of their common tendency to rust. E. J. C.

The nickel chromium alloys patent situation. ANON. *Elec. World* 67, 80-1 (1916).—A brief account of the patent situation covering the Ni-Cr resistance wires.

Crucible melting furnace. EUGEN STOLL and J. ENGEL. Ger., 286,027, Feb. 3, 1914.

Grate plate for blast crucible melting furnaces. ERNST BRABANDT. Ger., 285,998, June 11, 1914. The plate is provided with peripheral transverse incisions.

Charging machine for metallurgical furnaces. C. MEHLER, MASCHINENBAU-ANSTALT, G. M. B. H. Ger., 286,063, Mar. 27, 1914. The charge is introduced by centrifugation.

Charging blast furnaces. H. STÄHLER. Ger., 284,757, Oct. 31, 1913.

Device for operating the charging bell of blast furnaces. J. POHLIG. AKT.-GES. and A. KÜPPERS. Ger., 286,149, Mar. 10, 1914.

Pouring machine for a plurality of blast furnaces. DEUTSCHE MASCHINENFABRIK AKT.-GES. Ger., 285,359, Feb. 23, 1913. Cf. C. A. 9, 2377.

Worm driven tilting device for casting pans. SIEG-RHEINISCHE LOKOMOTIV- UND MASCHINENFABRIK G. M. B. H. Ger., 285,388, June 16, 1914.

Device for removing the accumulations at the mouth of converters. JÜNKER-RÄTHER GEWERKSCHAFT. Ger., 285,611, May 27, 1914.

Operating regenerative metallurgical furnaces. J. E. BELL. U. S., 1,170,397, Feb. 1. Air heated in a regenerator is mixed with pulverized solid fuel which is burned in suspension to form producer gas, with which additional air is then mixed to form fuel for use in the furnace. The temp. produced in the combustion chamber is regulated by injecting steam if desired.

Apparatus for sintering and smelting iron and other ores. A. S. DWIGHT. U. S., 1,169,384, Jan. 25. The ore is first sintered into a continuous cake upon a moving platform and then the cake is passed between electrodes, one of which is in contact with the cake, to heat it further before passing to a smelting zone.

Blast furnace for roasting ores, waste and foundry products. W. BUDAUS. Ger., 285,888, Oct. 12, 1913.

Apparatus for breaking up and preparing ores for wet dressing. COPPER PROCESS Co. Ger., 285,767, Aug. 28, 1913. A large part of the gang, together with the fine metallic particles, is prevented from going into the slime.

Slime hearth for dressing ores, coal. DEISTER MACHINE CO. Ger., 285,909, Feb. 10, 1914. Cf. C. A. 9, 1601.

Apparatus for hardening files. F. KÜRSCHNER. Ger., 286,126, June 12, 1914.

Drying air for metallurgical use. W. WENSE. U. S., 1,169,371, Jan. 25. Air is purified and dried by first removing CO₂ and then passing the air through a shower of a strong soln. of NaOH.

Volatilizing constituents of ores. S. I. CLAWSON. U. S., 1,169,530, Jan. 25. Crushed ore is treated in a heated chamber with Cl and with a current of N which carries off the volatile compds. formed. These are passed to a fume arrester where most of the volatile compds. are sepd. and the N with some of the volatilized compds. still mixed with it is combined with additional Cl and returned to the ore-treatment chamber.

Concentrating ores. E. H. NUTTER. U. S., 1,170,665, Feb. 8. Finely crushed ore, *e. g.*, Cu ore tailings, is mixed with H_2O and a small amt. of acid sludge from petroleum refining and the mixt. is aerated and agitated to form a froth which is then sepd. after heating to 36° . Wood creosote may also be added to assist in the flotation.

Agglomerating fine ores. SELAS AKT.-GES. Ger., 285,913, Apr. 24, 1914. The fine ore, mixed with coke, is fed on to a moving grating which passes under a blast and over a suction box.

Concentrating ores. A. H. HIGGINS. U. S., 1,170,637, Feb. 8. Finely crushed ore, *e. g.*, Zn ore containing Pb, is mixed with H_2O and with a small amt. of sulfonated castor oil and the froth which is produced by aeration and agitation of the mixt. is sepd. β -Naphthol or olive oil may also be treated with H_2SO_4 to form the frothing agent. Cf. C. A. 10, 586.

Recovering metals from sulfides. U. WEDGE. U. S., 1,169,444, Jan. 25. Sulfide ores of Fe, Zn, etc., are heated to a temp. sufficient to volatilize S, in an atm. containing CO_2 or only 4-6% O or other gas which will promote the oxidation of the metal without oxidizing the S and the oxide thus formed is exposed to a reducing atm. to obtain the free metal.

Roasting ores. U. WEDGE. U. S., 1,170,375, Feb. 1. Ore, *e. g.*, sulfide ore, is roasted successively on hearths in 2 different stages. In the first stage heated air is supplied to the ore to burn the combustible constituents of the ore; combustion gases from the second stage are not allowed to come into contact with ore in the first stage of roasting. The gases formed may be used in making H_2SO_4 . In the second stage, combustion gases formed outside the roasting furnace are introduced into the charge and the hot gases from the second stage of roasting are used to preheat the air used in the first stage.

Ore-roasting furnace. U. WEDGE. U. S., 1,170,376, Feb. 1. Superposed hearths are arranged to carry out the roasting method of U. S. pat., 1,170,375 (*supra*).

Smelting fine ores. A. S. DWIGHT. U. S., 1,169,139, Jan. 25. Finely divided ores, *e. g.*, of Pb or Fe, are formed into coherent and rigid but highly porous cakes by sintering and are then subjected to the action of CO and smelted in a reverberatory furnace. Sintered cakes of Fe_3O_4 may be oxidized to Fe_2O_3 (for use in open hearth decarburization of steel) by treatment with steam.

Tin. J. RUEB. Brit., 20,609, Oct. 6, 1914. In smelting Sn ores, concentrates, slags, tin-plate waste, etc., with pyrites to obtain a tin-iron mat, as described in 27,145, 1912 (C. A. 8, 1561), lime or $CaSO_4$ is added to the charge to increase the % of Sn in the mat.

Apparatus for treating silver ores E. LANGGUTH. U. S., 1,169,270, Jan. 25. An ore of Ag, which may also contain Au, Pb or Zn, is heated with $ZnCl_2$ in the vat *a* to decompose the ore. Pb (preferably carrying Ag) is added in this vat to take out the Au and the main portion of Ag present. The remainder of the Ag and a

small part of the Pb is extd. in the vat *b* by addition of Zn and the main part of the Pb is quantitatively pptd. in the vat *c* by addition of Zn. The Pb from the vat *b*, carrying some Ag, may be used for the first desilverization of the charge in vat *a*.

Superficial oxidation of iron and steel. B. GUERINI. U. S., 1,169,397, Jan. 25. Fe or steel articles, *e. g.*, tools or gun barrels, are immersed in a soln. of Na picrate and NaOH and the bath is gradually heated to about 130–150° while the articles are subjected to its action to produce an oxidized surface.

Iron and steel. A. E. DAVIES. Brit., 20,582, Oct. 6, 1914. In a basic open-hearth process, the furnace lining is coated with the finishing slag; after tapping the metal, by tilting the furnace backwards and forwards repeatedly, the slag is enriched and thickened by additions of lime and Fe ore and oxides.

Zinc. F. THARALDSEN. Ger., 286,229, Mar. 31, 1914. Addition to 261,188 (C. A. 7, 3310). In the practical application of the principal process, according to which the charge is introduced under a liquid slag, a not inconsiderable amt. of the Zn has been found to be retained by the slag, in part mechanically and in part chem. In order to recover the Zn from this slag bath the latter is drawn off periodically into a slag vat and the Zn therein is reduced by the introduction of a reducing agent. This vat is provided with a distn. head, and the Zn vapors are drawn off and condensed in the usual manner.

Briquetting ores. E. MILLINGTON and KITTEL & Co. Brit., 20,832, Oct. 10, 1914. Finely divided ore is mixed with coal dust or charcoal and flux, and moistened with tar or pitch, and the mixt. is pressed into briquets, which are coked at a temp. of 700–850°, and cooled, before use in an elec. or other reduction furnace.

Remelting ferromanganese and like alloys. ROMBACHER HÜTTENWERKE and J. I. BRONN. Ger., 285,956, Nov. 5, 1910. An elec. hearth furnace is used, with a clearly visible bath surface and electrodes extending down from above. Between each of the movable mounted electrode blocks and the molten bath a fall of less than 30 v. is secured by using a suitable current and adjusting the electrode very close to the surface of the bath.

Hard copper alloy. F. C. FRARY and S. N. TEMPLE. U. S., 1,169,392, Jan. 25. An alloy for making castings which are free from blow holes is formed of Cu 99 and Ca, Ba, Sr or Mg 1%.

Uniting copper to steel. W. M. PAGE. U. S., 1,171,066, Feb. 8. Molten Cu is treated with about 2% its wt. of Fe and with P to prevent oxidation. A steel billet is dipped in the bath of deoxidized Cu-Fe alloy thus produced and pure Cu is subsequently cast on the billet carrying a film of the Cu-Fe alloy.

Alloy for castings. E. D. GLEASON. U. S., 1,169,536, Jan. 25. Cu is combined with a fusion product of CaF₂ and H₂BO₃ to obtain castings free from O or other gases.

Ore-amalgamator. J. E. DICK. U. S., 1,169,740, Jan. 25.

Alloy for jewelry, scientific instruments, etc. R. J. PESCHKO. U. S., 1,169,753, Jan. 25. An alloy of Au 60, Pt 10 and Pd 30 parts is hardened by addition of 0.1–2% of Ir.

Sherardizing. E. F. COLLINS and J. A. CAPP. U. S., 1,169,529, Jan. 25. During sherardizing, the temp. is maintained at 350–375° and a Zn dust of 80–92% purity is used. A firmly adherent coating is obtained which will not crack, flake or peel off when the coated articles are bent or swaged. The Zn should be free from Pb and contain little matter except Zn and ZnO.

Coating articles with atomized metal. METALLISATOR. Ger., 285,823, Sept. 13, 1912. Construction of a suitable app. is specified.

10. ORGANIC CHEMISTRY.

CHAS. A. ROULLER.

N-Halogen derivatives of the *p*-halogen-substituted benzenesulfonamides. ROBERT R. BAXTER AND FREDERICK D. CHATTAWAY. *J. Chem. Soc.* 107, 1814-23 (1915).—The recent employment in the treatment of infected wounds (Dakin, *Brit. Med. J.* Aug. 28, 1915) of the sol. Na salts of sulfonmonochloroamides described by C. (J. Chem. Soc. 87, 145 (1905)) has made it seem desirable to extend the series. The dichloroamides are produced as follows: $\text{ArSO}_2\text{NH}_2 + 2\text{HOCl} \longrightarrow \text{ArSO}_2\text{NCl}_2 + 2\text{H}_2\text{O}$, and react with alk. hydroxides to form the salts $\text{ArSO}(\text{ONa})\text{:NCl}$, which are, according to D., powerful, practically non-irritating antiseptics. The required Na sulfonates were prepd. by slowly adding, with stirring, PhCl , PhBr , and PhI to fuming H_2SO_4 (d. 1.9, 10% free SO_3) in slight excess, keeping the temp. below 60° ; after 1 hr. the cooled mixt. is slowly run into 6 vols. satd. NaCl soln. at 0° , the $p\text{-XC}_6\text{H}_4\text{SO}_2\text{Na}$ sepg. with some NaCl , which is left behind on drying and extg. with hot alc. A small amt. of the sulfone crysts. from the alc. with the Na salt, and is removed by washing with Et_2O . The Na salts are ground up with 1.25-1.5 mols. PCl_5 , heated 0.5 hr. on the H_2O bath, cooled, poured onto ice, washed with ice- H_2O , taken up with Et_2O , this dried and evapd., leaving the chlorides as oils which solidify on cooling, and are converted into the amides by adding to cooled 1:1 aq. NH_3 . For the prepn. of the *N*-halogen derivs., see C.'s 1st paper. *p*-Chlorobenzenesulfondichloroamide, prisms, m. 83° ; potassium *p*-chlorobenzenesulfonchloroamide, prisms with 1 H_2O , loses H_2O on heating and decomps. violently, at about 160° ; sodium salt, prisms, with 1 H_2O , decomps. violently at about 190° ; *p*- $\text{ClC}_6\text{H}_4\text{SO}_2\text{NBr}_2$, pale yellow prisms, m. 102° ; *p*- $\text{BrC}_6\text{H}_4\text{SO}_2\text{NCl}_2$, m. 108° , not 106° (Kastle, Keiser, and Bradley, *Am. Chem. J.* 18, 493 (1896)); potassium *p*-bromobenzenesulfonchloroamide, needles with 1 H_2O , explodes 165° ; sodium salt, needles with 1 H_2O , explodes, with previous fusion, at 178° ; *p*-bromobenzenesulfondibromoamide, pale yellow prisms, m. $132-3^\circ$ (decompn.); potassium *p*-bromobenzenesulfonbromoamide, needles with 1 H_2O , explodes 193° ; sodium salt, needles with 1 H_2O , explodes 211° ; *p*-Iodobenzenesulfondichloroamide, prisms, m. 147° ; potassium *p*-iodobenzenesulfonchloroamide, needles with 1 H_2O , explodes 150° ; sodium salt, plates with 1 H_2O , explodes 185° . The above decompn. pts. were obtained on rapid heating. In the presence of $\text{C}_6\text{H}_5\text{N}$, the sulfonyl chlorides reacted readily in Et_2O with amines to form substituted amides and anilides, all of which yield *N*-halogen derivs. *p*-Chlorobenzenesulfonmethylanilide, plates, m. 59° ; chloroamide, $\text{ClC}_6\text{H}_4\text{SO}_2\text{NClMe}$, prisms, m. 66° ; bromoamide, pale yellow prisms, m. 99° ; *p*-chlorobenzenesulfonbenzylanilide, needles, m. $108-9^\circ$; chloroamide, prisms, m. 124° ; bromoamide, pale yellow prisms, m. 112° . In the case of the anilides, the Et_2O is distd. off, and the reaction completed by heating for a short time on the H_2O bath. In cases in which intramol. rearrangement may occur in the prepn. of the chloroamides, the free HOCl is best liberated by means of KHCO_3 . The anilides were all analyzed by conversion into the chloroamides, purifying these by recrystn. from a mixt. of CHCl_3 and light petroleum, and estimating the *N*-halogen by its power to replace I. *p*-Chlorobenzenesulfonphenylchloroamide, prisms, m. 100° ; *p*-bromobenzenesulfonphenylchloroamide, prisms, m. 104° ; *p*-iodobenzenesulfonphenylchloroamide, rhombs, m. $139-40^\circ$. *p*-Chlorobenzenesulfon-*m*-chloroanilide, rhombs, m. 106° , chlorophenylchloroamide, prisms, m. 90° ; *p*-chloroanilide, needles, m. 148° ; *p*-chlorophenylchloroamide, prisms, m. 127° ; 2,4-dichloroanilide, plates, m. 108° ; 2,4-dichlorophenylchloroamide, prisms, m. 100° ; *p*-bromoanilide, prisms, m. 163° ; *p*-bromophenylchloroamide, prisms, m. 127° ; 2,4-dibromoanilide, prisms, m. 116° ; 2,4-dibromophenylchloroamide, prisms, m. 110° (decompn.); *p*-iodoanilide, needles, m. 173° ; *p*-iodophenylchloroamide, m. 70° (decompn.), decomps. not even

for a few min. at room temp.; *o*-nitroanilide, pale yellow prisms, m. 114° (decompn.); *o*-nitrophenylchloroamide, faintly yellow prisms, m. 148° (decompn.); *m*-nitroanilide, pale yellow needles, m. 124°; *m*-nitrophenylchloroamide, very faintly yellow prisms, m. 131° (decompn.); *p*-nitroanilide, yellow needles, m. 159° (decompn.); *p*-nitrophenylchloroamide, very faintly yellow prisms, m. 143° (decompn.); *o*-toluidide, needles, m. 111°; *o*-tolylchloroamide, prisms, m. 127° (decompn.); *p*-toluidide, prisms, m. 88°; *p*-tolylchloroamide, prisms, m. 110° (decompn.); *p*-tolylbromoamide, pale yellow prisms, m. 91°. *p*-Bromobenzenesulfon-*p*-chloroanilide, prisms, m. 138°; *p*-chlorophenylchloroamide, prisms, m. 142°; 2,4-dichloroanilide, prisms, m. 134°; 2,4-dichlorophenylchloroamide, prisms, m. 97°; *p*-bromoanilide, prisms, m. 141°; *p*-bromophenylchloroamide, prisms, m. 141°; 2,4-dibromoanilide, prisms, m. 147°; 2,4-dibromophenylchloroamide, prisms, m. 117°; *p*-iodoanilide, prisms, m. 160° (decompn.); *p*-iodophenylchloroamide, decomps. in a few min. at room temp., decomps. completely below 100°; *o*-nitroanilide, yellow needles, m. 130°; *o*-nitrophenylchloroamide, faintly yellow prisms, m. 160° (decompn.); *m*-nitroanilide, yellow needles, m. 140°; *m*-nitrophenylchloroamide, yellow prisms, m. 140° (decompn.); *p*-nitroanilide, yellow needles, m. 183°; *p*-nitrophenylchloroamide, pale yellow prisms, m. 164°; *o*-toluidide, prisms, m. 119°; *o*-tolylchloroamide, prisms, m. 129° (decompn.); *p*-toluidide, prisms, m. 99°; *p*-tolylchloroamide, prisms, m. 131°. *p*-Iodobenzenesulfon-*p*-bromoanilide, plates, m. 174°; *p*-bromophenylchloroamide, prisms, m. 137° (decompn.); *p*-iodoanilide, plates, m. 167° (decompn.); *p*-iodophenylchloroamide, prisms, m. and decomps. 142° when rapidly heated, begins to decomp. after keeping a few min. at room temp.; *o*-nitroanilide, faintly yellow plates, m. 137°; *o*-nitrophenylchloroamide, faintly yellow prisms, m. 167°; *m*-nitroanilide, yellow prisms, m. 157°; *m*-nitrophenylchloroamide, faintly yellow prisms, m. 164°; *p*-nitroanilide, faintly yellow plates, m. 154°; *o*-toluidide, plates, m. 161°; *o*-tolylchloroamide, prisms, m. 110°; *p*-toluidide, prisms, m. 135°; *p*-tolylchloroamide, prisms, m. 137° (decompn.).

M. HEIDELBERGER.

Hydrazides of cyanoacetic, isonitrosocyanoacetic and nitrocycanoacetic acids.
A. DARAPSKY AND D. HILLERS. *J. prakt. Chem.* 92, 297-341 (1915).—Angeli has shown (cf. *Gazz. chim. ital.* 23, II, 101 (1893)) that $N_2H_4 \cdot H_2O$ forms a cryst. addition product with $(CN)_2$ in H_2O , which reacts energetically with aldehydes and ketones. The same compd. was obtained by Curtius and Dedichen (cf. *J. prakt. Chem.* 50, 245 (1894)) and called "Carbohydrazinin." C. and D. also found that $N_2H_4 \cdot H_2O$ and nitriles at higher temps. formed "hydrazincarbimines," which Pinner (cf. *Ber.* 27, 3274 (1894)) showed to be identical with isodihydratetrazines, and which Bülow (cf. *Ber.* 39, 2618, 4106 (1906)) calls "*N*-aminotriazoles." A monohydrazidine, $RC(:NH)NHNH_2$, is first formed which reacts with another mol. of the nitrile, giving a dihydrazidine, $[RC(:NH)NH]_2$. The latter further reacts with $N_2H_4 \cdot H_2O$, losing 2 NH_3 with the

formation of a *N*-aminotriazole, $H_2NN \cdot CR:N:N:CR$, and a trace of the isomeric di-

hydratetrazine, $HN \cdot CR:N:N:CR \cdot NH$. $NCCH_2CO_2Me$ reacts with $N_2H_4 \cdot H_2O$ in only 1 way, giving cyanoacethydrazide (a), $NCCH_2CONHNH_2$, which with $NaNO_2$ forms cyanoacetazide (b), $NCCH_2CON_2$. On heating with alc. (b) yields cyanomethylurethan, $NCCH_2NHCO_2R$, which on hydrolysis yields glycine, identical with that obtained from $ClCH_2CO_2Et + NH_3$, thus proving the equivalency of the 2 valencies of the Me C atom in $AcOH$ attached to Cl and CO_2H , resp. (a), prepd. by boiling 60 g. $N_2H_4 \cdot H_2O$ with 99 g. $NCCH_2CO_2Me$ in 5 vols. abs. alc. for 1 hr., long prisms, m. 114.5-15°. The HCl deriv., obtained by adding $Et_2O \cdot HCl$ to (a) in 10 vols. warm abs. alc., m. 145°, fine, white ppt. It was converted, by dissolving in H_2O , covering with Et_2O , adding shaking and evapg. the Et_2O ext., into (b), pale yellow, explosive in Et_2O it gave cyanoacetanilide, white leaves

from alc., m. 198.5-200°. On boiling (b), obtained from 6.8 g. of (a) (HCl deriv.), in 34 cc. abs. alc. until evolution of N ceased (1 hr.), and distg. off the alc., *cyanomethylurethan* was obtained as an oil which gradually crystd., lustrous needles or prisms from ligroin, m. 145°. On hydrolysis with 20% HCl it gave $\text{H}_2\text{NCH}_2\text{CO}_2\text{H}$ and NH_4Cl . *Methyl isonitrosocynoacetate hydrasine salt*, $\text{NCC}(:\text{NON}_2\text{H}_3)\text{CO}_2\text{Me}$, was obtained by adding 0.5 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ to 1.28 g. $\text{NCC}(:\text{NOH})\text{CO}_2\text{Me}$ in 2 vols. alc. at room temp., yellow cryst. ppt., sinters 78°, decomp. 100°. With BzH it yields benzaldazine. By further action of $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ on the above salt, by short warming on a H_2O bath, *isonitrosocynoacethydraside hydrasine salt* (c), $\text{NCC}(:\text{NON}_2\text{H}_3)\text{CONHNH}_2$, was formed, beautiful yellow needles from alc., decomp. 135°; with FeSO_4 it gave a deep violet color which is permanent after addition of NaOH: *silver salt*, brown ppt.; *lead salt*, brown ppt. By decomp. (c) in H_2O with the calcd. amt. of HCl the free *isonitrosocynoacethydraside* (d) was obtained, brown, lustrous leaves, decomp. 166°. (d) possesses amphoteric properties due to the presence of the acid (:NOH) and basic (NHNH_2) groups, so that with warm $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in H_2O it forms the original salt, and with HCl a *hydrochloride*, yellow, cryst. ppt., decomp. 204°. *Benzalisonitrosocynoacethydraside*, prepd. by slowly adding 3.18 g. BzH to 1.6 g. of (c) in 32 cc. H_2O , pale yellow needles from alc., decomp. 148°. Benzaldazine was also formed, and was sepd. by extrn. with Et_2O . The same benzal deriv. was also obtained from (d) and BzH. It is pptd. unchanged from alkalis by acids. Me_3CO reacts vigorously with (c), forming the *acetone derivative*, $\text{NCC}(:\text{NOH})\text{CONHN}:\text{CMe}_3$, bright yellow crystals, m. 205°. Some bisdimethylazimethylene was also formed. On mixing 2.8 g. NaNO_2 in H_2O with 3.2 g. (c) in H_2O , covering with a layer of Et_2O , then gradually adding with cooling and shaking 7.3 cc. HCl (d. 1.10), and evapg. the Et_2O ext., *isonitrosocynoacetamide* (e), $\text{NCC}(:\text{NOH})\text{CONH}_2$, was obtained, yellow oil which soon crystd., explodes on heating. Yield, 79%. It reacts with PhNH_2 on standing in Et_2O for 2 days, forming an anilide, identical with the cyanoximidoacetanilide obtained by Dimroth and Dienstbach (cf. C. A. 3, 536). On boiling with abs. alc. until evolution of N ceased it gave *isonitrosocyanomethylurethan*, $\text{NCC}(:\text{NOH})\text{NHCO}_2\text{Et}$, crystals from C_6H_6 , m. 96-7°. Hydrolysis with concd. HCl gave CO_2 , NH_3 , NH_2OH and $(\text{CO}_2\text{H})_2$. *Methyl nitrocynoacetate potassium salt*, $\text{NCC}(:\text{NO}_2\text{K})\text{CO}_2\text{Me}$, was prepd. by gently warming 38.4 g. of $\text{NCC}(:\text{NOH})\text{CO}_2\text{Me}$ in 100 cc. H_2O with 1 l. N KMnO_4 , lustrous leaves from H_2O , m. 264-6° (decompn.) (yield 57%); with AgNO_3 it gave a *silver salt*, which when decompd. with H_2S yielded *methyl nitrocynoacetate*, $\text{NCCH}(\text{NO}_2)\text{CO}_2\text{Me}\cdot\text{H}_2\text{O}$, lustrous needles, m. 76°. With KOH it forms the original K salt, and with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in warm MeOH the corresponding *hydrasine salt*, crystals, m. 168°. Further action of $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ converts it into *nitrocynoacethydraside hydrasine salt*, silky needles, sinters 140°, decomp. 200°. On shaking with an excess of BzH, benzaldazine together with a red N_2H_4 salt was obtained. *Nitrocynoacethydraside potassium salt* was obtained by gently warming 9.1 g. $\text{NCC}(:\text{NO}_2\text{K})\text{CO}_2\text{Me}$ with 10 g. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ in 40 cc. H_2O , long, stellar prisms, explodes on heating. *Nitrocynoacethydraside* was obtained in 2 forms: (1) *anhydrous* (f) by adding dil. HCl to the N_2H_4 salt in H_2O , and (2) *hydrated* (g), in a similar way from the K salt. Prepd. by the latter method, it contains 1 H_2O which is not expelled *in vacuo* over H_2SO_4 , nor by heating at 110-20°, but on boiling in H_2O , the soln. becomes yellow and (f) seps., short, yellow prisms. Both forms darken but do not m. below 285°. (g) becomes dark red when boiled with 3 N NaOH, and is pptd. chiefly in the anhydrous form on addition of dil. HCl. Boiling concd. HCl has no effect on (g). (f) forms an isomeric series of salts, colorless or leuco, and colored or chromo salts. The white N_2H_4 salt can also be prepd., besides the method given above, by triturating (g) with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$. The *red salt* prepd. by adding 3 cc. $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ to (f), warming gently and adding several vols. of abs. alc. to the intensely red liquid, sinters 185-95°, decomp. 200°, orange crystals; with dil. HCl (f) is regenerated. By

adding a slight excess of NH_4OH to (g) the *white monoammonium salt* is formed, needles. The corresponding *red salt* was prepd. by dropping NH_4OH into 0.72 g. (f), suspended in 4 cc. H_2O , until the liquid became red, and then gently warming and finally concg. to about 0.33 of the original vol., long, orange needles. Neither form m. below 275° . *Benzalnitrocyanoacetylhydrazide*, obtained by shaking a mixt. of 1.1 g. BzH and 1.62 g. (g) in dil. HCl , chars without melting and in H_2O has strong acid properties. It is decompd. by warm H_2O , giving BzH and (f). With NaNO_2 , and decompn. of the resulting salt with dil. H_2SO_4 , (g) yields *nitrocyanoacetazide*, $\text{NCCH}(\text{NO}_2)\text{CON}_3\cdot\text{H}_2\text{O}$, yellow, hygroscopic crystals; it reacts in Et_2O with PhNH_2 , forming an *aniline salt* + H_2O , yellow crystals. Boiling alc. did not convert the azide into the expected urethan, but gave a dark brown, resinous mixt. from which nothing cryst. could be sepd. It is decompd. violently by boiling H_2O , giving N, CO_2 , HCN and some CO.

D. BREMER JONES.

Quinhydrones. W. SIEGMUND. Vienna. *J. prakt. Chem.* 92, 342-70(1915).—With reference to the compn. of quinhydrones most text books of org. chem. state that quinone adds 2 mols. of a monohydric, or 1 mol. of a dihydric phenol. Several exceptions to this rule have been recently observed. S. has increased these exceptions by the prepn. of a large number of mixed quinhydrones; he makes the following distinction between a true and a mixed quinhydrone: a true quinhydrone is one formed by the combination of a quinone with its corresponding quinol, and is an intermediate product of the reduction of a quinone to a quinol, or of the oxidation of the latter to the former; a mixed quinhydrone on the other hand is an addition product which can be formed by a quinone with a phenol which is not a dihydric phenol formed by reduction of the quinone. The following mixed quinhydrones were prepd. by warming their components in Et_2O , C_6H_6 , or petr. ether: *quinhydrone*, 2:3 [the mol. proportion of the compds. will be given in the order, quinone:phenol], from equimol. amts. of toluquinone + quinol, reddish brown leaves with metallic luster, m. $133-5^\circ$; *quinhydrone*, 1:1, from toluquinone + resorcinol; *quinhydrone*, 1:1, from toluquinone + pyrocatechol, m. $50-1^\circ$, very unstable; if the components are used in the ratio 1:2, only a dark oil is obtained; *quinhydrone*, 2:3, from thymoquinone + quinol, ruby needles, decomp. 137° ; yield, 85%; *quinhydrone*, 1:1, from thymoquinone + resorcinol, decomp. $43-5^\circ$; *quinhydrone*, 1:2, from *p*-xyloquinone + quinol, red needles, m. $153-6^\circ$; yield, quant.; *quinhydrone*, 1:2, from *p*-xyloquinone + pyrocatechol, red monoclinic crystals, m. 87° ; *quinhydrone*, 1:2, from *m*-xyloquinone + quinol, dark red leaves, m. $120-1^\circ$; *quinhydrone*, 2:3, from *m*-xyloquinone + pyrocatechol, long, red needles, m. $44-5^\circ$; *quinhydrone*, 1:1, from *o*-xyloquinone + quinol, red, lustrous needles, m. 118° ; *quinhydrone*, from *o*-xyloquinone + pyrocatechol, lustrous needles, m. $60-2^\circ$; *quinhydrone*, 1:1, from toluquinone + toluquinol, black needles, m. $96-7^\circ$; *quinhydrone*, 1:1, from thymoquinone + thymoquinol, m. 64° (cf. Kremers and Wakemann, *Pharm. Rev.* 26, 329). The following were prepd. from chlorinated quinones and quinol: *quinhydrone*, 2:3, from $\text{C}_6\text{H}_5\text{ClO}_2$, bronze crystals, m. $123-4^\circ$, identical with that obtained by Schmidlin, which he considered as a mixt. (cf. *C. A.* 5, 3252(1911)); *quinhydrone*, 1:1, from $m\text{-C}_6\text{H}_3\text{Cl}_2\text{O}_2$, reddish brown needles, m. 135° , identical with that obtained by Ling and Baker (cf. *J. Chem. Soc.* 63, 1314(1893)). The following were prepd. from phenolic acids: *quinhydrone*, 1:2, from $\text{C}_6\text{H}_4\text{O}_2$ + gentisinic acid, dark red needles, decomp. gradually without melting; *quinhydrone*, 1:2, from $\text{C}_6\text{H}_4\text{O}_2$ + β -resorcylic acid, red needles without a definite m. p.; *quinhydrone*, 1:2, from $\text{C}_6\text{H}_4\text{O}_2$ + 3,4-(OH)- $\text{C}_6\text{H}_2\text{CO}_2\text{H}$, dark red crystals, m. $179-80^\circ$; *quinhydrone*, 1:1, from $\text{C}_6\text{H}_4\text{O}_2$ + orcinol, dark red, lustrous prisms, decomp. $83-4^\circ$. Both gallic acid and its Et ester yield with $\text{C}_6\text{H}_4\text{O}_2$ ordinary quinhydrone, $\text{C}_6\text{H}_4\text{O}_2\cdot\text{C}_6\text{H}_3\text{O}_2$, due to the oxidation of the former by the latter.

D. BREMER JONES.

Action of the three isomeric aminophenols on α -naphthoquinone. E. GROSSMANN. Vienna. *J. prakt. Chem.* 92, 370-90(1915).—2 mols. of α -C₁₀H₇O₂ (a) react with 1 mol. H₂NC₆H₄OH in such a way that 1 mol. of quinone forms, with 1 mol. of the latter, a monoanilide, while the 2nd mol. of quinone serves as an oxidizing agent: 2 α -C₁₀H₇O₂ + H₂NC₆H₄OH = C₁₀H₇O₂.HNC₆H₄OH + α -C₁₀H₆(OH)₂. *p*-Hydroxy-2-anilido- α -naphthoquinone (b), 2, α -C₁₀H₆O₂.HNC₆H₄OH, prepd. by boiling 2 mols. (a) + *p*-H₂NC₆H₄OH for several hrs. in alc., dark red needles from alc., or PhNO₂, m. 225°, gives azure-blue solns. with alkalis, and cherry-red with concd. acids. On reduction with SO₂, SnCl₂, and TiCl₃ it forms leuco compds. which in the air are oxidized back to the original dye. The above reaction also proceeds in H₂O, but very slowly. 2.781 g. (a) in 1 l. H₂O + 1 g. *p*-H₂NC₆H₄OH in 200 cc. hot H₂O became turbid after standing for several days in a dark place, and in 2 months 1.39 g. of the anilide was obtained. By boiling for several hrs. (a) and *p*-anisidine in alc., to which a little AcOH had been added, *p*-methoxyanilido- α -naphthoquinone was obtained, needles from alc., m. 158°, gives bluish violet solns. with caustic alkalis in alc., and gives the same reactions toward reducing agents and concd. acids as (b). *p*-Ethoxy derivative, similarly prepd., m. 264°, red lanceolate crystals from alc. Yield, 90%. The diacetyl derivative, 2, α -C₁₀H₆O₂.NAcC₆H₄OAc, was obtained by allowing (b) to stand for several hrs. in an excess of Ac₂O to which a few cc. of H₂SO₄ had been added, red microscopic needles, m. 170°. *p*-Ethoxy-2-acetanilido derivative, prepd. by treating the corresponding EtO deriv. with Ac₂O + concd. H₂SO₄, m. 175°, dark powder. By adding BzCl, with cooling, to (b) in C₆H₅N, allowing the mixt. to stand 6-8 hrs., and adding a few cc. of concd. H₂SO₄, the benzoyl derivative, α ,2-C₁₀H₆O₂.NBzC₆H₄OH, was obtained, red, stout prisms, m. 210°. *m*-Hydroxy-2-anilido- α -naphthoquinone (c), prepd. like (b), violet, thread-like needles, m. 242°. The following derivs. of (c) were prepd.: *methoxy derivative*, from (c) and *m*-anisidine in alc., long red needles, m. 172°; *ethoxy derivative*, from (c) and *m*-phenetidine, red needles from alc., m. 195°; *benzoyl derivative*, from (c) and BzCl + C₆H₅N, dark red needles, m. 208°. *o*-Hydroxyanilido- α -naphthoquinone, obtained from (a) and *o*-H₂NC₆H₄OH, m. 205°, dark violet crystal complex. When its alc. soln. is poured into a large vol. of H₂O and the alc. expelled by evapn., it seps. as brown flakes which m. 175°. *Methoxy derivative*, from (a) and *o*-anisidine, dark red needles, m. 146°. *Ethoxy derivative*, from (a) and *o*-phenetidine, bright red needles, m. 152°.

D. BRASSE JONES.

Lichens and their characteristic constituents. XIII. O. HESS. Feuerbach. *J. prakt. Chem.* 92, 425-66(1915); cf. C. A. 5, 2074.—This paper is partly a repetition of H.'s work during previous yrs. on the chem. constituents of various lichens, including comparisons of his results with those of other observers. A previous examn. (extrn. with Et₂O, then with Me₂CO, and washing the resulting exts. with dil. KHCO₃) of *Aspicilia calcarea* (L.) Kbr. yielded aspicilin, a chromogen, erythrin and C₃₀O₄Ca (cf. *J. prakt. Chem.* 62, 468(1900)). This lichen was reexamd. with special reference to its erythritol content. Besides the above constituents, 0.23% erythritol was obtained, m. 120°. *Evernia prunastri* L. obtained from birches, lindens, and beeches yielded atranorin and evernic acid, while that obtained from oaks gave also some usnic acid (a). The following derivs. of evernic acid were prepd.: *potassium salt* + 2 H₂O, cryst. powder; *sodium salt*, silky needles; *barium salt*, prisms; *calcium salt*, short needles from alc.; *cupric salt*, green, microscopic needles; *lead salt*, fine needles; *silver salt*, microscopic prisms; *diacetyl derivative*, cryst. powder, m. 144°, gives in alc. a pale brown soln. with FeCl₃. By heating for 30 min. out of contact with the air, 10 g. evernic acid, or 12 g. of its K salt, with 8 g. KOH in 250 cc. H₂O, and acidifying with HCl, evernicinic acid was obtained; *acetyl derivative*, short prisms from C₆H₆, m. 111°; *potassium salt*, yellow needles very explosive; *nitro derivative*, small orange needles from H₂O, becomes red 175°.

m. 195° ; *dinitro derivative* + H_2O , golden needles, m. 87° , but does not lose H_2O up to 110° . Physodylic acid, m. 196° , which together with atranorin and evernunic acid was obtained from *Evernia furfuracea*, is identical with isidic acid found in the same lichen by Zopf (*Chem. Zentr.* 14, 105 (1903)). *Parmelia caperata* (L.), obtained from 3 different sources, yielded the following constituents: (1) from linden trees, capraric acid (b), 3.4%, caperatic acid (c), 2%, and a little of (a); (2) from rocks from a mountain, (b) 2.6%, (c) 2% and (a); (3) from a stone wall, (b) 6%, (c) 2% and (a). No trace was detected of caperin or caperidin, which are easily obtained from lichens grown on oak trees. An examn. of *Solorina crocea* (L.) Ach. showed the following constituents: solorinic acid (I), microscopic leaves from 2 C_6H_6 + alc., m. 202° , gives a violet soln. with caustic alkalis, and red with concd. H_2SO_4 ; *benzoyl derivative*, by heating 1 mol. of (I) with 4 Bz_2O for 4 hrs. at $90-100^{\circ}$, brown needles from AcOH, m. 153° , gives a dark, brownish red color with $FeCl_3$ in alc.; solorinol (II), by reducing (I) with Zn dust + AcOH, yellow cryst. powder, m. 162° ; on reduction with HI (I) is converted into *solorol* $C_{18}H_{14}O_7$, microscopic leaves, m. 216° ; with $FeCl_3$ in AcOH it gives a black soln. which on diln. becomes violet; heated with Ac_2O + $AcONa$ for 3 hrs. at $90-100^{\circ}$ it forms a *heptaacetyl derivative*, yellow-brown needles, m. 215° . Oxidation of this in glacial HOAc soln. with CrO_3 gives *hexacetylsolorone*, $C_{18}H_4(C_2H_5O)_6O_8$, yellowish brown needles, m. 197° . By boiling the latter with dil. KOH, and pptg. with HCl *solorone* (III), $C_{18}H_{18}O_8$, was obtained, scarlet needles, m. 280° . From the same lichen were furthermore isolated *hydrosolorinol* (IV), microcryst. powder, bluish violet in transmitted, and black in reflected light, gives a violet soln. with alkalis and most org. solvents. The following structures are suggested:

Soloric acid (d), $C_{18}H_{18}O_7$, needles, m. 205° ; in alc. it gives acid reaction, and with $CaCl_2$ a bluish red soln., which disappears on further addition of $CaCl_2$. On heating for 6 hrs. with MeOH it yields *methyl β -orcinolcarboxylate*, lustrous needles, m. 143° ; in alc. with a little $FeCl_3$ it gives a blood-red soln. (d) is a homolog of gyrophoric acid. Extn. of *Cladonia macilenta* (Ehrh.) Hoffm. yielded coccellic 0.4%, thamnolic 0.1%, and rhodocladonic acids. *Cladonia tenuis*, Floerke, yielded fumarprotocetraric acid (e) and δ -(a). Several different varieties of *Cladonia fimbriata* were examd. which showed distinct differences in the products obtained by extn. with Et_2O , $CHCl_3$ and Me_2CO . *Cladonia crispata* (Ach.) var. *gracilescens* (Rabenhorst) gave squamatic acid and cladonin, while *Cladonia condensata* (Flörke) Zopf. yielded (e), δ -(a) and cornicularin (f). From *Cladonia papillaria* (Ehrh.) var. *molariformis* (Hoffm.) were obtained atranorin, protolichesterinic acid and cladonin. Results obtained previously by H. and other investigators on the following lichens were confirmed: *Cornicularia aculeata* var. *stuppea* Fw., and *acanthella* Ach., and *Pertusaria ocellata variolosa* Fw. D. BRÉSE JONES.

α -Arylsulfonated nitriles. J. TROGER AND WUNDERLICH. Tech. Hochschule Braunschweig. *Arch. Pharm.* 253, 214-32 (1915).—By the action of arylsulfonates

on ClCH_2CN , derivs. of the general type, $\text{RSO}_2\text{CH}_2\text{CN}$, are formed (cf. *J. prakt. Chem.* [2] 71, 201-35), the H atoms of the CH_2 being replaceable by Na and alkyls (cf. *ibid* 72, 323), as also by aldehyde and oxime groups (cf. *ibid* 78, 123). Furthermore, the CN readily unites with H_2S and NH_4OH (cf. *ibid* 71, 201, 236). In the present investigation, an attempt has been made to prep. the hitherto unknown mono-Me derivs. of arylsulfoneacetonitriles and to study their activity. These new Me derivs. occupy a position midway between arylsulfoneacetonitriles and their dialkyl derivs. As the starting point for these expts. MeCHClCN (from MeCH(OH)CN and PCl_5), b. $123-4^\circ$ ($122-3^\circ$ according to Henry, *Belg. Acad. Bull.* 35, 360), was employed. On heating this compd. 8 hrs. with PhSO_2Na in a closed tube at $130-40^\circ$, α -benzenesulfonepropionitrile, $\text{PhSO}_2\text{CHMeCN}$, was obtained, needle-like prisms, m. 72° , very easily sol. in cold Et_2O , sol. in boiling H_2O , insol. in cold dil. NaOH . Attempts to prep. the compd. from $\alpha\text{-MeCCl}_2\text{CN}$ and PhSO_2Na were unsuccessful. Comparative studies on $\text{PhSO}_2\text{CH}_2\text{CN}$ and $\text{PhSO}_2\text{CHMeCN}$ with respect to their behavior toward 0.1 N NaOH at H_2O bath temp. revealed a max. hydrolytic limit of about 68%, at which point PhSO_2Me and PhSO_2Et begin to split off. Hydrolysis of the nitriles carries them beyond the corresponding amides. α -Benzenesulfonepropionamide, stout needles, m. 150° . α -Benzenesulfone- α -methylethenylamidoxime, $\text{PhSO}_2\text{CHMeC(NH)}_2\text{N}$:NOH, needle-like prisms, m. 147° , and the compound, $\text{C}_8\text{H}_{10}\text{O}_2\text{N}_2\text{S}$ (I or II), needles, m. 79° , are formed

on treating the nitrile with NH_4OH . α -Benzenesulfonethiopropionamide, $\text{C}_8\text{H}_9\text{ONS}_2$, by treating the nitrile in alc. NH_3 with H_2S , needle-like prisms, m. 159° , sol. in cold dil. NaOH without decompn. α -*p*-Toluenesulfonepropionitrile, from MeCHClCOCN and $p\text{-MeC}_6\text{H}_4\text{SO}_2\text{Na}$, bright yellow warty cryst. aggregates, m. 66° . Propionamide, leaflets, m. 166° . α -Methylethenylamidoxime, needle-like prisms, m. $140-1^\circ$. Thiopropionamide, yellowish, needle-like prisms, m. 149° . α -*p*-Chlorobenzenesulfonepropionitrile, $\text{C}_8\text{H}_8\text{O}_2\text{NSCl}$, rhombic leaves, m. $101-2^\circ$, practically insol. in H_2O , slightly sol. in cold dil. caustic alkalies. Propionamide, needle-like prisms, m. 190° . α -Methylethenylamidoxime, needles, m. 141° . Thiopropionamide, needle-like prisms, m. $140-1^\circ$, easily sol. in cold dil. NaOH without decompn. α -*p*-Bromobenzenesulfonepropionitrile, $\text{C}_8\text{H}_7\text{O}_2\text{NSBr}$, leaflets, m. 98° . Propionamide, leaflets, m. 196.5° . α -Methylethenylamidoxime, needle-like prisms, m. 145° . Thiopropionamide, yellowish, needle-like prisms, m. 176° . α -*p*-Iodobenzenesulfonepropionitrile, needle-like prisms, m. 115° . Propionamide, needle-like prisms, m. 210° . α -Methylethenylamidoxime, needles, m. 167° . Thiopropionamide, yellowish, needle-like prisms, m. 182° . W. O. E.

Arylamides of thiocynoacetic acid and arylthiohydantoins. H. BRCKURTS AND G. FRERICHS. *Tech. Hochschule Braunschweig. Arch. Pharm.* 253, 233-65 (1915).—On treating chloroacetaryl amides (from ClCH_2COCl and arylamines) with KCNS there is formed in certain instances an isothiocyanoacetyl compd., $\text{SCNCH}_2\text{CONHR}$, which very soon changes into the normal thiocyanoacetyl compd., $\text{NCSCH}_2\text{CONHR}$. In most cases the latter form is the one obtained, the former being well-nigh impossible of isolation in a pure state. On heating the normal thiocyanoacetyl compds. with H_2O or AcOH ,

they finally pass into arylthiohydantoins, $\text{HN} \cdot \text{CS} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{NR}$. In the case of thiocyanoacet-*o*-nitranilide, -*o*-anisidide and -*p*-phenetidide, this change takes place very readily, while with thiocyanoacet-*m*- and -*p*-nitranilide the transformation is accomplished with considerable difficulty, conditions obtaining apparently on account of the varying solubilities of these compds. Thiocyanoacetyl compds. only very slightly sol.

in H_2O and convertible only with difficulty into thiohydantoin are changed into the latter much more readily in $AcOH$. Arylthiohydantoin are both bases and acids, yielding with HCl cryst. salts (decompd. by H_2O), the same also with $NaOH$, although in the latter case simple addition takes place, yielding compds. possibly of the con-

stitution, $H_2N(ONa)C.S.CH_2.CO.NR$, which with alkyl halides form alkylated arylthiohydantoin. After protracted heating of arylthiohydantoin with HCl , preferably in a tube, substitution of the NH group for O takes place, thus yielding aryl derivs. of

mustard oil glycolides, $CO.S.CH_2.CO.NR$. In naming substituted thiohydantoin, the notation $HN:\overset{\gamma}{C}.S.\overset{\alpha}{C}CH_2.\overset{\beta}{CO}.NH$ is used. The following compds. were isolated and

characterized: *Chloroacet-m-toluide*, $MeC_6H_4.NHCOCH_2Cl$, prisms from C_6H_6 , m. $90-1^\circ$. *Isothiocyanacet-m-toluidide*, $SCNCH_2.CONHC_6H_7$, reddish white leaflets (not quite pure), m. 99° , is changed by protracted boiling in soln. or long standing in dry condition into the normal *thiocyanacet-m-toluidide*, $NCSCH_2.CONHC_6H_7$, microscopic, faintly yellow, hexagonal, oblique prisms from dil. alc., m. 136° . β -*m-Tolylthiohydantoin*, $C_{10}H_{10}ON_2S$, microscopic, quadratic leaves from dil. alc., m. 161° , easily sol. in alc., Et_2O and $AcOH$, less so in hot H_2O . Na compd., $C_{10}H_{10}ON_2S.NaOH.4H_2O$, leaflets. γ -*Ethyl- β -m-tolylthiohydantoin*, $C_{12}H_{14}ON_2S$, microscopic hexagonal prisms from dil. alc., m. $106-7^\circ$. *m-Tolylmustard oil glycolide*, $C_{10}H_9O_2NS$, needles from dil. alc., m. $90-1^\circ$. *Chloroacetpseudocumidide*, $Me_2C_6H_2NHCOCH_2Cl$, needles from alc., m. 159° . *Thiocyanacetpseudocumidide*, $C_{12}H_{14}ON_2S$, yellowish white, cubical crystals, m. 105° . β -*Pseudocumylthiohydantoin*, $C_{12}H_{14}ON_2S$, yellowish prisms from $AcOH$, m. 210° . The *hydrochloride*, $C_{12}H_{14}ON_2S.HCl$, yellowish prisms. $C_{12}H_{14}ON_2S.NaOH.5H_2O$, needles. γ -*Ethyl- β -pseudocumylthiohydantoin*, $C_{14}H_{18}ON_2S$, faintly yellow needles, m. 138° . The corresponding glycolide could not be prepd. *Chloroacet-p-chloroanilide*, $C_6H_4ONCl_2$, needles, from alc., m. 169° . *Isothiocyanacet-p-chloroanilide* was detected qual. in the reacting soln., but passed on crystn. from alc. into the normal *thiocyanacet-p-chloroanilide*, microscopic needles, m. 126° . β -*p-Chlorophenylthiohydantoin*, needles from alc., m. 213° . The *hydrochloride*, $C_6H_4ON_2ClS.HCl$, forms elongated leaflets, the *sodium hydroxide compound*, $C_6H_4ON_2ClS.NaOH.5H_2O$, brown acicular needles. γ -*Ethyl- β -p-chlorophenylthiohydantoin*, microscopic needles from dil. alc., m. $106-7^\circ$. *p-Chlorophenylmustard oil glycolide*, needles from alc., m. 145° . *Chloroacet-m-chloroanilide*, thick leaves from C_6H_6 , m. 101° , more readily sol. than the *p*-deriv. *Thiocyanacet-m-chloroanilide*, microscopic quadratic needles from alc., m. $165-6^\circ$. β -*m-Chlorophenylthiohydantoin*, needle-like aggregates from alc., m. $180-1^\circ$. The *hydrochloride* forms small yellowish oblong crystals, the *sodium hydroxide compound* $C_6H_4N_2ClS.NaOH+4.5H_2O$, reddish brown cryst. powder. The γ -ethyl- β -m-chlorophenylthiohydantoin could not be obtained in a pure state. *m-Chlorophenylmustard oil glycolide*, yellow needles, m. $116-7^\circ$. *Chloroacet-o-nitroanilide*, bright yellow needles from alc., m. 88° . *Thiocyanacet-o-nitroanilide*, cryst. powder, m. 154° . β -*o-Nitrophenylthiohydantoin*, plates, m. 172° . The *sodium hydroxide compound* has 3 mols. H_2O crystn. and forms yellow needles. The corresponding glycolide could not be prepd. γ -*Ethyl- β -o-nitrophenylthiohydantoin*, thick, light brown oil. *Chloroacet-m-nitroanilide*, yellowish leaves from alc., m. 114° , less sol. than the *o*-deriv. *Thiocyanacet-m-nitroanilide*, yellow quadratic needles from alc., m. 180° , less sol. than the *o*-deriv. β -*m-Nitrophenylthiohydantoin*, bright yellow tufts of microscopic needles from hot H_2O , m. 199° , less sol. than the *o*-deriv. The salt, $C_6H_4O_2N_2S.NaOH.2H_2O$, yellowish brown microscopic cryst. powder. γ -*Ethyl- β -m-nitrophenylthiohydantoin*, very like the *o*-deriv. *Chloroacet-p-nitroanilide*, yellowish leaves from alc., m. 182° . *Thiocyano-*

acet-p-nitroanilide, bright yellow needles from alc., m. 174°. *β-p-Nitrophenylthiohydantoin*, bright yellow oblong microscopic leaves, m. 245°. The salt, $C_8H_7O_2N_2S.NaOH.4H_2O$, yellow needles. *γ-Ethyl-β-p-nitrophenylthiohydantoin*, yellow needles, m. 129°. The other *p*-derivs. are less sol. than the corresponding *o*-derivs. *Chloroacetnitrotoluidide*, 3,4-(O_2N)($CICH_2CONH$) C_6H_4Me , from *p*- $MeC_6H_4NHCOCH_2Cl$ and HNO_3 (1.41), or from nitrotoluidine and $CICH_2COCl$, yellow needles from alc., m. 119°. *Thiocyanoacetnitrotoluidide* (1:4:3), yellowish needles, m. 133°. *β-Nitrotolylthiohydantoin* (1:4:3), bright yellow microscopic cryst. powder, m. 185°. *γ-Ethyl-β-nitrotolylthiohydantoin*, thick, light brown oil, easily sol. in alc., Et_2O , $AcOH$ and dil. acids. *Chloroacetnitrotoluidide* (1:4:2), 2,4- O_2N ($CICH_2CONH$) C_6H_4Me , bright yellow prisms from alc., m. 129°. *Thiocyanoacetnitrotoluidide* (1:4:2), microscopic, quadratic leaves from alc., m. 184°. *β-Nitrotolylthiohydantoin* (1:4:2), small, 4-sided prisms from alc., m. 206-7°. The salt, $C_{10}H_9O_2N_2S.NaOH.2H_2O$, yellow, microscopic needles. *γ-Ethyl-β-nitrotolylthiohydantoin* (1:4:2), yellow, hexagonal, microscopic leaflets from alc., m. 142°. *Chloroacetnitrotoluidide* (1:2:5), 5,2- O_2N ($CICH_2CONH$) C_6H_4Me , bright yellow needles from alc., m. 122°. *Thiocyanoacetnitrotoluidide* (1:2:5), 4-sided, microscopic prisms from alc., m. 158°. *β-Nitrotolylthiohydantoin* (1:2:5), yellow, microscopic, rhombic leaves from alc., m. 172°. The salt, $C_{10}H_9O_2N_2S.NaOH.3H_2O$, yellow, microscopic, tufted needles. *γ-Ethyl-β-nitrotolylthiohydantoin* (1:2:5), yellow, microscopic, rhombic leaves, m. 127-8°. *Chloroacet-p-anisidide*, acicular prisms from C_6H_6 , m. 122°. *Isothiocyanoacet-p-anisidide*, leaflets, not obtainable in a pure state. *Thiocyanoacet-p-anisidide*, yellowish prisms, m. 110-1°. *β-p-Methoxyphenylthiohydantoin*, leaves soon changing to yellowish brown, m. 184°. The hydrochloride, $C_{10}H_{10}O_2N_2S.HCl$, yellowish leaflets. The sodium hydroxide salt has 4 mols. H_2O of crystn. *γ-Ethyl-β-p-methoxyphenylthiohydantoin*, prisms from dil. alc., m. 84-5°. *p-Methoxyphenylmustard oil glycolide*, needles from alc., m. 166°. *Chloroacet-o-anisidide*, fine needles from alc. or stout, rhombic tablets from the oily crude product on addition of alc. and concd. HCl in the cold, m. 51°. *Thiocyanoacet-o-anisidide*, prisms from alc., m. 72°. *β-o-Methoxyphenylthiohydantoin*, yellowish, 4-sided prisms from alc., m. 149°, crystals from $AcOH$ with 1 mol. $AcOH$, m. 110-1°. The hydrochloride, yellow prisms. The sodium hydroxide compound, needles. *γ-Ethyl-β-o-methylphenylthiohydantoin*, $C_{12}H_{14}O_2N_2S$, yellow, rhombic tablets from alc., m. 126-7°. *o-Methoxyphenylmustard oil glycolide*, yellow, rhombic tablets, m. 113-4°. *Thiocyanoacet-p-phenetide*, microscopic, 4-sided prisms from C_6H_6 , m. 130-1°. *β-p-Ethoxyphenylthiohydantoin* (d. Grothe, *ibid* 238, 612), needles from alc., m. 167°. The hydrochloride, yellowish needles. The sodium hydroxide compound, $C_{11}H_{12}O_2N_2S.NaOH.4H_2O$, yellowish white prisms. *γ-Ethyl-β-p-ethoxyphenylthiohydantoin*, $C_{13}H_{16}O_2N_2S$, yellowish brown, rhombic plates from alc., m. 94-5°. *p-Ethoxyphenylmustard oil glycolide*, yellowish needles from alc., m. 155-6°. W. O. E.

Nitro derivatives of alkylbenzidines. G. VAN ROMBURGH. *Proc. Akad. Wetenschappen* 18, 757-60(1915).—P. van Romburgh (*Rec. trav. chim.* 5, 240(1886)) showed that in the nitration of $PhNMe_2$ there are formed as by-products derivs. of tetranitrobenzidine (a), without detg. the positions of the NO_2 groups. G. van R. has studied the structure of these compds. and has prepd. a number of NO_2 derivs. of alkylbenzidines. He prepd. (a) in 35% yield by adding 30 g. $PhNMe_2$ to 900 cc. HNO_3 (d. 1.11) at 5° and allowing to stand overnight. Recrystd. from $PhOH$ it decomps. 272°. *Tetra-nitrodiphenyl diethyl ether* (b), long, transparent needles, m. 256-7°, was prepd. from fuming HNO_3 and [*p*- $EtOC_6H_4$] $_2$. Two g. (b) with 1 g. Me_2NH in 25 cc. $EtOH$ in a sealed tube at 120° gave [$(NO_2)_2C_6H_4OH$] $_2$. This, boiled with concd. HNO_3 , yielded picric acid, showing that the NO_2 groups in (b) must be in the positions 3,5,3',5'. No [$(NO_2)_2C_6H_4NMe_2$] $_2$ was formed. By treating (b) with $MeNH_2$, R. obtained 3,5,3',5'.

tetraamino dimethylbensidine, dark red crystals from PhOH, decomp. 282° . Similar alkyl derivs. were formed from (b) and EtNH_2 , PrNH_2 , iso-PrNH_2 , iso-BuNH_2 and $\text{C}_4\text{H}_9\text{NH}_2$. These will be described in a paper soon to be published in *Rec. trav. chim.* By reduction of the NO_2 compds. with Sn and HCl were prepd. *tetraaminotetramethylbensidine hydrochloride*, colorless needles, with 4 HCl and 2 H_2O , decomp. 251° ; *tetraaminodimethylbensidine hydrochloride*, colorless needles with 4 HCl and 1 H_2O . By diazotizing these NH_2 compds. and condensing with naphthylamino- and naphthol-sulfonic acids were obtained red to bluish violet dyes, some of which dye cotton without a mordant.

E. H.

Bixin. I. J. RINKES. *Chem. Weekblad* 12, 996-1000(1915).—For the prepn. of methylbixin annatto paste was used, from which the resin was previously extd. with acetone. Mono-K bixinate was then obtained from the resin-free paste. This compd. was transformed into methylbixin with the help of Me_2SO_4 , recrystd. from AcOEt and twice from acetone, dried at 100° *in vacuo* and kept over P_2O_5 . Calcd. C 77.09%; found C 77.15%, H 7.90%. Methylbixin in 15 parts of dry CHCl_3 was ozonized in 10 g. portions, until the deep red soln. showed a slightly yellow tinge. The CHCl_3 was removed *in vacuo* below 22° , the syrupy ozonide allowed to stand for 12 hrs. and heated at 90° for 2 hrs. The aq. soln. of the aldehydes was distd. off *in vacuo* under cooling with CO_2 . The distillate reduces Fehling's soln. A portion of it was treated with PhNHNH_2 in 50% AcOH , and allowed to stand for a day, after which a deposit of slightly yellow needles occurred. After recrystn. from alc. it m. 148° , which is the m. p. of methylloxalbisphenylhydrazone. The remainder was treated with $p\text{-O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$ in 50% AcOH ; the largest part of the resulting phenylhydrazone was insol. in alc. The total quantity was boiled with alc. and the insol. part recrystd. from PhNO_2 in which it is readily sol. when heated, and from which it crystallizes in small needles, decomp. about 300° ; the temp. of decompn. of methylglyoxalbis- p -nitrophenylhydrazone being $302\text{--}304^{\circ}$. With alc. and NaOH a deep blue color was formed. From the mother liquid of the nitrophenylhydrazones a nicely crystd. compd. was deposited within a few days. This after 2 recrystns. from alc., m. 206° ; it produced a red color with alc. NaOH. This compd. appeared to be acetyl- p -nitrophenylhydrazine. Another quantity of the aldehyde mixt. made from methylbixin as previously described was treated with semicarbazide and allowed to stand overnight. The resulting cryst. mass only slightly dissolved in the usual solvents, and when decolorized with animal charcoal, m. $255\text{--}256^{\circ}$, the m. p. of methylglyoxalbissemicarbazone. Methylglyoxalbissemicarbazone, obtained through the ozonization of mesitylene m. 256° . From all these properties it appears that one of the decompn. products of methylbixin ozonide is methylglyoxal.

J. T. FLOHL.

Biochemical synthesis by the aid of α -glucosidase of the α -monoglucoside of isopropylene glycol. E. BOURQUELOT AND A. AUBRY. *J. pharm. chim.* 12, 283-9 (1915); *Compt. rend.* 161, 364-7(1915); cf. *C. A.* 9, 1309.—In a preliminary expt., 7 mixts., each containing 1 g. dextrose in 70 cc. H_2O , 10 cc. of yeast ext. (10 g. air-dry bottom yeast extd. for 24 hrs. with 100 cc. H_2O , filtered), 10 drops PhMe , and severally 10, 20, 30, 40, 50, 60 and 70 g. of $\text{MeCH(OH)CH}_2\text{OH}$ and sufficient H_2O to make 100 cc., were left at ordinary temp. for 95 days. The march of optical rotation showed growth of the synthetic action up to 40 g. per 100 cc.; but with 50 g., destruction of the enzyme was almost complete. This places the toxicity of this glycol between that of EtOH (36-40 g.) and $\text{CH}_2\text{(OH)CH}_2\text{OH}$ (70-75 g. per 100 cc.). To prep. the new glucoside, a mixt. of 93 g. dextrose, 150 cc. H_2O , 248 g. $\text{MeCH(OH)CH}_2\text{OH}$ (37 g. per 100 cc.), 195 cc. ext. of air-dried bottom yeast, and H_2O to make 665 cc., is kept at ordinary temp. for 127 days. On the 62nd day 45 cc. more of yeast ext. was added to replenish α -glucosidase eventually destroyed. The optical rotation increased by

8° 18'. Now boil the mixt., cool, add 3 vols. 95% EtOH to ppt. colloids, filter, recover the EtOH by distn., then the unchanged glycol by distn. at 115–120° in a partial vacuum, dissolve the nearly black ext. in 1000 cc. H₂O, destroy excess of dextrose, by the aid of fresh yeast, filter, defecate with Pb subacetate, remove Pb by H₂S and again distil under reduced pressure. The red-brown ext. (66 g.) was treated with boiling AcOEt which removed the rest of the glycol and small amts. of the glucoside. No crystals could be obtained. Again evapd. to firm consistency *in vacuo*, the residue was extd. with 14 times 500 cc. AcOEt. The solvents evapd. left only 8 g. It was purified by treatment with 50 cc. of abs. EtOH and 30 cc. Et₂O, and the degree of glucosidification in the evapd. ext. was detd. by hydrolysis with H₂SO₄ in H₂O soln. The amt. of dextrose found indicated a slightly impure *isopropylene glycol mono- α -D-glucoside*. By observing the march of optical rotation in 2 specimens when hydrolyzed by the α -glucosidase of yeast ext., two monoglucosides, corresponding to the 2 alc. functions of the glycol, appear to be formed; in one $[\alpha]_D > 143.5^\circ$, in the other $+134.7^\circ$. S. WALDBOTT.

Addendum (to the action of aldehydes on hydramines of the pyrrolidine and piperidine series). K. HESS. Univ. Freiburg i/B. *Ber.* 48, 2067–8 (1915); cf. *C. A.* 10, 467.—In the exptl. part of the former paper it was neglected to report how the HCHO formed when 1-(α -N-methylpiperidyl)ethan-2-al is warmed some time with alkali was identified. The soln. acidified with AcOH and treated with the calcd. amt. of PhNHNH₂, deposits after some time in ice leaflets, m. sharply 156.5°, of the hydrazone C₇H₁₂N₂. CHAS. A. ROUILLER.

Yohimbine. III. Composition of yohimbine and its relationships to yohimboic acid. Mesoyohimbine, a new yohimbe alkaloid. L. SPIEGEL. Univ. Berlin *Ber.* 48, 2077–83 (1915); cf. *Ibid* 38, 2825 (1905); Fournéau and Page, *C. A.* 8, 2704.—S. believes he has obtained definite proof that yohimbine (a) has the compn. C₂₁H₃₃O₂N₂, and, therefore, differs by 2 C atoms from yohimboic acid (b), C₂₀H₂₈O₄N₂; this proof consists in the discovery of a compd. intermediate between (a) and (b), *vis.*, *mesoyohimbine*, C₂₁H₃₃O₂N₂ (c). The (a) was obtained from the com. hydrochloride (Güstrow) by pptn. with NH₄OH and recrystd. from 50% alc. until it m. 234.5° constantly and no (c) could be detected in the mother liquors; analyses then showed 71.62–71.94% C, 7.42–7.73% H and 7.74% N. If a sample of (a) containing some (c) is crystd. from 50% alc. and the mother liquors are concd. on the H₂O bath to incipient crystn., the crystals obtained on cooling are less well defined and melt lower, and by repeated recrystn. from the least possible amt. of 50% alc. the (a) can be completely removed and (c) is finally obtained in spherical aggregates sepg. from C₆H₆ or abs. alc. in needles m. 247°, with 70.98–71.09% C, 7.48–7.69% H, 7.95% N, 8.41% MeO. Perfectly pure (a) can be partially converted into (c) by heating 1 g. of it 5 hrs. with 20 cc. alc. and 0.5 mol. KOH; all attempts, however, to prep. (c) from (b) or (a) from (c) by esterification have thus far failed. (c) in general behaves like (a) but is more difficultly sol. in abs. alc. and C₆H₆ and more easily sol. in aq. alc., dissolves almost without color in concd. H₂SO₄ and remains so for 24 hrs.; addition of a crystal of bichromate to the soln. produces a blue-green color. (c) is *d*-rotatory apparently to about the same degree as (a). Its hydrochloride seps. from H₂O in needles. Physiologically, (c) has an action similar to but weaker than that of (a). The presumed identity of yohimbine and quebrachine. *Ibid* 2084–7.—S. has found that Merck's "quebrachine" consists essentially of (a) mixed with a little (c). The description given by Fournéau and Page of their (a) and "quebrachine" differs in some respects, however, from that of the product obtained by Hesse from *Quebracho blanco* (*Ann.* 211, 265 (1882)). H.'s original prepn. was no longer available for direct comparison and S. attempted to prep. the substance from the bark according to H.'s directions but was unable to obtain either (a) or any substance which could with certainty be said to correspond to

H.'s compd.; after repeated fractionation by pptn. and crystn. were obtained only a few crystals, apparently not quite pure, m. 201° , sol. almost without color in concd. H_2SO_4 , and giving with bichromate a transient blue color, while in alc. or dil. HCl , FeCl_3 gives a yellow color. S. concludes that in many barks of *Quebracho blanco* are present alkaloids of the (a) group and probably (a) itself (cf. also Ewins, *C. A.* 9, 606; Barger and Field, *C. A.* 9, 2888), but that it cannot be definitely stated that H.'s original product was identical with (a).
CHAS. A. ROULLER.

β -Binaphthol and β -hydroxy- α,β -naphthyl ether. O. HINSBERG. Freiburg i. B. *Ber.* 48, 2092-5(1915); cf. *C. A.* 9, 2064.—The compd. $\text{C}_{20}\text{H}_{14}\text{O}$, m. 197° , obtained as chief product of the treatment of dehydro- β naphthol sulfone with Zn, AcOH and HCl and supposed to be a binaphthol, has now been found to be β -hydroxy- α,β -naphthyl ether, $\text{HO}(\text{C}_{10}\text{H}_7\text{O})\text{C}_{10}\text{H}_7$ (a). In an attempt to synthesize it, α,β - $\text{C}_{10}\text{H}_7\text{Br}(\text{OH})$ was heated 15 min. at 230° with 2.5 parts Cu powder but gave β,β' -dinaphthol, m. 216° , also obtained as the chief product when 2 g. $\text{C}_{10}\text{H}_7\text{Br}(\text{OH})$ and 1.2 g. β -naphthol are warmed with 0.4 g. Na in dil. MeOH; if no β -naphthol is used the reaction takes an entirely different course, a light yellow product insol. in alkalies being formed. (a) does not react with ketone reagents; the alk. soln. with $\text{K}_3\text{Fe}(\text{CN})_6$ forms a yellow ppt. Analysis of the acetate previously described which m. 115° gave varying results, all of which, however, were low for a monoacetate; the compd. seems to retain varying amts. of solvent which are lost only slowly and incompletely on drying. *m*-Nitrobenzenesulfonate, needles from MeOH- CHCl_3 , m. 139° . *p*-Nitrobenzoate, light yellow needles from AcOH, m. 154° .
CHAS. A. ROULLER.

8-Hydroxyquinolinecarboxylic acids and their derivatives. Dihydroxyanthraquinone-3,7-di quinoline. ST. VON NIEMENTOWSKI AND ED. SUCHARDA. Lwów. *Ber.* 49, 12-24(1916).—8-Hydroxyquinoline-5-carboxylic acid (a) is obtained in 30 g. yield from 100 g. 4,3-HO(H_2N) $\text{C}_6\text{H}_3\text{CO}_2\text{Me}$ ("orthoform new"), 150 g. As_2O_3 , 300 g. glycerol and 300 g. concd. H_2SO_4 heated 3 hrs. at 140 – 50° . The cooled mass is dild. with an equal vol. of H_2O , the resulting sulfate filtered after 21 hrs., recrystd. 3 times from H_2O containing H_2SO_4 , treated in acid soln. with NH_3 until still just faintly acid and the free (a) pptd. with NaOAc; it is then treated with hot 10% NH_4OH until a satd. soln. is formed and the resulting cryst. NH_4 salt decompd. in hot H_2O with AcOH. It seps. from AcOH in yellowish microcrystals, m. 301° , decomp. a few degrees higher into CO_2 and 8-hydroxyquinoline (b); the same decompn. occurs on long boiling of the aq. neutral, alk. or acid soln.; the aq. soln. gives a green color with FeCl_3 but no color with FeSO_4 ; boiling dil. HNO_3 oxidizes it and concd. acid nitrates it at room temp. It is identical with the acid, m. 280° , obtained by Lippmann and Fleissner from (b) and CCl_4 (*Ber.* 19, 2467(1886)). Hydrochloride, needles with 1 H_2O from 20% HCl , m. 260° (foaming), partially hydrolyzes in H_2O . Sulfate, $(\text{C}_{10}\text{H}_7\text{O}_2\text{N})_2\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, yellow microcrystals from 2.5% H_2SO_4 , m. 240° . Barium salt, needles with 2 H_2O ; excess of (a) boiled with an aq. suspension of $\text{Ba}(\text{OH})_2$ dissolves with yellow color in the form of the acid salt. Ammonium salt, loses NH_3 in the air. Ethyl ester, from 10 g. (a) in 150 g. concd. H_2SO_4 heated 4 hrs. on the H_2O bath with 30 cc. alc., needles from C_6H_6 , m. 125° . Heated 2 hrs. at 150° with 16 parts of concd. H_2SO_4 (a) yields a hydroxyquinolinesulfonic acid, needles from H_2O , m. 295 – 300° , probably identical with Claus' 8,5- $\text{C}_8\text{H}_4\text{N}(\text{OH})\text{SO}_3\text{H}$ (*J. prakt. Chem.* 55, 457(1897)); the mother liquors after some weeks deposit a substance m. 272 – 8° , possibly Claus and Posselt's *o*-hydroxyquinoline-disulfonic acid (*J. prakt. Chem.* 41, 32(1890)). With KMnO_4 in boiling dil. alk. soln. (a) gives quinolinic acid. 8-Hydroxyquinoline-6-carboxylic acid (c) is obtained in 73 g. yield from 100 g. 3,4-HO(H_2N) $\text{C}_6\text{H}_3\text{CO}_2\text{Me}$ ("orthoform"), 150 g. As_2O_3 , 300 g. glycerol and 300 g. H_2SO_4 heated 3 hrs. at 155 – 60° ; after dildn. with an equal vol. of H_2O and standing 12 hrs., the filtered soln. is pptd. with NaOH in fractions, the dried ppts. taken up

in the least possible amt. of dil. HCl and pptd. as the HCl salt with concd. HCl and the free (c) obtained from the salt by treatment in hot H₂O with NH₄OH and NaOAc and crystn. from AcOH; it m. 284°, dissolves in alkalis and mineral acids, gives a green color with FeCl₃ in H₂O but no color with FeSO₄, oxidized by boiling dil. HNO₃, converted into the mono- and di-NO₂ derivs. by concd. HNO₃ at room temp., can be sublimed or distd. over lime without change, oxidized by KMnO₄ to quinolinic acid. *Hydrochloride*, yellow-bronze crystals with metallic luster, m. 312°, sol. in H₂O without being hydrolyzed. *Sulfate*, yellow microcrystals with 1 H₂O, m. 307°. *Phosphate*, (C₁₀H₇O₂N)₃·H₃PO₄·0.5H₂O, gray-yellow microcryst. ppt., m. 285°. *Ammonium salt*, slowly decomps. at room temp., instantly at 120°. *Acid silver salt*, from a boiling aq. soln. of (c) and AgNO₃, light gray ppt.; *neutral salt*, from a boiling soln. of the NH₄ salt and AgNO₃, microcryst. gray-yellow ppt. *Barium salt*, gray cryst. ppt. *Ethyl ester*, needles from C₆H₆, m. 147°, sublimes in leaflets. When 50 g. (c) is heated 4 hrs. at 240° with 350 g. H₂SO₄ and 70 g. P₂O₅, poured into 2.5 l. H₂O, cooled, treated with NH₄OH until still just acid, filtered after 3 hrs., boiled with dil. HCl, then with H₂O, extd. with 8 l. of PhMe-xylene, the resulting crystals (3 g.) treated in 100 cc. of 25% H₂SO₄ with 50 cc. concd. HCl and the salt segg. on cooling is decompd. with boiling NH₄OH (the soln. being kept faintly acid), there is obtained 1.8 g. of what is doubtless

2,6-dihydroxyanthraquinone-3,7-diquinoline,

golden yellow

needles from AcOH, m. 386° (carbonization); 1 l. hot AcOH dissolves 0.55 g. and about 0.35 g. seps. on cooling; it is sol. in concd. H₂SO₄ with yellow color, difficultly sol. in dil. acids, the free base segg. on cooling; from 60% H₂SO₄ seps. the sulfate which at once hydrolyzes in H₂O; in alkalis and NH₃ the compd. is difficultly sol., the suspensions, however, changing to red, probably owing to salt formation. Treated in KOH with hyposulfite, it is reduced to the hydroxyanthranol, sol. with violet color and oxidized back to the quinone by atm. O; the red-violet vat dyes cotton a permanent orange; alc.-aq. suspensions of the compd. dye cotton mordanted with Al₂O₃ or Fe salts yellow.

CHAS. A. ROUILLER

Derivatives of methylenecamphor. HANS RUPE AND MARTIN ISELIN. *Ber.* 49, 25-50(1916).—Continuation of the study of the influence of constitution on rotatory power (*C. A.* 9, 2876). The alkyl derivs. of methylenecamphor (a) obtained by the action of alkyl halides on Na camphor, bromination of the product and elimination of HBr (Haller and March, *Compt. rend.* 142, 318(1906)) do not seem to be optically pure in all cases. A general method for the prepn. of aliphatic or aromatic derivs. of (a) consists in treating its chloride (b) with Grignard reagents. With aliphatic Mg compds. although the yields are quite good, the product is usually contaminated with unchanged chloride which, however, can easily be removed as hydroxymethylenecamphor (c) by boiling with alc. KOH; the yields increase with increasing mol. wt. With aromatic Mg compds., the products are usually obtained directly free from halogen. Refractometrically, the derivs. of (b) described in this paper show an av. sp. exaltation ΣE_D 0.76 and $\Sigma E_{D-\alpha}$ 24.5% which may be considered as characteristic of a disturbed ("gestörte") conjugation; the disturbance suffered by the conjugation of the 2 double bonds of the keto and methylene groups is produced by the camphor ring itself. (b), b.p. 113°, is obtained in 95% yield by slowly adding 1 mol. finely powdered (c) to 2 mol.

SOCl_2 , letting stand several hrs. and warming 0.5 hr. at 40° ; it soon becomes yellow, has a characteristic odor like that of *Asarum europaeum*, solidifies in ice to a camphor-like mass, $[\alpha]_D^{20}$ 180.28° (C_6H_6); its formation is an endothermic process; the calorific effect of the formation of 5.22 g. (b) from 5.0 g. (c) and 6.62 g. SOCl_2 is -118 cal. Methylmethylenecamphor (d), $\text{CO.C}_8\text{H}_{14}.\text{C}:\text{CHMe}$, is prepd. by passing into 32.4

g. Mg in 550 cc. Et_2O in ice-salt, with const. stirring, a current of dry MeBr for 16 hrs. at such a rate that the MeBr at once reacts and the Et_2O never boils vigorously; after standing overnight the mixt. is slowly dropped, with const. stirring, into 200 g. (b) in 200 g. Et_2O , stirred 1 hr. longer, allowed to stand several hrs., decompd. in the usual way with cold NH_4Cl , extd. with Et_2O , fractionated, the fraction b_{11} $109-10^\circ$ (125 g.) boiled 4 hrs. with 1 vol. EtOH and 1 vol. of 33% KOH in MeOH, poured into much H_2O , extd. with Et_2O and fractionated. It b_{12} $109-10^\circ$, solidifies to radiating crystals, m. $28-9^\circ$, has a camphor-like aromatic odor, $[\alpha]_{20}$ 136.37° , 178.58° , 219.31° , 308.49° , for C, D, E and F, resp., in C_6H_6 (Minguin and Haller, *Compt. rend.* 138, 578 (1904) give 113° for D in alc.). In the distn. of the crude product there remains a tarry residue, the greater part of which b_{11} $240-55^\circ$ and quickly solidifies; crystn. from alc. and from C_6H_6 -gasoline shows that it consists of a mixt. of 2 compds.: yellowish pointed needles, m. $280-1^\circ$, and white microcryst. powder, m. $183-4^\circ$. When (d) is heated *in vacuo* over Na, camphor sublimes and the residue, extd. with Et_2O , shaken with dil. H_2SO_4 , dried and distd., gives a yellow oil, b_{11} $238-50^\circ$, solidifies and seps. from alc. in felted needles, m. $169-70^\circ$. Ethylmethylenecamphor (e) (Haller, *Compt. rend.* 142, 1309 (1906)), obtained in 70.4 g. yield (crude product after 1 distn., with 1.88% Cl) from 15.1 g. Mg, 380 cc. Et_2O , 68 g. EtBr and 99.2 g. (b), b_{12} $121-2^\circ$, d_4^{20} 0.9448, $[\alpha]_{20}$ 131.39° , 172.95° , 212.96° , 301.48° without solvent, 130.72° , 171.26° , 210.60° , 296.48° in alc., 119.07° , 157.44° , 195.25° , 276.96° in C_6H_6 , for C, D, E and F, n 1.48707, 1.49042, 1.49902, 1.50624 and M 58.50, 58.84, 59.72, 60.45 for α , D, β and γ . The purification with alc. KOH involved a loss of almost 50%; the aq.-alc. residues from 61 g. crude product on neutralization, concn. and acidification yielded 5.2 g. (c). Attempts to purify 40 g. of the crude product by treating with 40 g. Al-Hg and, in the course of 4 hrs., 20 cc. H_2O , gave 3 g. of (e) still containing some Cl and a resin partially b_{12} $239-41^\circ$ as a viscous oil depositing in 6 months a few crystals sepg. After repeated crystns. as felted needles, m. $169-70^\circ$, having apparently the compn. $\text{C}_{20}\text{H}_{30}\text{O}$, also obtained in very small amt. when twice the calcd. amt. of Mg is used in the synthesis of (e) and when (c) is heated with Na (see above). Propylmethylenecamphor, obtained in 68.1 g. yield from 16.2 g. Mg, 300 cc. Et_2O , 77 g. PrBr and 100 g. (b), and freed from the last trace of Cl, after treatment with alc. KOH, by distn. over Na, b_{12} $131-2^\circ$, d_4^{20} 0.9380, $[\alpha]_{20}$ 124.51° , 161.95° , 200.07° , 285.83° without solvent, 112.57° , 149.32° , 185.40° , 264.75° in C_6H_6 , for C, D, E and F, n 1.48621, 1.48946, 1.49778, 1.50490 and M 63.13, 63.49, 64.41, 65.17 for α , D, β and γ . Isobutylmethylenecamphor (f), in 65 g. yield from 14.0 g. Mg, 250 cc. Et_2O , 68.4 g. iso-BuBr and 80 g. (b), b_{12} $136-8^\circ$, d_4^{20} 0.9275, $[\alpha]_{20}$ 118.67° , 156.69° , 193.40° , 275.90° without solvent, 109.55° , 145.04° , 179.05° , 254.12° in C_6H_6 for C, D, E and F, n 1.48419, 1.48772, 1.49594, 1.50295 and M 67.95, 68.37, 69.35, 70.18 for α , D, β and γ ; 3.5 portions of 10 g., each treated in 60 g. CCl_4 with O_3 for 10 hrs., then heated 2 hrs. with H_2O at 100° , gave 5.5 g. camphorquinone, camphoric acid and isovaleric acid. From 18.2 g. allyl bromide (b_{12} 71°), obtained in 59% yield from the alc. and HBr), 3 g. Mg, 100 cc. Et_2O and 20 g. (b) is obtained an oil which de-comps. around 130° under 14 mm., yielding a yellow acid oil rich in Cl, evolving heat when brought in contact with alc. KOH; after boiling several hrs., pouring into H_2O and extg. with Et_2O is obtained a hydrocarbon $\text{C}_{10}\text{H}_{14}$ or $\text{C}_{10}\text{H}_{12}$, mobile oil with a borneol odor, b_{12} $107-8^\circ$. Phenylmethylenecamphor, obtained in 25 g. yield from 10.1 g.

Mg, 65.4 g. PhBr, 200 cc. Et₂O and 66.1 g. (b), *b*₁₂ 195-7°, crystals from alc. or petr. ether, *m.* 98.5°, [α]_D²⁰ 322.48°, 426.55°, 530.40°, 741.87° for C, D, E and F in C₆H₆ (Haller, *Compt. rend.* 136, 578, 751 (1903), gives 425.1° for D in PhMe). *Benzylmethylenecamphor* (g), in 205 g. yield from 44.2 g. Mg, 235.2 g. PhCH₂Br, 1 l. Et₂O and 300 g. (b), *b*₀₋₂₁ 124-6°, *d*₄²⁰ 1.0250, [α]_D²⁰ 97.87°, 129.00°, 159.26°, 226.50° without solvent, 87.78°, 115.72°, 143.39°, 203.31° in C₆H₆, 98.29°, 129.83°, 160.40°, 227.02° in alc. for C, D, E and F, *n* 1.54472, 1.54948, 1.56157 and *M* 78.37, 78.94, 80.37 for α , D and β . In its prepn. is obtained 135 g. of a lower boiling fraction containing Cl; 100 g. of this boiled with alc. KOH yields 26 g. of an oil which, after distn. over Na, *b*₁₄ 143-4.5° and has the compn. C₁₅H₁₄O; the alk. residues yield an amt. of (c) corresponding to 40.5 g. unchanged (b). Ozonization of 33 g. (g) yields 7 g. camphorquinone, 7 g. unchanged (g), 0.6 g. BzOH, 4 g. camphoric acid and 0.7 g. PhCH₂CO₂H; 8 g. of the latter ozonized 14 hrs. in CCl₄-CHCl₃ gave much HCO₂H and only 1 g. unchanged acid, which explains why so little is obtained in the ozonization of (g). *Phenethylmethylenecamphor*, in 58.2 g. yield from 10.1 g. Mg, 77.0 g. PhCH₂CH₂Br, 300 cc. Et₂O and 66 g. (b), *b*₁₂₋₁₃ 208-10°, *b*₀₋₂₁ 152-4°, *d*₄²⁰ 1.0094, [α]_D²⁰ 96.61°, 127.99°, 157.97°, 225.20° without solvent, 89.32°, 117.70°, 145.52°, 206.96° in C₆H₆ for C, D, E and F, *n* 1.53575, 1.54035, 1.55149 and *M* 82.81, 83.41, 84.83 for α , D and β . *Phenylpropylmethylenecamphor*, in 39 g. yield from 7.6 g. Mg, 62.2 g. PhCH₂CH₂CH₂Br, 250 cc. Et₂O and 49.6 g. (b), *b*₁₅ 221-3°, *d*₄²⁰ 0.9990, [α]_D²⁰ 87.94°, 113.33°, 139.92°, 198.76° without solvent, 82.01°, 108.03°, 133.26°, 188.59° in C₆H₆ for C, D, E and F, *n* 1.53300, 1.53735, 1.54824, 1.55814 and *M* 87.68, 88.27, 89.76, 91.10 for α , D, β and γ . *Cyclohexylmethylenecamphor*, in 50 g. yield from 80.0 g. C₆H₁₁Br, 14.0 g. Mg, 250 cc. Et₂O and 80.0 g. (b), *b*₁₁ 171-3°, flat prisms from gasoline, *m.* 46-8° (Haller, *Compt. rend.* 142, 317 (1906), gives 49°), [α]_D²⁰ 97.46°, 128.13°, 157.36°, 216.08° in C₆H₆ for C, D, E and F. α -*Naphthylmethylenecamphor*, *b*₁₂₋₁₃ 253-4°, long prisms from alc., *m.* 98-9.5°, [α]_D²⁰ 263.17°, 353.62°, 443.94°, 634.54° in C₆H₆ for C, D, E and F. From 12 g. *p*-IC₆H₄Ph, 50 cc. C₆H₆, 30 cc. Et₂O, 1.8 g. Mg activated with I and 6.5 g. (b) are obtained much Ph₂(*p*-PhC₆H₄)₂, the mixt. of compds. *m.* 183-4° and 280-1° (see under (d) above), and a small amt. of a substance, possibly the diphenylmethylenecamphor sought, sepg. from alc. in fatty scales, *m.* 138-43°. When Mg in Et₂O is treated with (b) the thick red ppt. formed quickly protects the Mg from further attack by the (b), in spite of vigorous stirring; if C₆H₆ is previously added to the Et₂O, energetic reaction takes place but it is difficult to isolate a pure substance from the tarry product, only a small amt. of a compd. C₁₀H₁₄O crystg. from alc. and *m.* 254-6° being obtained. When, however, 12.2 g. Mg strongly activated with I in 150 cc. Et₂O is slowly treated with 100 g. (b) in 150 cc. C₆H₆ and gently boiled 20 hrs. with vigorous stirring, the mixt. of compds. *m.* 183-4° and 280-1° (see above) is formed. *Isoamylcamphor*, from 50 g. (f) in 5 vols. MeOH treated with 520 g. of 3% Na-Hg in small portions, the soln. being kept neutral to phenolph. with 50% AcOH, *b*₁₄ 140°, *d*₄²⁰ 0.9197, [α]_D²⁰ 50.19°, 66.78°, 82.57°, 120.17° without solvent, 31.29°, 42.34°, 53.40°, 79.14° in C₆H₆ for C, D, E and F, *n* 1.46769, 1.47015, 1.47612, 1.4810 and *M* 67.12, 67.42, 68.15, 68.77 for α , D, β and γ . *Phenethylcamphor*, in 27 g. yield from 50 g. (g) similarly reduced, *b*₁₆ 201-2°, pointed prisms from dil. alc., *m.* 60-1°, [α]_D²⁰ 16.56°, 22.82°, 29.22°, 45.19° in C₆H₆ for C, D, E and F. *Phenylpropylcamphor*, *b*₁₅ 208-10°, *d*₄²⁰ 1.0008, [α]_D²⁰ 39.19°, 52.37°, 64.75°, 93.51° in C₆H₆ for C, D, E and F, *n* 1.52510, 1.52883, 1.52842 and *M* 82.75, 83.25, 84.51 for α , D and β .

CHAS. A. ROULLER.

Action of sulfur on indene, hydrindene and cyclopentadiene. I. WALTER FRIEDMANN. *Ber.* 49, 50-3 (1916); cf. Scheibler, *C. A.* 10, 340.—When 100 g. indene and 28 g. S are heated until reaction begins, then, after the boiling ceases, 2-3 hrs. at 180-5°, then 15 min. with a little PhMe, allowed to stand overnight and filtered, there is ob-

tained a dark brown powder which, after washing with PhMe and CS₂ and pressing on clay, assumes a yellow-green color; it is difficultly sol. in all solvents and by heating 15 min. on the H₂O bath 3-4 times with an insufficient amt. of C₆H₆ can be sepd. into 2 compds.; from the 1st exts. sep. yellow to yellow-brown leaflets of a *diindenethiophene*, C₆H₄.C—C.C₆H₄

$\begin{array}{c} | \quad || \quad || \quad | \\ \text{CH}_2-\text{C.S.C.CH}_2 \end{array}$, m. 290-2°, strongly fluorescent in C₆H₆, sol. in concd. H₂SO₄ with

intense emerald-green color, forms with C(NO₂)₄ a yellow-red addition product, reacts with Me₃SO₄, gives with cold concd. HNO₃ a *dinitro derivative*, red-violet crystals from PhNO₂, melts with decompn. The later C₆H₆ exts. of the reaction product deposit a flocculent substance which, combined with the portion not dissolved by the C₆H₆ and crystd. from cumene, yields pale yellow needles, m. 322-4°, of the compn. C₂₆H₂₄S. Hydrindene heated in a sealed tube with S gives in good yield a compound (C₈H₈)₂S, m. 290-2°. Dicyclopentadiene gives a compound C₁₀H₁₂S. CHAS. A. ROUILLER.

Dyes of the methylene blue group. I. Preparation of methylene blue as a lecture experiment. F. KEHRMANN, with R. SPEITEL. Univ. Lausanne. *Ber.* 49, 53-4 (1916); cf. *C. A.* 9, 1334.—1-2 g. thiodiphenylamine dissolved in so much warm AcOH that nothing seps. on cooling is treated with 5% Br in AcOH, with cooling and shaking, until the originally dark olive-green ppt. of the semiquinoid bromide becomes brown-red and cryst. (1-2 min.); it is immediately drained off, washed with a little Et₂O, suspended in 50 cc. of 96% alc. and at once treated with 5% alc. NHMe₃ until the soln. permanently smells of it; the brown-red perbromide quickly disappears, the soln. becomes dark green, then blue, and the dye soon begins to sep. in metallic green needles in almost quant. yield. The whole operation requires only about 10 min. The green intermediate product is dimethylaminophenazthionium bromide. C. A. R.

Catalytic hydrogenation of organic compounds with non-noble metals at room temperature. C. KELBER. Heilbronn. *Ber.* 49, 55-63 (1916).—The catalytic action of the reduced Ni metals is greatly increased if the compds. to be heated (best the basic carbonates) are first deposited on a suitable carrier (infusorial earth, Florida clay, the various com. hydrosilicates of Al and Mg, blood charcoal, the decolorizing charcoal of the ferrocyanide manufacture, linden charcoal, etc.). The reduction is best effected in aq. or aq.-alc. soln.; in alc., C₆H₆, Me₂CO, Et₂O and AcOEt it is slower; addition of a little H₂O, especially with Et₂O and AcOEt, greatly accelerates it; in AcOH it is rapid with Ni reduced at 310°; CHCl₃ is not suitable. To get an approx. comparison of the catalytic action of reduced non-noble metals with that of colloidal Pd, the detonating gas catalysis was carried out; the K. and Schwarz Pd prepn. (*C. A.* 6, 2757) was used; 0.2 g. of this (= 0.0344 g. Pd) showed an activity which at first was less than that of 0.5 g. Ni (a) (from the basic carbonate) reduced on 4.5 g. of an inorg. carrier in H at 450°, although it gradually increased as compared with the activity of the Ni and finally surpassed it. A Ni prepd. at 310° or 450° without a carrier gave a negative result. In the reduction of 0.75 g. PhCH:CHCO₂H in 50% alc., however, prepn. (a) and 3.0 g. Ni reduced at 310° without a carrier were about equally effective; 3.0 g. Ni reduced at 450° has about the same effect as 0.5 g. reduced at 310°, while 0.5 g. reduced at 450° without a carrier is enormously less effective than prepn. (a); in an aq. alc. soln. of PhCH:CHCO₂Na the Ni reduced at 310° has the same effect as an equal wt. of Ni reduced at 450° on a carrier. Co may be used instead of Ni, but the reduction is slower. Other substances reduced in this way were PhC:CCO₂Na, quinine-HCl, (PhC:C)₂, Na cottonoleate. Details of the various expts. (amts. of H absorbed in different time intervals) are given. CHAS. A. ROUILLER.

Phosphine sulfides and phosphine selenides. WILHELM STRECKER AND CHARLOTTE GROSSMANN. Marburg. *Ber.* 49, 63-87 (1916); cf. Sauvage, *Compt. rend.* 139,

674(1904).—Organo-Mg compds. act on PSCl_2 as on POCl_3 ; the reaction is smoother and more nearly homogeneous with aromatic than with aliphatic derivs. As the resulting phosphine sulfides are identical with those obtained by the action of S on phosphines and the P is undoubtedly pentavalent in these compds., and the reaction with the Grignard reagents takes place at low temps. and can be applied to much more sensitive compds. than PSCl_2 without rearrangement, it may be assumed that the P is also pentavalent in PSCl_2 , which therefore must have the structure $\text{S}:\text{PCl}_2$ and not Cl_2PSCl as assumed by some. The present work also disproves Vassilyev's belief that PSCl_2 is a eutectic mixt. of 1 part P_2S_5 and 3 parts PCl_5 (C. A. 5, 617), for neither of these compds. gives the above derivs. From 2.4 g. Mg and 15.7 g. PhBr in a little cold Et_2O slowly treated with 5.6 g. PSCl_2 , decompd. with H_2SO_4 and extd. with Et_2O is obtained PSPh_3 , needles, m. 161° (Michaelis and v. Soden, *Ann.* 229, 307(1885), give 157.5°). With PhCH_2MgCl , the reaction product decompd. with H_2SO_4 and treated with Et_2O deposits a white powder of $\text{PS}(\text{CH}_2\text{Ph})_3$, needles from CHCl_3 , m. 274° , while the Et_2O ext. yields *dibenzylhydroxyphosphine sulfide*, $\text{PS}(\text{CH}_2\text{Ph})_2\text{OH}$, leaflets from CHCl_3 , m. 171° , sol. in NaOH and in boiling soda, repptd. by HCl. From 2.4 g. Mg, 9.5 g. EtBr and 2 g. PSCl_2 is obtained *diethylhydroxyphosphine sulfide*, leaflets from ligroin, m. 76° . All attempts to prep. PSeCl_2 by methods analogous to those used in making PSCl_2 (addition of Se to PCl_5 , replacement of the O in POCl_3 by Se, reaction between PCl_5 and P_2Se_5) failed. It was hoped to attain the desired object by means of the reactions $\text{PhOPCl}_2 + \text{Se} \rightarrow \text{PhOPSeCl}_2 + \text{PCl}_5 \rightarrow \text{PSeCl}_2$, for when PhOPCl_2 is heated 0.5 hr. with S in sealed tubes at $220\text{--}30^\circ$ it gives PhOPSCl_2 ; from $(\text{PhO})_2\text{PCl}$ in an open dish at 200° is obtained $(\text{PhO})_2\text{PSCl}$, needles from alc., m. 63° , yielding with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ a *hydrazide*, $\text{PS}(\text{OPh})_2\text{N}_2\text{H}_4$, crystals from ligroin, m. $62\text{--}3^\circ$; $(\text{PhO})_2\text{PS}$, from $(\text{PhO})_2\text{P}$ and S at $180\text{--}90^\circ$, is unchanged by heating with excess of Hg. When, however, finely powdered Se is heated 2 hrs. in sealed tubes at 250° with PhOPCl_2 and the resulting red-brown liquid is distd. *in vacuo*, much PCl_5 first passes over, then a little unchanged PhOPCl_2 and finally *diphenoxychlorophosphine selenide* (a), together with a little *triphenoxyphosphine selenide* (b), but not a trace of PhOPSeCl_2 . This is due to the fact that PhOPCl_2 decomp. at a temp. below that at which Se is added, partly into $(\text{PhO})_2\text{PCl}$ and partly into $(\text{PhO})_2\text{P}$, together with PCl_5 . (a), b_{11} about 200° (slight decompn.), needles from MeOH, m. $59\text{--}9.5^\circ$, slowly turns pink in light and air, is obtained by heating 12.6 g. $(\text{PhO})_2\text{PCl}$ and 5 g. Se until the liquid becomes clear and slightly brown (about 260°) and keeping at this temp. for 10 min.; heated a long time at 180° , it decomp. into (b), Se and PCl_5 ; rubbed with PCl_5 , it liquefies and then solidifies to a solid which decomp. with deposition of Se when it is attempted to cryst. it from alc. or Et_2O ; C_6H_6 dissolves it slightly with yellow color but decompn. again occurs on concn., so that the reaction apparently has led to the formation of Se_2Cl_2 ; with PCl_5 in C_6H_6 is formed a brown-yellow mass, perhaps $\text{SeCl}_2\cdot\text{PCl}_5$. *Diphenoxiaminophosphine selenide*, from (a) in a little alc. slowly treated with concd. NH_4OH until the odor of the latter persists, cryst. scales from CCl_4 , m. 78° . *Hydrazino compound*, from (a) rubbed with $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$, needles from ligroin, m. 68° , reduces warm alk. Cu solns. (b) obtained by heating $(\text{PhO})_2\text{P}$ with excess of Se at 240° , needles from MeOH, m. $73\text{--}4^\circ$. The observation that the addition of Se takes place most easily with $(\text{PhO})_2\text{P}$ and becomes more difficult with increasing amts. of Cl made it seem possible that it was the strongly negative Cl, satg. so much of the P valence, which hindered the addition. Accordingly, the action of Se on the corresponding Br compds. was investigated. By the action of PBr₃ on PhOH and fractionation of the product *in vacuo* are obtained *phenoxydibromophosphine* (c), yellowish, mobile, refractive oil, b_{11} $130\text{--}2^\circ$, decomp. in the air, easily forms PBr₃ and $(\text{PhO})_2\text{P}$ on heating, and *diphenoxybromophosphine* (d), b_{11} $189\text{--}92^\circ$, somewhat

more stable towards air and H_2O than (c). Heated 15 min. at $150-60^\circ$ with 1 atom S, (c) gives PBr_3 and *phenoxydibromophosphine sulfide*, yellowish liquid soon becoming turbid, b_{11} $156-7^\circ$, slowly decompd. by H_2O . With Se no addition occurs. *Diphenoxybromophosphine sulfide*, from (d) and S cautiously heated to 160° , b_{11} about 200° (decompn.), needles from alc., m. 72.5° . *Selenide*, from (d) heated with Se until the liquid is clear and begins to turn brown (about 190°), crystals from ligroin, m. $64-5^\circ$, quite unstable. Replacement of the Cl by the more weakly negative Br, therefore, facilitates the addition of Se. When the halogen atoms are replaced by indifferent org. residues, Se is easily added (Pistschimuka, C. A. 6, 989); the influence of positive residues substituted for the halogen atoms could not be detd. for NH_3 and N_2H_4 , completely destroy the halogen compds. and org. bases yield the corresponding chlorides and oils containing N which on distn. give $PhOH$ and other products of deep-seated decompn. No addition of Te could be obtained in any case, so that the additive power of P for S, Se and Te decreases with increasing atomic wt. This is confirmed by the fact that (b) heated with S gives $(PhO)_2PS$ while the reverse reaction cannot be effected even with a large excess of Se. The fact that sulfones can be converted into selenides by fusing with Se (Krafft and Vorster, Ber. 26, 2813(1893)) is only an apparent contradiction and is due to the volatility of the replaced SO_2 group; the SO group cannot be so replaced. Substituents in the org. residues of the phosphines have no marked influence on the additive power of the P. From *p*-cresol and PCl_3 are obtained *p*-cresoxydichlorophosphine (e), b_{11} 118° , fumes in the air, decompd. by H_2O ; *di-p*-cresoxychlorophosphine (f), b_{11} $206-8^\circ$; and *tri-p*-cresoxyphosphine (g), b_{11} 285° (deposition of P). With 1 atom S at 220° , (e) gives *p*-cresoxydichlorophosphine sulfide, b_{11} $135-6^\circ$, attacked only very slowly by H_2O and even cold dil. NaOH. No selenide can be obtained. *Di-p*-cresoxychlorophosphine sulfide, from (f) and S at 180° , crystals from alc., m. $54-5^\circ$, probably identical with the product obtained by Autenrieth and Hildebrand from $PSCl_3$ and alk. MeC_6H_4OH (Ber. 31, 1108(1898)); *hydrazide*, crystals from alc., m. 141° . *Selenide*, from (f) heated with excess of Se at 200° until the soln. becomes brown, b_{11} 235° , needles from dil. alc., m. $48-9^\circ$; *hydrazide*, needles, m. $106-8^\circ$. *Tri-p*-cresoxyphosphine sulfide, from (g) and S at $140-50^\circ$, needles from alc., m. $93-4^\circ$, cannot be desulfurized by heating with Hg. *Selenide*, from (g) with excess of Se at 170° , needles from alc., m. $111-2^\circ$. *o*-Cresoxydichlorophosphine, b_{11} 116° ; *sulfide*, obtained at 230° , b_{11} $130-1^\circ$. *Di-o*-cresoxychlorophosphine, b_{11} $195-6^\circ$; *sulfide*, obtained at 205° , b. 212° (probably under 11 mm.—ABSTR.), slowly decompd. by boiling H_2O , yields a *hydrazide*, needles from alc., m. $89-91^\circ$; *selenide*, obtained at 220° , oil still containing much Se, b_{11} $224-7^\circ$, and giving a *hydrazide*, crystals from alc. and C_6H_6 , m. $98-9^\circ$. *Tri-o*-cresoxyphosphine, b_{11} 248° (slight decompn.), quite stable towards H_2O , alc. and even aq. NaOH; *sulfide*, obtained at $200-10^\circ$, b_{11} $280-90^\circ$, needles from alc., m. $45-6^\circ$; *selenide*, obtained at 240° , needles from alc., m. $50-1^\circ$. Mol. amts. of PCl_3 and *p*- ClC_6H_4OH at 150° give almost exclusively $(ClC_6H_4O)_2P$, m. 48° (Michaelis, Ber. 31, 1053(1898)), but by using a large excess of PCl_3 at 100° there are also obtained *p*-chlorophenoxydichlorophosphine, b_{11} $128-30^\circ$, and *di-p*-chlorophenoxychlorophosphine, b_{11} $225-7^\circ$. *p*-Chlorophenoxydichlorophosphine sulfide, obtained at 230° , b. $143-5^\circ$ (probably under 11 mm.—ABSTR.). *Di-p*-chlorophenoxychlorophosphine sulfide, obtained at $210-5^\circ$, b_{11} $243-5^\circ$, crystals from alc., m. $43-4^\circ$; the product described by Autenrieth and Hildebrand as m. 92° was probably not this compd. *Selenide*, obtained at 275° , b_{11} $245-55^\circ$, m. $59-61^\circ$. *Tri-p*-chlorophenoxyphosphine sulfide, needles from alc., m. $85-6^\circ$ (A. and H. describe a compd. m. $113-4^\circ$ to which they assign this structure), unchanged by hot NaOH, also obtained by heating the selenide (Michaelis) with S. *Tri-p*-nitrophenoxyphosphine, from PCl_3 and 3 mols. $O_2NC_6H_4OH$ 2 days at 90° , needles from AcOH, m. $170-1^\circ$, decomp. violently a few degrees above its m. p.

CHAS. A. ROULLER.

Partial acylation of polyvalent alcohols and sugars. II. EMIL FISCHER AND CHARLOTTE RUND. Univ. Berlin. *Ber.* 49, 88-105 (1916); cf. *C. A.* 9, 1183.—From finely powdered erythritol (a) shaken until dissolved with 6 parts Me_2CO containing 25% H_2O and 1% HCl , allowed to stand 17 hrs., freed from HCl with excess of Ag_2CO_3 , concd. *in vacuo* (most of the diacetone-erythritol distils over), boiled up with petr. ether to remove the last traces of the diacetone compd., extd. with Et_2O , concd. and treated with petr. ether there is obtained, in 50-5% yield of the (a) used (30-3% of unchanged (a) remains in the part insol. in Et_2O), monoacetone-erythritol (b), oil solidifying to leaflets, m. $75-6^\circ$, distils at a higher temp., tastes bitter but not so unpleasantly as the diacetone compd. With aq. instead of dry Me_2CO , mannitol (c) yields relatively more of the mono- and di- and less of the triacetone compds. (cf. *Ber.* 28, 1168 (1895)) but the mixt. is difficult to sep. In this connection was obtained a new β -diacetone-mannitol (d), m. about 85° higher than Irvine and Patterson's compd. (*C. A.* 8, 2341): 100 g. mannitol is shaken 3 hrs. with 2 kg. dry Me_2CO and 40 cc. HCl (d. 1.19), neutralized with PbCO_3 , drained, treated with a little Ag_2CO_3 , evapd. *in vacuo*, dissolved in 70 cc. hot alc., filtered, treated with much H_2O , filtered from the triacetone compd. (about 90 g.), evapd. *in vacuo* after adding Ag_2CO_3 , dissolved in warm H_2O (a further quantity of the triacetone compd. remains), the mother liquors evapd. again in the same way, the residue dissolved in 90 cc. hot C_6H_6 , filtered, treated with petr. ether to permanent turbidity and cooled to -20° ; the fine needles segg. (about 40 g.) are at once drained, pressed, dissolved in a little H_2O and cooled to 0° , whereupon there sep. fine needles which are again treated in the same way 1-2 times, finally giving 2-3 g. of (d) in long needles, m. $123-4^\circ$, $[\alpha]_D^{20} < -0.5^\circ$ in H_2O . It has been found that diacetoneglucose (e) can be prepd. much more easily from β - than from α -glucose: finely powdered β -glucose is shaken 36 hrs. with 20 parts dry Me_2CO containing 1% HCl , neutralized with PbCO_3 , filtered, evapd. with a little Ag_2CO_3 *in vacuo* not above 50° , extd. with 15-20 parts of ligroin (b. $110-20^\circ$) on the H_2O bath and cooled to 0° ; yield, 50%; this crude product in 25 parts cold H_2O with considerable concd. NaOH yields an oil quickly solidifying which, dissolved in AcOEt , evapd. *in vacuo* and crystd. from ligroin (b. 90°), gives 75% of pure (e), m. $110-1^\circ$ (cor.), $[\alpha]_D^{19} = -18.45^\circ$ in H_2O ; 50 g. heated 1.5-2.0 hrs. at 50° with 0.4 g. HCl in 800 cc. H_2O , shaken with Ag_2CO_3 , evapd. *in vacuo* not above 50° and extd. with AcOEt gives 80% of its wt. of monoacetone-glucose (f), m. $161-2.5^\circ$ (cor.), $[\alpha]_D^{22} = -11.82^\circ$ in H_2O . Dibenzoylacetone-erythritol, from 5 g. (b) heated 6 hrs. at 70° with 9.5 g. BzCl and 9 g. quinoline, microscopic prisms from MeOH , m. 70° , can be distd. in small amts.; a mixt. of aq. HCl and AcOH quickly attacks it, probably splitting off Me_2CO and giving as chief product dibenzoylerythritol which, however, is a thick oil, certainly different from the cryst. compd. obtained with the tri-Bz deriv. in the benzylation of erythritol in $\text{C}_6\text{H}_5\text{N}$ (*Ann.* 301, 101 (1898)). Di-*p*-bromobenzoylacetone-erythritol, obtained in the same way in 80-90% yield, microscopic needles from C_6H_6 -petr. ether, m. $147-8^\circ$ (cor.), gives with aq. HCl - AcOH a non-crystallizable oil, while 3 g. allowed to stand 48 hrs. in 66 cc. AcOH containing about 3 g. HCl gas yields 1.8 g. of α -diacetyldi-*p*-bromobenzoylerythritol (g), m. $83-6^\circ$ (possibly the compd. was not homogeneous). Diacetylacetone-erythritol, from 5 g. (b) allowed to stand 24 hrs. in 12.6 g. Ac_2O and 12.5 g. $\text{C}_6\text{H}_5\text{N}$, mobile bitter oil, b.p. $115-20^\circ$, probably not homogeneous, for when 5 g. is shaken with 50 cc. of 0.5 *N* HCl until dissolved (about 10 min.) and allowed to stand 1 hr. it yields almost quant. an oil, b.p. $158-65^\circ$ (bath temp.), having the compn. of diacetylerythritol, but on long standing (1 week) it partially solidifies to crystals segg. from Et_2O -petr. ether in long slender prisms or shorter forms, m. $89-91^\circ$, of the same compn., having a faintly bitter taste and forming an aq. soln. neutral to litmus; heated 6 hrs. at 65° with 2.5 parts *p*- $\text{BrC}_6\text{H}_4\text{COCl}$ and 2.8 parts quinoline they yield β -diacetyldi-*p*-bromobenzoylerythritol.

crystals from C_6H_6 , m. $150-2^\circ$, isomeric with (g) above. *Tribenzoylacetoneglucose*, in 82.5% yield from 5 g. (f) heated 7 hrs. at 65° with 11.2 g. $BzCl$ and 11 g. quinoline, m. $119-20^\circ$ (cor.), decomps. to a great extent at higher temps., does not reduce Fehling soln. in dil. alc., $[\alpha]_D^{23} -91.95^\circ$ in CCl_4 ; 3 g. in 36 cc. $AcOH$ allowed to stand 0.5 hr. with 18 cc. HCl (d. 1.19), decompd. with ice, extd. with Et_2O , shaken with concd. $KHCO_3$, washed with H_2O , and evapd. *in vacuo* gives *tribenzoylglucose* (h) as an oil solidifying in the cold, sol. in warm CCl_4 and sepg. on cooling in needles or prisms with 1 mol. CCl_4 , sinters from 65° , foams 80° , with loss of the CCl_4 , $[\alpha]_D^{20} -75.24^\circ$, -76.12° , -77° , -85° , -91.7° in 3, 5, 8, 38 min., 20 hrs., resp., after soln. in alc.; the crystals with $KOAc$ in alc. and $H_2NCONHNH_2.HCl$ in H_2O yield a substance having approx. the compn. of the expected semihydrazone (C and N about 1 and 0.5%, resp., too low). (h) could not be obtained cryst. from any other solvent. *p-Bromobenzoyldiacetoneglucose*, in 85% yield from 10 g. (e), 9 g. BrC_6H_4COCl and 12 g. quinoline 6 hrs. at 70° , long, often lancet-shaped needles from alc.- H_2O , sinters 78° , m. $79-80^\circ$, does not reduce Fehling soln. in dil. alc. soln., $[\alpha]_D^{19} -49.24^\circ$; 4 g. in 40 cc. $AcOEt$ and 20 cc. HCl (d. 1.19) 1.5 hrs. at 30° gives *p-bromobenzoylglucose* (i), amorphous, also obtained by heating 1 g. of the diacetone compd. with 10 cc. of a mixt. of 9 parts of 50% $AcOH$ and 1 part HCl (d. 1.19) up to 55° until soln. results and keeping 50 min. at 50° ; it has an extraordinarily bitter taste and strongly reduces Fehling soln., gives an oil on warming with $PhNHNH_2.HCl$ and $NaOAc$ in H_2O , is partially reconverted into the diacetone compd. by Me_2CO and HCl ; at 100° it slowly becomes faintly yellow-brown and after 75 min. is mostly converted into a substance very difficultly sol. in hot H_2O , in which it melts to an oil, only faintly reduces Fehling soln. If the operation is carried out in a high vacuum the mass also swells up and when so prepd. apparently contains 1 mol. less of H_2O . (i) in $MeOH$ shows $[\alpha]_D^{19} 26.8^\circ$, 27.4° , 28.8° , 44° in 14, 31, 64 min., 14 days after soln.

CHAS. A. ROULLER.

An occurrence of indole and skatole. EDMUND O. VON LIPPMANN. *Ber.* 49, 106-7(1916).—In the desaccharification of beet molasses by the Sr or Ba process the vapors evolved from the molasses on long boiling with excess of the alk. earth have a foul, at times almost unbearable fecal odor. While investigating the possibility of utilizing the NH_3 in these vapors v. L. from certain condensates isolated indole, from others skatole and from still others a mixt. of these 2 compds. Among other substances, v. L. has isolated from the juice of etiolated sprouts growing from stacked beets what he believes to be *L-phenylalanine*, $C_9H_{11}O_2N$, stars, m. 264° (decompn.), $[\alpha]_D^{20} -35.3^\circ$ in H_2O ; *L-tryptophan*, $C_{11}H_{13}O_2N_2$, leaflets, m. 287° , $[\alpha]_D^{20} -32.8^\circ$ in H_2O , showing *d*-rotation in HCl and alk. soln.; and in the phosphotungstic ppts. a small amt. of a base, $C_{14}H_{19}O_2N_2$, leaflets, m. 256° , $[\alpha]_D^{20} 96^\circ$, yielding well-crystd. compds. with mineral acids and giving with boiling alkalis NMe_3 and indole among other products; it would seem to be Grashoff and van Romburgh's heptaphorine (*Chem. Zentr.* 1911, I, 1548).

CHAS. A. ROULLER.

Hydroxymethylenebutanone and a new method of formation of hydroxymethylene compounds. OTTO DIEHL and KONRAD ILBERG. *Ber.* 49, 158-64(1916).—From 11.4 g. freshly distd. $AcC(:N_2)Me$ (C. A. 9, 1180) and 10 g. of 35% aq. $HCHO$, cooled so the temp. does not rise above 60° , allowed to stand 3 days and distd. under 14 mm. there is obtained around 90° about 5 g. of a distillate quickly solidifying to crystals imbedded in a strongly smelling liquid from which they are best sepd. by slow sublimation, giving 2-3 g. of pure *hydroxymethylenebutanone* (a), $AcC(:CHOH)Me$. (a) is better obtained by slowly treating a suspension of dry, alc.-free $NaOEt$ (from 32 g. Na) in 1 l. cold Et_2O with 100 g. $AcEt$ and 102 g. acid-free HCO_2Et in 100 cc. cold Et_2O , allowing to stand some time at 0° , draining the stiff yellowish magma, washing with Et_2O , removing the adherent mother liquors by long-continued pressing, treating

the dried residue (150 g.) in a little ice H_2O with cold dil. H_2SO_4 , extg. with Et_2O , drying carefully and slowly distg.; the distillate partially solidifies on cooling and the filtrate from the solid yields a further crop of (a) on distn. *in vacuo*; slow sublimation of the crude product gives 15–20 g. pure (a), leaflets of a characteristic sweetish and rancid odor, m. 73° , b. $145-7^\circ$ (some decompn.), quite volatile, quickly disappearing when spread on clay; in a sealed tube it remains unchanged for some weeks but gradually turns yellow, then dirty red, and on opening under H_2O the tube sucks in 0.2 of its vol. of H_2O , showing that O had been absorbed. With a few drops of $FeCl_3$, dil. aq. solns. assume an intense $KMnO_4$ -red color; $NH_3 \cdot AgNO_3$ is not reduced even on heating and Fehling soln. only on warming and very slowly. *Copper salt*, from (a) in H_2O and $Cu(OAc)_2$, dark green prisms from alc., m. $157-8^\circ$, decomp. suddenly above the m. p. with evolution of acid-smelling vapors. (a) treated in Et_2O with HCl gas or heated 1 min. at 100° with 37% HCl gives a *hydrochloride*, $C_8H_8O_2 \cdot HCl$, iridescent sharp-angled tables from warm H_2O or $AcOEt$, turns brown about 90° , decomp. about 107° , quite as volatile as (a), reconverted into (a) by boiling H_2O or cold dil. alkalies. From 2.5 g. (a) in luke-warm H_2O treated with 1.25 g. $N_2H_4 \cdot H_2O$ is obtained 1.5 g. of 4,5-dimethylpyrazole. *Anil* of (a), in 2.9 g. yield from 2 g. (a) in 4 cc. warm $MeOH$ and 1.9 g. $PhNH_2$, needles from $AcOEt$, m. $125-6^\circ$. When 30 g. BzH in 105 cc. of 37% HCl is slowly treated with 15 g. (a), allowed to stand 10 days and cautiously crystd. from C_6H_6 , there is obtained 12 g. of a *dibenzalbutanone hydrochloride*, $PhCH:CHCOC(:CHPh) \cdot Me \cdot HCl$ or possibly $AcC(:CHPh)CH:CHPh \cdot HCl$, leaflets, sinters about 150° , m. $158-9^\circ$. *Hydrobromide*, similarly obtained with HBr , prisms, m. $149-51^\circ$. Attempts to obtain the free butanone from these salts have thus far failed. C. A. R.

Degradation of scopoline. ERNST SCHMIDT. Marburg. *Ber.* 49, 164–8 (1916).—S. accuses Hess and Suchier (*C. A.* 10, 770) of invading his field and shows, by references to his papers, that he had already proved that scopoline belongs to the piperidine series. CHAS. A. ROULLER.

Products of the decomposition of aluminium phenolates by heat. RICHARD MÖHLAU. Dresden. *Ber.* 49, 168–71 (1916).—A more exact study has shown that the compds. $C_{12}H_{10}O$ (a), obtained in small amt. together with Al_2O_3 , C_6H_6 hydrocarbons, phenols and phenol ethers by heating Al phenolates (Gladstone and Tribe, *J. Chem. Soc.* 1886, 25, and earlier papers) are xanthenes and that the decompn. may be represented by some such scheme as $2(PhO)_3Al \longrightarrow 2Al_2O_3 + 10C + 2H + CH_4 + C_6H_6 + 3PhOH + 2Ph_2O + (a)$. The formation of (a) may probably be explained by the assumption that, as the result of pyrogenic synthesis, CH_4 and $PhOH$ form *o*- MeC_6H_4OH which condenses with another mol. of $PhOH$ to (*o*- HOC_6H_4) $_2CH_2$ which then goes over into (a). The compd. $C_{12}H_{14}O$, m. 186° , obtained by G. and T. from (*p*- MeC_6H_4O) $_2Al_3$ is doubtless 2,7-dimethylxanthene, and the compd., m. 200° , obtained from the thymolate, is 3,6-dimethylxanthene, for propylene is formed at the same time, showing that the connecting CH_2 has entered the position occupied by the displaced iso-Pr group. Finally, the compd. $C_{12}H_{14}O$ obtained from the *o*-cresylate is 4,5-dimethylxanthene. Of the 3 "pyrocresols" obtained in the distn. products of crude carboxylic acid (Zmerzlikar, Sr., *Z. angew. Chem.* 1893, 468; Schwarz, *Ber.* 15, 2201 (1882); 16, 2141 (1883)), the α -compd., m. 195° , which has been identified as 3,6-dimethylxanthene (Zmerzlikar, Jr., *C. A.* 5, 1770), is doubtless identical with G. and T.'s (b). CHAS. A. ROULLER.

Nitrosoarylhydroxylamines. I. The influence of nucleus substitution on groups forming inner complex salts. OSKAR BAUDISCH. Univ. Zurich. *Ber.* 49, 172–80 (1916).—The property of $PhN(NO)OH$ of forming inner complex salts only with Fe, Cu, Ti and Zr is not changed by the introduction into the C_6H_5 nucleus of Cl, Br, NO_2 , Me or MeO; the introduction of acid groups only makes the inner metallic com-

plex salts more stable but has no apparent influence on the secondary valence union of other metals. When, however, groups like $\text{MeC}_6\text{H}_4\text{SO}_3$, HO , $\text{MeC}_6\text{H}_4\text{SO}_3\text{NH}$, $\text{MeC}_6\text{H}_4\text{SO}_3\text{NMe}$, Me_3N , OHC , are introduced in the *o*- or *m*-positions, the power of forming complex salts is extended to almost all the other metals. Almost all inner complex salts still have residual affinities available and are capable of combining with new mols.; qual. expts. have shown that the complex salts of the nitrosoaryhydroxylamines can combine with acids, bases, neutral salts and gases, the ability to combine varying with the nature of the metal and with the entrance and variation of substituting side chains. B. discusses the probable physiological importance of these facts, taking as an example the observation of Unna that of the various hydroxyanthracene, -anthranol and -anthraquinone derivs. only those hydroxyanthranol compds. with an HO group in the *p*-position to the C:O group have an extraordinarily powerful anti-psoriatic effect. II. Inner metallic complex salts of *o*-nitrosohydroxylaminophenyl *p*-toluenesulfonate. OSKAR BAUDISCH, H. GUREWITSCH AND S. ROTHSCILD. *Ibid* 180-90.—The NH_4 salt (*C. A.* 6, 2600) was the starting point for the prepn. of the following salts. The pure salt is very easily sol. in the purest distd. H_2O but if the latter contains only traces of inorganic salts the soln. becomes turbid; clear solns. in distd. H_2O give with ordinary H_2O a thick ppt., the salts imparting hardness to H_2O being thereby quant. pptd. All the salts below, of the general structure $\text{MeC}_6\text{H}_4\text{SO}_3\text{C}_6\text{H}_4\text{N}(\text{O}):\text{NOM}$ (M = metal + valence), are strikingly easily sol. in org. solvents, the Cu salt alone being an exception; in H_2O they are all practically insol.; all are able to combine with new mols., as shown by the change in color or soly. when brought together with acids, bases or neutral salts. The Co salt is difficultly, the Ni salt easily sol. in cold PhMe, but the difference is not sufficient to permit of a quant. sepn. of the 2 metals. The Co salt in Me_2CO , however, gives with aq. KCN a dark brown ppt. sol. in dil. HCl with light yellow color, while the Ni salt is merely decolorized by KCN but forms no ppt. *Cobalt salt*, from cold aq. solns. of the NH_4 salt and 0.6 part $\text{Co}(\text{NO}_3)_2$, obtained as a faintly pink cryst. powder after several pptns. from CHCl_3 with ligroin, sol. in CHCl_3 with faint yellow-red color; HCl gas turns the soln. momentarily blue and gives a ppt.; NO after a time produces a turbidity; the C_6H_6 soln. has the same color as the CHCl_3 soln., HCl decolorizing it and producing a white ppt.; slightly warm PhMe gives a blood-red soln. changing to green on heating, while further heating produces decompn. and sepn. of a brown-yellow ppt.; Me_2CO gives a faintly yellow soln. turned green by NO; on long standing the green soln. again becomes yellow; HCl likewise produces a green color, H_2S a black ppt., KOH produces no change, KNO_3 gives a milk-white ppt. The AcOEt soln. is reddish yellow, HCl turning it blue, then green. NH_4OH gives a faintly yellow, $\text{C}_6\text{H}_5\text{N}$ a deep red soln.; in the latter on heating there is partial decompn. and deposition of a brown-yellow ppt. Warm dil. HCl gives a blue-green soln.; prolonged heating produces decompn. with sepn. of an oil. The following salts were prepd. in the same way: *nickel*, green crystals; *ferric*, yellow; *chromic*, gray; *uranyl*, intensely yellow; *plumbic*, white; *bismuth*, faintly yellow; *mercuric*, white, becoming yellow in 2-3 days, then yellow-green; *cerium*, yellow; *lanthanum*, white needles with Ag luster from AcOEt -petr. ether; *thorium*, white; *aluminium*, *cadmium*; *cupric*, green-blue. For details as to the behavior of the salts towards various solvents and reagents, cf. the original. III. Inner metallic complex salts. OSKAR BAUDISCH, A. E. PISTOR AND B. SILBERBLATT. *Ibid* 191-202.—*o*-Nitrophenyl *o*-toluenesulfonate, from 7 g. $\text{o-O}_2\text{NC}_6\text{H}_4\text{OH}$ and 2 g. NaOEt in 400 cc. alc. heated on the H_2O bath with 10 g. $\text{MeC}_6\text{H}_4\text{SO}_2\text{Cl}$ until the red color changes to yellow (about 1 hr.), leaflets from alc., m. $131-4^\circ$; 5 g. suspended in 700 cc. alc. treated with frequent shaking with NH_3 , heated some time on the H_2O bath, then treated with H_2S in ice-salt until the soln. is completely filled with $(\text{NH}_4)_2\text{S}$ crystals (3-4 hrs.),

allowed to stand 24 hrs. in the ice chest, filtered, poured into 5-6 l. of ice-cold distd. H_2O and allowed to stand 2 days or more in the ice chest, gives the *o*-hydroxylamino ester, silvery needles, m. 64° ; treated in C_6H_6 or Et_2O with excess of NH_3 , then, with continuous stirring, with about the calcd. amt. of $AmNO_2$ and allowed to stand 15-20 min., it gives the ammonium salt of the nitrosohydroxylamino ester, $MeC_6H_4SO_3C_6H_4N(NO)ONH_4$, needles from alc., m. $118-22^\circ$ (decompn.), slowly turns brown in the air, easily sol. in distd. H_2O with faintly yellow color, the soln. giving a voluminous ppt. with tap H_2O . From the NH_4 salt were prepd. the following salts: cupric, gray-blue flocks; plumbic, white needles from C_6H_6 ; cobalt; nickel, greenish white; neodymium, voluminous light blue flocks; lanthanum, snow-white, turns superficially brown in the air; praseodymium, white with a greenish yellow tinge; erbium, yttrium, thorium, magnesium, all white. *p*-Toluenesulfonyl-*m*-nitroaniline (a), obtained in 10-2 g. yield from 6.9 g. $O_2NC_6H_4NH_2$, 9.5 g. $MeC_6H_4SO_3Cl$ and 2.5 g. $NaOAc$ heated 3 hrs. on the H_2O bath in 800 cc. H_2O , needles from $EtOH-H_2O$, m. 139° , converted by NH_3 and H_2S in 96% alc. into the aminophenylhydroxylamine, leaflets, which with NH_3 and $AmNO_2$ in $CHCl_3$ gives the ammonium salt of *p*-toluenesulfonyl-*m*-aminonitrosophenylhydroxylamine, m. 165° (decompn.); acidified in cold H_2O in the presence of Et_2O with HPO_4 , it gives the free hydroxylamine, scales from Et_2O , m. $109-11^\circ$, quickly decomps. in the air. From the NH_4 salt are obtained the following salts: Ferric, red-brown; cupric, light blue; cobalt, light pink; nickel, light green. *p*-Toluenesulfonyl-*N*-methyl-*m*-nitroaniline, from 5 g. (a) in a little 20% $NaOH$ shaken with 10 g. Me_2SO_4 , again treated with 5 cc. $NaOH$ and 3 g. Me_2SO_4 and heated at $40-50^\circ$ until alkali no longer produced a yellow color, treated with 20 cc. $NaOH$ and heated on the H_2O bath to destroy the excess of Me_2SO_4 , slender needles from alc., m. 111° . Aminophenylhydroxylamine, needles from C_6H_6 , m. 119° . Ammonium salt of the aminonitrosophenylhydroxylamine, snow-white crystals from $EtOH-Et_2O$, decomps. $134-48^\circ$, very unstable in the air and light. Metallic salts: plumbic, white; nickel, very faintly greenish yellow crystals from C_6H_6 , decomps. 135° ; cobalt, reddish gray; chromic, light yellow, yttrium, snow-white; aluminium, white. IV. Inner metallic complex salts. OSKAR BAUDISCH AND HERMANN ROM. *Ibid* 203-10.—*m*-Dimethylaminophenylhydroxylamine, from $m-O_2NC_6H_4NMe_2$ in alc., m. $107-8^\circ$, gradually darkens, reduces cold Fehling soln. and NH_3-AgNO_3 , colors the skin brown-black, produces sneezing, gives with NH_3 and $AmNO_2$ in Et_2O the ammonium salt of *m*-dimethylaminonitrosophenylhydroxylamine, fine silvery needles, becomes brown and insol. in H_2O in 1-2 hrs.; if it is dissolved in hot alc. and allowed to evap., red-violet needles of a peculiar odor sep.; they appear brown when rubbed, are insol. in H_2O but sol. in dil. HCl with red color; with $FeCl_3$ like the silvery NH_4 salt, they give in HCl an intense red color. Cupric salt, canary-green ppt., sol. in acids with dark red color. Ferric salt, dark brown ppt. becoming light brown on drying, sol. in Et_2O with red color, purified by pptn. from $CHCl_3$ with ligroin or petr. ether; it thereby becomes brown-black with a violet tinge. Thorium salt, light green crystals from $CHCl_3$, m. 151° , becomes yellow on heating. Neodymium salt, yellow. Cobalt salt, flesh-colored, decomps. about 110° . Praseodymium salt, white, decomps. 145° . Neodymium salt, yellow-green. Lanthanum salt, light yellow. For details of the prepn. and behavior towards various solvents of these salts, cf. the original.

CHAS. A. ROYLER.

The Wagner-Saytzeff reaction in olefin aldehydes. C. J. ENKLAAR. The Hague. *Ber.* 49, 211-3 (1916).—Allylisoallylcarbinol (C. A. 7, 1704) has now been obtained pure (yield, 48.7% boiling within 3° , 16.5% boiling within 1°) from 336.6 g. allyl bromide, b. $69.3-9.7^\circ$, and 21.2 g. crotonaldehyde, b. $102.2-2.5^\circ$, in an equal vol. of Et_2O slowly added to 19.7 g. Zn wool in a flask filled with CO_2 , gently heated to start the reaction; when the whole of the mixt. has been added, with cooling, in the course

of several hrs., it is heated 0.5 hr. to boiling, poured into H_2O , acidified with dil. H_2SO_4 , extd. with Et_2O , washed with $NaHCO_3$ and H_2O , dried with $CaCl_2$ and fractionated under 24 mm. in CO_2 . The carbinol b_{788} $156-6.7^\circ$ (decomp. into H_2O and higher boiling products), $d_4^{14.8}$ 0.8668, n 1.45193, 1.45527, 1.46294, 1.46959 for α , D, β and γ , resp., M 34.892, 35.116, 0.729, 1.157 for α , D, $\beta - \alpha$ and $\gamma - \alpha$. Tiglic aldehyde and methylethylacrolein also yield alcs. under these conditions. C. A. ROULLER.

The isomerism of the benzil- α -carboxylic acids and their derivatives. A. HANTZSCH AND A. SCHWIETE. *Ber.* 49, 213-26(1916); cf. C. A. 9, 2252.—The acids, salts and esters exist in chromoisomeric series: yellow keto forms, $ArCOCOC_6H_4CO_2R$ ($R = H$, alkyls, metals), and colorless hydroxylactone forms, $O.CO.C_6H_4.C(OR)COAr$.

The corresponding acid chlorides are not chromoisomeric, both forms being colorless. Of the 3 possible series of the di- CO_2H derivs., only 2, the diketoid and the dilactoid, have thus far been obtained. The constitutions of the isomeric series were detd. both optically and chemically; the yellow series give absorption curves very similar to those of benzil, just as the curves for the ketoid esters of $o-BzC_6H_4CO_2H$, the corresponding salts and the free acid are similar to that for $BzPh$, while the colorless esters show absorptions very like those of the lactoid esters of $BzC_6H_4CO_2H$. Of the 2 forms of chlorides, 1 reacts like a true acid chloride with H_2O and alcs., while the other is so indifferent that it can be recrystd. from hot alc. The yellow salts, as derivs. of true keto acids, are stable in alk. soln. The yellow esters are much more easily hydrolyzed than the colorless esters. The presence or absence of color, however, is not sufficient to characterize any given form as ketonic or lactoid; thus, both forms of chlorides are colorless; the colorless lactoid di- CO_2H acid and its esters dissolve in concd. H_2SO_4 with yellow color, the yellow ketoid esters without color; the latter solns. gradually become yellow, owing to the conversion of the ketoid ester into the lactoid acid. Of the di- CO_2H acid, only the colorless form has thus far been obtained, but indirect evidence of the existence of chromoisomerism is furnished by the fact that colorless and yellow salts are known and that the colorless alkali salts when heated at about 130° become yellow without melting and on cooling remain yellow for quite a long time. The acids and salts, being electrolytes, yield mixts. of both forms, equil. being reached from either side with immeasurable velocity; the equil. always lies far towards the side of the yellow ketoid forms; in the case of the salts, only the ketoid form exists in soln., the solns. being optically identical with those of the ketoid esters and not changed by excess of alkali, but this cannot be said with equal certainty of the free acids. Nothing can be added to Graebe's description of the 2 forms of $o-BzCOC_6H_4CO_2H$ (*Ber.* 23, 1344(1890)) except that it cannot be concluded from mol. wt. detns. that both have the same mol. wt., for solns. of the colorless acid (even in $CHCl_3$ at -40°) at once become yellow and optically identical with those of the yellow acid. All the alkali and alk. earth salts are yellow but, with the exception of the Ca salt which melts in its H_2O of crystn. when heated, are obtained as syrups gradually solidifying to glass-like masses. Only the cryst. silver salt is colorless but dissolves with yellow color in warm H_2O and MeCN. Lactoid chloride, from the acid heated about 8 hrs. with excess of $SOCl_2$ at 80° until the soln. is almost colorless, m. 128° . True acid chloride, from the acid in CS_2 heated with excess of PCl_5 , crystals from C_6H_6 or $CHCl_3$, m. $61-3^\circ$, decomp. into anthraquinone when distd. *in vacuo*, converted by long heating in $CHCl_3$ into its isomer. Ketoid methyl ester, m. 117° . The colorless esters could not be obtained, even the lactoid chloride and Na alcoholates in alc. or indifferent solvents and the colorless Ag salt alone or in MeCN with alkyl halides giving the yellow esters. ($o-HO_2CC_6H_4CO$) $_2$, from diphthalylactonic acid (Reissert, C. A. 7, 2578) and $KMnO_4$, m. 273° . Lithium salt, colorless but becomes intensely yellow at 130° . The colorless

ammonium salt gives the acid on heating. All methods of prepn. of the chlorides yield mixts. of both forms, the lactoid predominating; the latter partially seps. in rhombic crystals, m. $250-3^{\circ}$, when the acid is heated with excess of SOCl_2 10 hrs. at 130° ; the remainder is obtained by evapg. the SOCl_2 , digesting with cold C_6H_6 and recrystg. the residue from hot C_6H_6 ; it is identical with the product obtained from diphthaly and PCl_5 (Ador, *Ann.* 168, 236) and can be boiled for hrs. with alc. without change. The ketoid chloride, obtained from the cold C_6H_6 ext. above, m. $194-6^{\circ}$, is always obtained only in small amt., even with P chlorides. The yellow esters can be obtained from the Ag salt with alkyl halides, the ketoid chloride with alcs. and also from a suspension of the lactoid chloride in hot MeOH slowly treated with dil. NaOMe until it just dissolves with yellow color. The colorless esters are obtained from the acid with alcs. and HCl (cf. Juillard, *Ann.* 242, 229; Hönigsberger, *Ibid* 311, 266); contrary to the conclusions of J. and H., however, they are di-, not monoalkyl, esters; heated several hrs. in alc. at about 200° , in the presence of a trace of HCl, they are converted into the ketoid esters. Mol. wt. of the yellow di-Et ester in alc. 337; of the colorless ester in AcOH 330, 345.

CHAS. A. ROUILLER.

Optical anomalies of fluorenone- and allochrysoketone-1-carboxylic acids. A. HANTZSCH. *Ber.* 49, 226-32 (1916); cf. Stobbe, *C. A.* 9, 1772; Schaarschmidt, *C. A.* 10, 341.—The fact that fluorenone-1-carboxylic acid (a) is cinnabar-red and allochrysoketone-1-carboxylic acid (b) Bordeaux-red, while the salts and esters of both are only gold- to orange-yellow seems contradictory to H.'s observation that org. acids and their esters do not differ materially in their absorption and that the corresponding alkali salts may often be more strongly but never, as in the above cases, more faintly colored. In the belief that this anomaly might be due to chromoisomerism similar to that described in the preceding abstr., all the methods there used to prep. the isomeric esters, chlorides and salts were applied to (a) and (b) but without success. Since the yellow solns. of (a) and (b) are similar to the yellow solns. of $\text{BzCOC}_6\text{H}_4\text{CO}_2\text{H}$ and the acids are therefore certainly ketoid, the lactoid forms, if they existed, should be colorless or at least much lighter. The dark (a) and (b) can therefore not be the hydroxylactone forms and must be constitutionally changed forms of the true ketonic acids. Since these 2 acids are the only ones also characterized by a firmly fixed adjacency of the C:O to the CO_2H group, their abnormal color probably depends on some intramol. reaction between these 2 groups. Since the hydroxylactone form is excluded and a superoxide-

like ring (I) is improbable, there only remains the inner oxonium salt structure (II). This explains all the optical anomalies of (a) and (b). (a) has the same cinnabar-red color as the external oxonium salt, fluorenone nitrate, $\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{C}:\text{O}:\text{O}:\text{HNO}_3$ (Meyer,

C. A. 4, 1142), and just as the latter is resolved into its components by solvents, so (a) in sufficiently dil. alc. solns. assumes the yellow color and the absorption of the true ketoid ester. This also explains why fluorenone-4-carboxylic acid, isomeric with (a), is optically normal, being yellow; the C:O and CO_2H groups are sepd. so far intramol. that they cannot form the inner oxonium salt. Moreover, this view is in harmony with the fact that the color of (a) and (b) in soln. depends enormously on the solvent, being normal (*i. e.*, almost identical with that of the ketoid esters) in indifferent solvents like alc. and CHCl_3 , but increasing and approaching that of the solid acids with

increasing acidity in the solvent; thus, in AcOH they are already considerably darker than in alc. while in $\text{CCl}_4\text{CO}_2\text{H}$ they are cinnabar-red and Bordeaux-red, resp. In other words, in indifferent solvents the solid, dark oxonium salts are almost completely "hydrolyzed" to the true open ketoid forms, but in strong acid media they exist as inner oxonium salts or oxonium salts of the medium. One point remains to be explained: in concd. H_2SO_4 (a) and (b) dissolve with colors even deeper than those of the solid acids (Bordeaux-red and deep brown-violet, resp.). This may be due to the fact that even in the solid form the acids do not exist wholly in the oxonium salt form but consist of solid solns. of the salts in the yellow ketoid form and are only completely converted into the oxonium salts when dissolved in concd. H_2SO_4 , or it may be that a dioxonium sulfate (III) is formed. This is rendered probable by the fact that compds. like AcOH and BzOH form oxonium sulfates in concd. H_2SO_4 and show much stronger absorption in this than in other solvents.

CHAS. A. ROULLER.

Alleged isomerism of formanilide. A. HANTZSCH. *Ber.* 49, 232-3 (1916).—Of the 2 supposed isomers of HCONHPh , m. 46° , obtained by Orlov by heating glycerol monoformate (a) with PhNH_2 (*J. Russ. Phys. Chem. Soc.* 37, 439), the liquid product is impure $\text{HO}_2\text{CCONHPh}$ and that m. 245° is $(\text{CONHPh})_2$. They are obtained only when the crude (a) (prepd. by heating glycerol with (CO_2H) , up to 180°) is used; pure (a), b.p. 165° , does not react with PhNH_2 under the conditions given by O. C. A. R.

Chromoisomerism of the phenol aldehyde salts. A. HANTZSCH. *Ber.* 49, 234-6 (1916); cf. C. A. 9, 3234.—Reply to Pauly (C. A. 10, 478). C. A. R.

Rearrangement of iso into tertiary butyl bromide. A. MICHAEL, E. SCHARF AND K. VOIGT. *J. Am. Chem. Soc.* 38, 653-75 (1916).—As previously shown (C. A. 7, 784) the isomerization of iso-BuBr (a) into Me_3CBr (b) depends to a remarkable degree on the purity of the (a), very small amts. of certain substances being capable of retarding it almost completely at temps. at which the pure product changes rapidly. The present work was undertaken to det. the conditions for prepg. a purer (a) and study its rearrangement quant. but the purer (a) is so extraordinarily unstable and sensitive to positive and negative catalysts that it has not been possible to obtain more nearly const. results than in the earlier work. The purest (a) is obtained by heating very pure iso-BuOH and HBr at 65° , the alc. being purified by fractionation and conversion into the boric ester and the HBr prepd. from electrolytic H and very pure Br. It cannot be distd. once without forming HBr or rearranging to some extent into (b); the latter change even takes place slowly in a brown desiccator at room temp. It often becomes brown at 108° , can be heated only a short time at 142° and totally decomp. at 260° . Dissociation could not be detected in the gaseous state at 142° in a Meyer app.; at 184° the amt. of gas obtained at once corresponded to the normal vapor density, then for the next 20 min. gas was slowly evolved until about 50% of the (a) was dissociated, but that rearrangement occurs intramol. in the gaseous state is shown by the fact that (b) is formed even at 100° . Asbestos, glass wool, sand, etc. (cf. Konowalow, *Ber.* 18, 2808 (1885)), produce no dissociation at 142° ; even powdered "Geraete" glass, which considerably affects the rearrangement in the liquid state (see below), has no influence in the gaseous state. The earlier observations on the action of negative catalysts on the liquid have been confirmed with the purer (a); small amts. of diisobutene, iso-BuOH and Me_3COH greatly decrease the rearrangement and the limit of the reaction. Ground surfaces (glass or quartz) also act as negative catalysts in the liquid state, the isomerization being more retarded in quartz than in glass. The retardation is probably due to the formation of minute amts. of by-products. With the pure (a) the limit of (b) formation was found to be 69.1-75.5% at 142° , 67.6-73.2% at 184° and 19.8-20.2% at 108° . In Jena "Geraete" glass the rearrangement is almost

3 times as fast as in Jena hard and ordinary soft glass, the glass either acting directly as a catalyst or through the formation of another compd. by the action of the (a) on it; if the latter assumption is correct, the amt. of new compd. formed must be infinitesimal, for no solid residue is obtained on boiling the powdered glass a long time with (a) and evapg. the liquid. The main difference between the "Geraete" glass and the other kinds of glass used is that it contains ZnO, and it was found that about 0.0001% ZnBr₂, as a matter of fact, almost doubles the rearrangement, whereas 0.0004% only increases it about 25% and causes the formation of small amts. of colored by-products, while with appreciable amts. of the salt the product is dark and contains no (b). No Zn could be detected in HBr with which "Geraete" glass had been digested some hrs. Vessels of this glass are less active on 2nd use but show no change on further employment. HgCl₂ (0.02%) and HCl (0.3%) are also strong positive catalysts, while CaBr₂, Al₂O₃, and traces of H₂O are inert. The small amt. of air which the (a) can absorb exerts a positive catalytic influence; this may account for the earlier observation that the increase in surface in proportion to the mass of (a) increases the velocity of rearrangement. M., S. and V. believe the above facts show conclusively that the rearrangement occurs directly through intramol. shifting of the atoms and not by dissociation into isobutene and HCl and subsequent addition (Brunel, C. A. 6, 344, and earlier workers). That the rearrangement takes place more readily in the liquid than in the gaseous state may be due to the fact that in the liquid state the change occurs not in sep. mols. but in aggregates of them ("polymols.") whose total energy may be greater than that of the gaseous mols. CHAS. A. ROUILLER.

Certain derivatives of tetrabromo-*o*-quinone. C. LORING JACKSON AND SYDNEY A. BIGGS. *J. Am. Chem. Soc.* 38, 676-85 (1916).—From 10 g. tetrabromo-*o*-quinone in 60 cc. C₆H₆ shaken with 28 g. K₂SO₄ in 100 cc. H₂O at 10°, quickly filtered and allowed to stand overnight is obtained *dipotassium dibromopyrocatecholdisulfonate* (a), C₆Br₂(OH)₂(SO₃K)₂, needles, gives with Pb(OAc)₂ in H₂O a white ppt., reduces AgNO₃ on standing, gives a deep blue color with FeCl₃, turns dark brown with hot KOH and after 2 hrs. boiling is converted into K euthiochronate. *Barium salt*, from the Pb salt decompd. with dil. H₂SO₄ and shaken with BaCO₃, crystals with 3H₂O. *Calcium salt*, crystals with 4 H₂O. The free acid could not be isolated; the soln. obtained from the Pb salt treated with insufficient H₂SO₄ turned red even when evapd. at room temp. either spontaneously or with a blast of air; H₂S, even on long standing, decompd. the Pb salt only slightly. When 5 g. of the powdered (a), in a dish cooled with ice, is moistened with concd. HNO₃, a red color is produced; after letting stand in ice until the mass is thick and pasty it is ground with a pestle and as soon as red fumes begin to be evolved copiously the reaction is stopped by adding alc. and the mass is washed with alc. There is thus obtained what J. and B. believe to be *dipotassium dibromo-*o*-quinonedisulfonate* (b), contaminated with KNO₃ which could not be removed, as H₂O is the only solvent for the compd. but decomps. it even in the cold. Most of the 5 g. of (a) dissolves in 5 cc. cold H₂O and on standing overnight deposits 0.8 g. tri-K euthiochronate; 0.7 g. more is obtained on evapg. to 2.5 cc. Allowed to stand 6 months with MeOH, EtOH and PhCH₂OH, only in the case of MeOH did (a) form a white crust on its surface; this may have been the α -addition product sought (cf. *Am. Chem. J.* 31, 89 (1904)) but not enough was obtained for identification. In the hope of obtaining (b) free from KNO₃, (a) was oxidized electrolytically, but although (b) was formed, as shown by the red color of the soln., by the time the (a) was completely oxidized the (b) had also been destroyed, and a small amt. of CBr₃COCHBr₃ was formed (0.15-0.3 g. from 5 g. (a)). In the prepn. of (a) there is also formed a minute amt. of a substance sepg. in plates, forming an insol. Ba salt and giving no color with FeCl₃ or HNO₃. If the reaction is carried out at 50° instead of in the cold, it becomes the

chief product (35 g. from 50 g. tetrabromo-*o*-quinone). (For a time, although the conditions were apparently identical, this compd. could not be obtained by the methods which were formerly successful, but later on it again became possible to obtain it at will.) After drying at 130° (whereby it loses 5 H₂O) its compn. corresponds to C₄(SO₃K)₂O₂H₂ (or some multiple of this), which would make it the *o*-thiocronate with 1 mol. H₂O. It is white, however, while the *p*-thiocronate is yellow and *o*-quinones are in general more highly colored than the *p*-compds., and moreover it can be boiled without change with concd. KOH, is not attacked by HCl below 150° and does not reduce Ag solns.; these properties agree with what would be expected of the *α*-water

addition compound $\left[\begin{array}{c} \text{KO}_2\text{SC}:\text{C}(\text{SO}_2\text{K})\cdot\text{C}(\text{OH})\text{---} \\ | \qquad \qquad | \\ \text{KO}_2\text{SC}:\text{C}(\text{SO}_2\text{K})\cdot\text{C}(\text{SO}_2\text{K})\text{OH} \end{array} \right]_2\text{O}$, with 1 mol. H₂O. Un-

like PhNH₂, *sec*-amines did not give well-defined derivs. with tetrabromo-*o*-quinone, PhNHMe yielding only a tar, while NHMe₂ yielded black crystals, decomp. 115–25°, probably of the compn. C₄Br₄O₂(NMe₂)₂, decomp. in soln. with formation of a red product and evolution of NHMe₂, and on standing dry *in vacuo* form a tar. Similar, somewhat less stable and less sol. crystals are obtained from tetrachloro-*o*-quinone.

L. W. RIGGS.

Influence of certain substances on the activity of invertase. EDWARD G. GRIFFIN AND J. M. NELSON. *J. Am. Chem. Soc.* 38, 722-30(1916).—The inhibiting influence of glass beads on the activity of invertase is probably due to the soly. of the glass and the consequent decrease in the H-ion concn., rather than to the surface of the beads, as claimed by Beard and Cramer (*C. A.* 9, 3068; *Nature* 95, 561(1915)); in expts. in Non-sol bottles containing 0, 25, 50 and 100 g. glass beads, pH was found to be 5.9, 6.5, 7.3 and 8.5 and the change in rotation produced in 24 hrs. 0.34°, 0.11°, 0.06° and 0.02°, while in solns. in which the H-ion concn. was kept const. by means of a buffer soln. glass beads had no effect at 20° or 37°. The supposed inhibiting effects of serum, egg albumen and charcoal (Erikson, *C. A.* 5, 3291) are also due to changes in the H-ion concn. Large amts. of charcoal and Al(OH)₃ will absorb invertase (cf. Michaelis and Ehrenreich, *C. A.* 3, 920), but in small amts. they seem to have no influence on the activity of the enzyme.

CHAS. A. ROULLER.

Further researches on pure pepsin. W. E. RINGER. *Proc. Akad. Wetenschappen* 18, 738-51(1915); cf. *C. A.* 10, 482.—Pure pepsin was prepd. by Pekelharing's method from the gastric juice of a dog. By prolonged dialyzation, precipitation by (NH₄)₂SO₄ dissolving in H₂C₂O₄ and again dialyzing for a long time, R. succeeded in obtaining a Cl-free pepsin. The Cl present in common pepsin is ascribed to HCl held back, combined or adsorbed. This pepsin has no isoelectric point and in acid soln. appears to be anodal. Pepsin binds albumoses and proteins but not amino acids. Since the pepsin combines chiefly with H ions in HCl soln., pepsin must be a compd. of a highly complicated protein and the enzyme. With continual addition of acid to protein soln. the swelling is made to pass through a max. The optimum of digestion lies at the reaction which concurs with a max. swelling. A study was made with HCl, H₂CO₃, lactic acid, citric acid, H₃PO₄ and H₂SO₄. In concd. AcOH soln., pepsin is inactive. Max. swelling does not occur at the same H ion concn. with different acids, but if the acid is highly hydrophilous, it will prevail even in slight concn. Salts with strongly hydrophilous ions retard the action of pepsin; Na salts in lactic acid soln. at 15° showed citrate < acetate < Cl < ClO₄ < NO₃ < CNS < SO₄. The retardation of pepsin activity and influence upon swelling proceed collaterally. The max. swelling of dissolved protein shifts according to the formation of other substances.

R. L. S.

Activity of enzymes in emulsin other than β -glucosidase, in the biochemical synthesis of alcohol β -glucosides. E. BOURQUELOT AND A. AUBRY. *J. pharm. chim.* 12, 305-14(1915).—In emulsin, the enzymes β -glucosidase, lactase, β -galactosidase, gentiobiase (*C. A.* 8, 3063) and cellulase (*C. A.* 4, 1870, 1994) have thus far been more or less well defined. In an alc. soln. of dextrose only the 1st, 4th and 5th of these enzymes can act simultaneously, forming, resp., β -glucose, β -galactobiose and β -cellobiose. As the amt. of glucoside formed is

of the bioses increases with concn. of dextrose, *i. e.*, with decreasing H_2O , the influence of increasing amts. of H_2O on the yield of glucoside must be detd. Preliminary expts. are recorded to show the downward march of optical rotation to equil. when emulsin (1 g.) is added to 8 aq. solns. of dextrose in amts. decreasing from 70 to 10 g. per 100 cc. at ordinary temp. For dextrose, $[\alpha]_D$ is $+52.5^\circ$, for gentiobiose $+10.2^\circ$, cellobiose $+34^\circ$. The results tabulated and plotted in a curve show that opt. rotation diminishes both at low and at high concns., by much greater amts. when concn. is high than when low; but equil. is reached far more slowly in high than in low concns. (70 days in 70 g. per 100 cc., 14 days in 10 g. per 100). From the loss of opt. rotation, the hypothetical amts. of gentiobiose formed are calcd. for each soln.; of cellobiose only for the soln. of 70 g. in 100. With solns. 30 g. and 50 g. in 100, isolation of the bioses was attempted after equil. by fermenting off dextrose and detg. the opt. rotation, reduction and dry wt. of residue. The results point to the formation of one or several other unknown polyoses. It is finally shown that the above diminution of opt. rotation in samples 10 g. and 15 g. per 100 is not in the least affected by the presence of a neutral liquid, *e. g.*, Me_2CO . Thus the activity of hexobiases is not influenced by $EtOH$, and is independent of that of β -glucosidase except that the latter may take away dextrose for its own synthetic action. In 1 expt. with glycol, excess of dextrose and emulsin, gentiobiose crystallized first. Cf. *C. A.* 10, 771. S. WALDBOTT.

Uric acid in the organism. M. ISRAELSON. *Pharmazevlizeski J.* 19, 189; *J. pharm. chim.* 12, 363-5 (1915).—Distinction is made between *exogenous* uric acid, due to decompn. of nitrogenous food, and *endogenous*, due to the breakdown of the nucleoproteins of the cells, the latter being the real cause of uricemia. S. WALDBOTT.

The influence of temperature and poisons upon enzyme action, fermentation and growth. OTTO RAHN. Univ. Ill. *Biochem. Z.* 72, 351-77 (1916).—The temperature coeff. of growth is not const. but gradually decreases to zero with increase of temp. Enzymes in soln. are unstable. The velocity of decompn. has a very high temp. coeff. The decompn. is not caused by the activity of the enzyme, for the enzyme is really protected by the substrate. The action of the enzyme upon the substrate has a normal temp. coefficient. The same amt. of enzyme causes, at higher temps., a more rapid change; yet the reaction velocity is not const. for the amt. of enzyme decreases. With increasing temp. the 2 processes oppose one another; the decompn. of enzyme is more rapid than the increased enzyme action. Thus the reaction velocity gradually becomes zero. There is no const. "optimal temp." of enzyme action; the optimal temp. decreases with the time and approaches asymptotically the lowest temp. Enzyme reactions are incomplete processes. At low temps. they can be nearly complete. The end point of enzymic reactions decreases with increasing temp. The temp. coeff. of enzyme destruction must be larger than that of enzyme action. The fermentation enzymes are decompd. inside as well as outside of the cell. The living cell forms, under normal conditions, new enzyme in amt. sufficient to replace the loss by decompn. The normal living cell therefore works with a const. amt. of enzyme and thus the fermentation velocity is const. Since the temp. coeff. is very great for enzyme decompn., there comes a point with increasing temp. at which the enzyme formation cannot replace the destruction. Because of this the fermentation velocity gradually becomes zero. The higher the temp. the more quickly this occurs. In fermentation by living cells there is a true const. optimal temp., which is the highest temp. at which the processes of enzyme formation and decompn. are equal. The same considerations hold for growth. We suppose a growth-producing agent, which is unstable and is replaced by the cells. Therefore there is a const. optimal temp. of growth. Poisons influence enzyme action as well as decompn., the latter more than the former. The result is that the strongest enzyme activity shifts, with the time, from the largest concn. of

poison to the smallest. With fermentation, using slight stimulations, there can be a permanent acceleration without injury to the organism. The same is true for growth.

C. J. West.

Retarding influence of the light from a quartz lamp upon coagulation of the blood. WALTHER HAUSMANN AND ERNST MAYERHOFFER. Vienna. *Biochem. Z.* 72, 379-83 (1916).—Plasma, prepd. from blood treated with concd. NaCl soln., when exposed to light from the quartz mercury lamp, is not coagulated by the further addition of distd. H₂O, while the untreated control coagulates a few min. after such addition. Through the light treatment one is able noticeably to retard the coagulation of NaCl plasma by H₂O. The plasma prepd. from blood by the addition of K oxalate coagulates much more slowly after the addition of CaCl₂ when subjected to the action of light from the quartz mercury light. From this follows the necessity of carefully adjusting the action of ultraviolet light upon patients.

C. J. West.

Enzymes. X. Enzymic synthesis of disaccharides. WALTHER LÖB. Berlin. *Biochem. Z.* 72, 392-415 (1916).—600 g. sugar beet gave 260 cc. juice, with a rotation of 0.28° (10 cc. dild. to 1 l.) corresponding to a sucrose content of 21.1%. The juice contains an enzyme which decomposes small amts. of urea, a catalase, peroxidase and an invertase. This invertase is not capable of synthesizing disaccharides. Similarly, the invertases of yeast, the pancreas and the kephir grain are not capable of synthesizing disaccharides from hexoses.

C. J. West.

Micella are not necessary for the explanation of uncomplicated swelling. J. R. KATZ. Univ. Amsterdam. *Z. physiol. Chem.* 96, 255-87 (1916).—Earlier work has shown that in the case of swelling of crystals, the phenomenon can be explained very well without the use of the supposition of micella. The simple theory that swelling depends upon the formation of a solid soln. of water in the *quellbar* compds. is sufficient to explain all observed facts. This theory is now extended to amorphous substances. The principal difficulty heretofore has been the secondary complications. To avoid these one must observe the following precautions: The compds. investigated must be homogeneous, must not be a mixt. of several substances (as are most proteins and polysaccharides), must not change color upon addition or loss of H₂O, must not be capable of irreversible change, or must be investigated after these changes have occurred, must not have a porous structure and must not show hysteresis. The vapor tension curves of all substances investigated (casein, cellulose, Ca₃(PO₄)₂, gum arabic, peptone, serum albumin, cerebrin and gelatin) have similar forms and are the same as those found for cryst. substances. Study also was made of the heat evolved during swelling, of the contraction of vol. and of the relation of these to one another. The facts are fully covered by the theory of a solid soln. of water in the *quellbar* compds. and in the older theory *micella* can be replaced by *molecules*.

C. J. West.

Phylloerythrin. Bilipurpurin. HANS FISCHER. Univ. Munchen. *Z. physiol. Chem.* 96, 292-5 (1916).—The prepn. of Lobisch and Fischer (*Monatsh.* 1903, 159) analyzes better for C₂₈H₃₆N₄O₆ than for C₂₈H₃₄O₄N₄, the formula earlier proposed. A Cu salt was prepd. from a C₂₈H₃₄N₄-AcOH soln., which analyzed for C₂₈H₃₄N₄CuO₄ thus indicating the presence of 0.5 mol. C₂₈H₃₄N₄. While this may be isolated from the feces of sheep the yield is so small that the work was discontinued. During the course of the work F. isolated a yellow pigment, C₂₈H₃₄O₂, glistening plates, m. 192-3°.

C. J. West.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

A further study of the diagnostic value of the colloidal gold reaction, together with a method for the preparation of the reagent. S. R. MILLER, N. D. BRUSH, J. S. HAMMERS AND L. D. FELTON. Johns Hopkins Hosp. *Bull. Johns Hopkins Hosp.* 26,

391-406(1915).—Great care and minute attention to detail is necessary in the prepn. of colloidal Au solns. which will be sufficiently sensitive for use in colloidal Au reactions with spinal fluids. Reference must be made to the original article for the technic of the method and for the detailed record of the examn. of 300 spinal fluids. The reaction has given the most consistent and valuable results in cases of general paresis. The sources of error are few and easily recognized and the reaction requires a minimal amt. of fluid and a technic of extreme simplicity but its entire value is dependent upon the use of a reagent suitably prepared and standardized. A. P. LOTHROP.

A colorimetric method for the determination of the hydrogen ion concentration of biological fluids, with special reference to the adjustment of bacteriological culture media. S. H. HURWITZ, K. F. MEYER AND Z. OSTENBERG. Univ. California Med. School. *Bull. Johns Hopkins Hosp.* 27, 16-24(1916).—A method is described for the detn. of the H-ion concn. in biological fluids which is not interfered with by the turbidity of the fluid or the presence of pigments. "The medium tested serves as a background for the standard test color to which it imparts its own characteristic quality of color, thus making the color of the fluid to be tested directly comparable with the standard test solns." Phenolsulfonephthalein is used as the indicator and the comparisons are made in special tubes in a comparator, for a description of which reference must be made to the original. The method is of great value in the adjustment of the H-ion concn. of media for organisms which are most sensitive to the reaction of their culture fluids. A. P. LOTHROP.

The application of reactions employed in organic chemistry in photomicrochemical investigations. C. VAN WISSELINGH. *Folia microbiologica. Holland. Beitr. zur gesamt. Mikrobiol.* 3, Heft 3, 34 pp.(1915); *Chem. Zentr.* 1915, II, 98.—Several methods for testing for chitin are proposed. The material is first heated to 160° in a sealed tube with concd. KOH, whereby chitin is changed to chitosan. The latter gives a violet coloration with I and dil. H₂SO₄. The H₂O-sol. salts of chitosan are easily pptd. by the alkaloidal reagents. Methods for the elimination of interfering plant materials are discussed. W. A. PERLZWEIG.

The test for hydrochloric acid in medicine. Answer to O. Krummacher. JOHANNES CHRISTIANSEN. *Z. Biol.* 65, 513-5(1915).—Polemic with O. Krummacher (*C. A.* 8, 2405) concerning the use of indicators. A uniform technic is claimed to be necessary if the values obtained through the use of any indicator are to represent definite concns. of H ion. W. A. PERLZWEIG.

Exogenous precipitations in histological staining. RAPHAEL E. LIESGANG. *Z. wiss. Mikroskop.* 31, 466-71(1915).—Various staining and pptg. reagents diffuse through colloidal material at a very slow rate or do not diffuse at all. The results obtained under such conditions lead to erroneous conclusions. Pptn. may occur not in the tissue under investigation but in the surrounding fluid or only at the surface. A revision of methods is advized. W. A. PERLZWEIG.

A stain for tubercle bacilli. EMANUEL KLEIN. *N. Y. Med. J.* 103, 217-8(1916).—A mixt. of 1 part of a 3% soln. of crystal violet in EtOH and 3 parts of a 1% aq. soln. of (NH₄)₂CO₃ is applied to the smear, heated to steaming and allowed to cool. The steaming and cooling is repeated twice. The excess stain is poured off and the smear is washed in tap water and decolorized by alternate applications of 10% HNO₃ and 95% EtOH. The prepn. is counterstained for 3 min. with a soln. of Bismark brown prepd. by adding an alc. soln. of the dye to water until the color equals that of tincture of I. A. H. RAHE.

A possible source of error in colorimeter observations. J. H. LONG. *J. Am. Chem. Soc.* 38, 716-8(1916).—The prisms in Duboscq colorimeters seem to be fastened

in their brass sockets by means of a wax which is too soft and may allow the prisms to drop a little in our summer climate or if the instruments are placed near radiators, etc. That such a dropping has actually occurred has been noticed by L. in several cases. The colorimeters should be frequently checked by bringing the ends of the prisms in contact with the bottoms of the cells and noting whether or not the readings are zero.

CHAS. A. ROULLER.

The electrometrical measurement of the true reaction of the blood. JOSE MA DE CORRAL. Univ. Valladolid. *Biochem. Z.* 72, 1-25(1915).—The various methods of measuring H^+ concn. are discussed. C. uses a modified form of Hasselbalch's method. The venous blood of 12-month-old heifers, measured with a natural CO_2 tension, after being coagulated in various ways and either in the dild. or undild. states, at temps. from 14 to 20°, gives an av. value of p_H 7.59 or $[H^+] 0.26 \times 10^{-7}$. The OH^- concn. would vary according to the temp. Using the difference found by Michaelis and Davidoff (with human blood) for a temp. interval of 18 to 37.5°, the value of p_H at 37.5° for heifer blood is calcd. to be 7.59—0.21 or 7.38, corresponding to $[H^+] 0.42 \times 10^{-7}$, which agrees very well with those found by Hasselbalch and Lundsgaard. The individual variations found were very small, and were attributed to errors of measurement. Venous blood of 3 normal men, measured in its natural CO_2 tension and at about 14°, gave an av. value of p_H 7.59 or $[H^+] 0.26 \times 10^{-7}$, which agrees well with the work of Michaelis and Davidoff. Rabbit blood gave practically the same figures. Thus in 3 classes of animals investigated, the H^+ concn. of the blood is practically identical. Individual variations are so small that they must be explained as errors in the method rather than as real variations. The interesting observation of Michaelis and Davidoff that diln. of the blood with CO_2 -free 0.85% NaCl soln. does not change the H^+ concn. is confirmed.

C. J. WEST.

Determination of amino acids in the urine. IVAR BANG. Univ. Lund. *Biochem. Z.* 72, 101-3(1915).—The formol titration of amino acids in urine is facilitated by shaking the urine with blood charcoal. To prevent absorption of the amino acids 20% alcohol is added to the urine. The proteins are absorbed by the charcoal in the presence of the alc. The behavior of the albumoses is not known. C. J. WEST.

Biological test for proteinogenetic amines in organ extracts and body fluids. M. GUGGENHEIM AND WILH. LÖFFLER. Basel. *Biochem. Z.* 72, 303-24(1916).—A large number of proteinogenetic amines and related compds. was tested for their effect on the isolated guinea-pig intestine. Using 100 cc. Ringer soln. as a medium of suspension the following minimal active doses were found: β -Imidazoleethylamine 0.000025 g., *p*-hydroxyphenylethylamine 0.001 g., phenylethylamine hydrochloride 0.001 g., isoamylamine hydrochloride 0.005 g., indoleethylamine hydrochloride 0.002 g., suprarine 0.00001 g., methylguanidine nitrate 0.01 g., choline hydrobromide 0.01 g., acetylcholine hydrobromide 0.000001 g., neurine hydrobromide 0.001 g. In doses of from 0.1 to 0.01 g. the following were active: alkali salts of higher fatty acids, oxalic acid, citric acid; in doses from 0.05 to 0.01 g., indole, phenol, cresol, guaiacol, Na_2HPO_4 . The following were inactive in doses of 0.1 g.: aliphatic amino acids, silk peptone, protein solns., dihydroxyphenylalanine, histidine, tryptophan, *p*-hydroxyphenylacetic acid, homogentisic acid, methylamine, ethylamine, trimethylamine, cadaverine, putrescine, guanidine, alkali salts of the lower fatty acids, glucose and lecithin.

C. J. WEST.

New method for the separation of ethanolamine (colamine) from the products of the hydrolysis of phosphatides. H. THIERFELDER AND OTTO SCHULZE. Univ. Tübingen. *Z. physiol. Chem.* 96, 296-308(1916).—Colamine may be extd. with Et_2O if a concd. aq. soln. is treated with a little CaO to remove the last traces of H_2O ; 96-98% are recovered. Choline is not removed and may be extd. by alc. Colamine

may be identified as the picrolonate. In a sample of lecithin investigated there is, besides choline and colamine, another base, a part of whose N is amino-N.

ERNEST D. CLARK.

Improved technic for staining tubercle bacilli. D. CERQUEIRA. *Brasil medico* 29, No. 31(1915); *J. Am. Med. Assoc.* 66, 231.—The specimen is stained as usual with fuchsin, heating 1 min., decolorizing with 0.2 N HNO₃ and rinsing with running H₂O. Without drying it is then treated with tincture of I for 1 min. and rinsed, then immersed in strong NH₄OH for a few sec., rinsed with a 2 per 1000 soln. of Na₂S₂O₃ and dried slowly. The bacilli show up pale pink and the granulations bluish violet. Various advantages of this technic are enumerated.

L. W. RIGGS.

Typhus bacilli in blood of dog after inoculation in the gall bladder. LANGE AND ROOS. *Arb. kais. Gesundh.* 50, 57-95(1915).—Details are given of a large number of expts. with 66 dogs and the results collected in 11 tables. The following summary is presented: By injection of typhus bacilli into the gall bladder a very rapid distribution in the blood stream takes place so that after 1-2 min. the bacilli may be found in the blood of the ear veins. This distribution takes place directly at the puncture or its immediate neighborhood, through the capillaries of the gall bladder. By proper technical manipulation this distribution may be accelerated or retarded. Other parts of the body even though well supplied with capillaries do not permit so rapid a distribution of the bacilli. Generally 30 min. after the injection the bacilli are not found in the ear veins and are always absent after 60 min., being destroyed by the bactericidal action of the blood, and in part held by the capillaries of the inner organs. The gall appears to favor the distribution of bacilli injected into the gall bladder, but retards distribution in case of subcutaneous injection. By direct injection into the liver immediate distribution takes place. Infected animals inoculated through the gall bladder become bacilli carriers, whether the rapid distribution has taken place in the blood or not. If the gall bladder is extirpated or obliterated 6 min. after injection, the dog does not become a typhus bacilli carrier. If a typhus colony after remaining 15 min. in the animal body is removed to agar and at periods of 2-3 days transplanted from agar to agar about 15 times, even after 48 days the agglutinability of the culture persists. Typhus bacilli were found in the urine of a dog 20 min. after injection into the liver.

L. W. RIGGS.

Method of sterilizing sputum before examination. D. M. GRISWOLD. Detroit. *J. Lab. Clin. Med.* 1, 189-90(1915); *J. Am. Med. Assoc.* 66, 459.—In a series of 200 sputa examd. in the usual way and then the bottles autoclaved before sending to the dump, the following results were obtained: (1) All sputa found positive in the usual way were found positive after autoclaving. (2) Among 150 sputa found negative in the usual way, 3 showed tubercle bacilli after autoclaving. The staining characteristics were not altered.

L. W. RIGGS.

Mechanism of protection against bacterial infection. CARROLL G. BULL. Rockefeller Inst. *Proc. Nat. Acad. Sci.* 1, 545-6(1915).—The animal body is believed to rid itself of bacteria by the action of certain constituents of the blood serum (amboceptor and complement) which dissolve the bacteria (lysis), or the bacteria are englobed by white corpuscles which digest them (phagocytosis). When bacteria are introduced into and later disappear from the blood, they are not eliminated by the organs of excretion, but are destroyed by the organs themselves. The problem at issue relates to the manner of destruction. When an immune serum is introduced into the blood of a rabbit suffering from pneumococcus septicemia, an immediate agglutination of the bacteria takes place. The larger the dose of the serum, within limits, the larger

the size of the bacteria clumps that are formed. The clumps are almost immediately removed from the blood by the spleen, liver and bone marrow. If the clumps are large they cannot be ingested by phagocytes; hence they multiply and soon reinvade the blood; if small they are digested by the phagocytes; the animal dies on the one and recovers on the other hand. Hence small doses of the serum causing smaller clumps may be the more effective. No extra-phagocytic dissolution of the pneumococci seems to occur. A similar mechanism operates in rabbits inoculated with cultures of the typhoid bacillus, notwithstanding the fact that typhoid bacilli are subject to serum lysis. Certain cultures of disease-producing bacteria are not, others are, pathogenic for animals; the former when injected into the circulation of a rabbit are clumped and removed; the latter under similar conditions are not. Serum lysis has been inferred, rather than demonstrated. It has been observed in shed blood but not in the living body.

L. W. RIGGS.

Improved substitute for iodized catgut sutures. C. H. WARSON. Brooklyn. *Surg. Gynecol. Obst.* 22, No. 1(1916); *J. Am. Med. Assoc.* 66, 385.—W. claims that K_2HgI_4 in alc. soln. in a diln. of 1 to 1000 has more than 10 times the germicidal efficiency of the 1 to 100 soln. of I in alc. The impregnation of catgut sutures with K_2HgI_4 by increasing the tensile strength of the gut, offers a distinct advantage over the similar use of I. Sutures impregnated with K_2HgI_4 and placed in sealed tubes with $CHCl_3$ show no deterioration on boiling the tubes, while iodized sutures are ruined by such treatment.

L. W. RIGGS.

Cellulose digestion. W. ELLENBERGER, A. SCHEUNERT, W. GRÜMMER AND A. HOPFFE. Dresden. *Z. physiol. Chem.* 96, 236-54(1915).—There is described a new microorganism which belongs to the group of *Aspergillus* and which rapidly destroys cellulose, without the presence of any other C compd. The fungus grows upon solid or liquid media. As C sources, mannitol and cellulose were used. The mineral soln. used was: H_2O 1,000 cc., $(NH_4)_2SO_4$ 2 g., K_2HPO_4 1 g., $MgSO_4$ 0.5 g., $NaCl$ 2 g. During 50 days the fungus transformed 1.43% (2.94 mg.) N into protein. While N sources are not absolutely necessary for its existence, it grows more rapidly and forms more active spores in the above N-containing medium. The fungus is aerobic and works best at 36-44°. It is quite widely distributed (in human feces, and those of various animals, in cheese, in the stomach, cecum and colon of the horse, swine and ruminants, in straw and in the pouch and second stomach contents of ruminants, etc.). It is inactive in the presence of HCl . Alc. is a very suitable source of C for the fungus. The free enzyme of the fungus is also capable of dissolving cellulose. During 50 days 59% of 2 g. cellulose were dissolved. Among the products of soln. found after 40 days were: HNO_3 , reducing carbohydrates, substances giving the Molisch test substances colored yellow by alkali and substances giving iodoform.

D. BOTANY.

CARL L. ALSBERG.

The poisoning of livestock while feeding on plants of the sorghum group. C. K. FRANCIS. Okla. Agr. Expt. Sta., *Information Circ.* No. 38, 4 pp.(1916).—Analysis showed the presence of cyanides in sorghum in the following amts. (calcd. as KCN): Dried mature kafir, frost-bitten, 0.0240%; dried young cane, stunted and wilted, 0.0300%; fresh kafir leaves, normal plant 40 in. high, 0.0018%; fresh kafir leaves, mature, frost-bitten plant, 0.0037%; fresh Sudan grass, fall seeding, 10 in. high, 0.0035%; fresh Sudan grass, second growth, 15 in. high, 0.0042%; 17 in. high, 0.0021%; 30 in. high, 0.0042%. Stunted plants, showing the need of rain, are especially dangerous.

P. M. GIESY.

The mode of action of the oxidases. HERBERT H. BUNZELL. U. S. Dept. Agr. *J. Biol. Chem.* 24, 91-110(1916).—The inhibition of the action of plant oxidases upon

the aromatic substances usually employed to demonstrate their presence or measure their activity is due to exhaustion of the oxidase mechanism. Other influences, such as temp., shaking, inhibition due to reagents or to the products of the reaction, lack of oxidizable material or of O_2 , were shown to have very little effect. I. GREENWALD.

The relative oxidase activity of different organs of the same plant. HERBERT H. BUNZELL. U. S. Dept. Agric. *J. Biol. Chem.* 24, 103-10(1916).—The relative activity of plant exts. upon a series of chromogens may be expressed in a curve developed by plotting the value for the activity upon each of the chromogens upon a different radius of a circle. Such curves are very similar for different parts of the same species of plants but are markedly different in different species. The onion appears to possess no oxidase whatever. I. GREENWALD.

Contribution to the microchemistry of hydroxymethylanthraquinone and an anthraglucoside-splitting enzyme in rhubarb. R. WASICKY. *Ber. botan. Ges.* 33, 37-45(1915).—There are at least two enzymes in rhubarb plants, an oxidase, and an anthraglucosidase. The latter acts specifically on anthraglucoside, splitting it. In Rhea and Canaigre preparations the activity of the enzyme results in the formation of beautiful crystals, since the free anthraquinones are insol. in dilute glycerol. On amygdalin the enzyme has little or no action. In the plant its task is to split anthraglucoside, which must be regarded as a reserve substance. At the same time it probably plays an important part in the synthesis of anthraglucosides. The anthraquinones which are active in the drug are formed only in the course of the development of the plant as the result of certain preliminary steps, and here also oxidation, with the help of oxidases, plays a part. These chemical processes are not yet complete when the harvest season has been reached; they continue during the drying period. B. HOROWITZ.

Excitation of protoplasmic streaming (Protoplasmaströmung) by means of various rays. H. NOTHMANN-ZUCKERKANDL. *Ber. botan. Ges.* 33, 301-13(1915).—N.-Z. succeeded, by intensive exposure to light, in bringing about plasma-streaming in the leaves of uninjured *Elodea* sprouts. This was obtained within the region of the visible rays, as well as in the regions of the infra-red and ultra-violet. The action which excites plasma-streaming increases with the wave length of light. B. H.

Physico-chemical researches in botany. HELENE NOTHMANN-ZUCKERKANDL. *Intern. Z. Biol.* 2, 94-106(1915).—A review of the physico-chemical researches on germination, factors in swelling, metabolic processes and enzyme action.

W. A. PERLZWEIG.

Biologic action of sunlight. M. DELAROQUETTE. *Bull. acad. med.* 74, No. 45 (1915); *J. Am. Med. Assoc.* 66, 65.—The author's study of plants kept in greenhouses with colored glass have convinced him that the favorable action of sunlight on tissues is not due exclusively to colored nor even mainly to the chemical rays. Plants thrived in yellow light but not in blue light. Luminous rays are active, the yellow being most active of all. L. W. RIGGS.

Chemical changes occurring during the ripening of the wild goose plum. J. S. MCHARGUE. *J. Am. Chem. Soc.* 38, 718-22(1916).—In the last stages of maturation, the plum passes rather rapidly through 3 stages of ripening; as it approaches maturity it changes from green to slightly yellowish and at this stage is sharply acid and somewhat astringent. In the course of 2-3 days it becomes bright pink and quite juicy and sweet, very often splitting at this stage. In about 48 hours more it becomes dark red and loses some of its juiciness and sweetness. Analysis of the fruit at the 3 stages of ripening gave the following values, resp.: Acidity in cc. of 0.1 N NaOH per g. plum, 3.13, 2.69, 2.40; reducing sugar in %, 5.91, 6.45, 9.16; cane sugar in %, 0.41, 3.62, 0.37. CHAS. A. ROULLER.

Physiological observations on alkaloids, latex and oxidase in *Papaver somniferum*. R. H. TRUE AND W. W. STOCKBERGER. *Am. J. Botany* 3, 1-11 (1916).—It appears from work done on the opium poppy, *Papaver somniferum*, that the oxidase reaction is most active in the upper parts of the plant, especially in the floral structure, capsules and actively growing parts. The peroxidase reaction shows less variation in its intensity in the different parts of the plants. The intensity of the oxidase reaction roughly parallels the distribution of the latex which in itself is most active. The oxidase seems to be inactivated during the course of its action. A like exhaustion or inactivation of the supposed enzyme was seen in the case of the oxidase of the Irish potato. These observations would indicate that the oxidase reaction is not due to a catalyzing agent, therefore is not due to an enzyme. With exception of the root the intensity of the oxidase reaction runs roughly parallel with the alkaloid content. In the root, the alkaloid content is relatively higher than the intensity of the oxidase reaction. Alkaloids seem not to exist as such in the poppy plant, but appear as products of the action of the oxidases on constituents present in the latex reacting in the presence of O. The alkaloids of *Atropa belladonna* differ from those of the poppy in that they are found to exist in structures dried without contact with free O and seem to exist ready formed in the plant. J. J. SKINNER.

The availability of nutrient salts. A. G. MCCALL. *J. Am. Soc. Agron.* 8, 47-50 (1916).—The work of Shive (*C. A.* 9, 2396) on the growth of plants in a 3-salt nutrient soln. has been repeated with the salts in sand culture. In soln. cultures the best growth of wheat occurred when the 3 salts were used in the following vol.-mol. partial concns.: KH_2PO_4 0.0180 M, $\text{Ca}(\text{NO}_3)_2$ 0.0052 M, MgSO_4 0.0150 M, while the best soln. in the sand culture had vol.-mol. partial concns. of KH_2PO_4 0.0072 M, $\text{Ca}(\text{NO}_3)_2$ 0.0182 M, and MgSO_4 0.00550 M. A comparison of results of the series grown in H_2O and the other in sand culture furnishes evidence for the following conclusions: The concn. of the nonadsorbed soln. in the sand is markedly lower than that of the soln. which was added. The absorbed salts are either nonavailable or are greatly retarded in their participation in the growth process of the plant. For this particular concn. the ratio of Mg to Ca ions in the optimum nutrient soln. is materially changed by the adsorption process. J. J. SKINNER.

Determination of cell sap concentration by the freezing point method. G. J. BOUYOUKOS AND M. M. MCCOOL. *J. Am. Soc. Agron.* 8, 50 (1916).—The f. p. method for detg. the concn. of the soil soln. (*Tech. Bull.* 24, Mich. Agr. Expt. Sta.) is used in detg. cell sap concn. The lowering of the f. p. of cell sap is detd. by working with crushed plant tissue and not with extd. cell sap. The concn. of the cell sap is greater when detd. directly in the plant than when detd. in the extd. cell sap. J. J. SKINNER.

Chemico-physiological contribution. TH. BOKORNY. *Arch. ges. Physiol.* 163, 27-70 (1915).—A study is made of the utilization of various org. compds. by *spirogyra*. MeOH, as a rule, is utilized by green plants. Yeast cannot utilize it if it is the only source of C, but when used in connection with sugars, MeOH causes an increase in the dry wt. 0.05% solns. of AcH do not cause the formation of starch in *spirogyra*. 0.001% solns. of HCHO give positive results (even in the dark, after 8 days). Negative results were obtained with glyoxal, BzH, $\alpha\text{-HOC}_6\text{H}_5$, CHCl₃, acetone, and ether. EtOAc alone gave a negative result, but tained by the addition of 0.025% K_2HPO_4 to 0.05% solns. tained also with milk sugar, raffinose and galactose, but neg. with *l*-arabinose, rhamnose, erythritol, xylose, sorbitol, mu. tartaric acid, levulose, hydroquinone, pyrocatechol, resorcinol acid gave a positive result.

PHILIP B. HAWK.

NORMAL.

The influence of pituitary feeding upon growth and sexual development. An experimental study. EML. GOETSCH. Harvard Med. School. *Bull. Johns Hopkins Hosp.* 27, 29-50(1916).—Ext. of the anterior lobe of the pituitary gland, when fed to young rats, has a stimulating effect upon growth and upon sexual development and activity in both the male and female. Posterior-lobe ext. has a retarding influence but the whole-gland ext. has a stimulating effect when fed over a short period of time (25-40 days). Ovarian ext. (corpus luteum) has a stimulating effect upon the female but a retarding influence upon the male sexual development. A. P. LOTHROP.

Carbon metabolism and physio-pathological significance of the carbon of the urine. REALE. Naples. *Arch. ital. biol.* 1914, 244; *Zentr. Biochem. Biophys.* 18, 157(1915).—By distributing the urinary C into various fractions R. detected a sensitive fraction which was readily attacked by nascent O, being thereby distinguished from the other fractions (which were only oxidized by complete combustion of the urine). This labile portion of the urinary C was considerably increased in healthy individuals by ingestion of carbohydrates (bread, sugar, etc.); excretion of this portion was not influenced by fats and nitrogenous substances. Intermediate decompn. products of sugar accumulate in the urine when ingestion of carbohydrates is increased above the normal. These products are oxidized by H_2O_2 and may be accurately measured by combustion and detn. of the resulting CO_2 . H. S. PAINE.

Sodium chloride metabolism in healthy individuals. L. BORELLI AND P. GIRARDI. Turin. *Giorn. accad. med. Torino* 76, 67-83; *Zentr. Biochem. Biophys.* 18, 159-60 (1915).—A certain equil. is reached in the course of 3-4 days when the organism is subjected to an especially steady diet with any desired content of H_2O and NaCl; this equil. is never absolute but always shows greater or less variations. The organism tolerates for a long period the excretion of urine of widely varying d. The d. of the urine indicates little regarding the content of NaCl, inasmuch as the d. is not only dependent upon the latter but also upon the content of other urinary elements which are excreted with NaCl. There is a close connection between the amt. of urine, NaCl content and urinary d. The d. of the urine and its NaCl content increase when the organism reacts to high NaCl ingestion and the amt. of urine remains unchanged; when the latter increases slightly the d. remains unchanged and the NaCl content increases. When the amt. of urine shows a pronounced increase the d. decreases and the NaCl content either remains unchanged or decreases. There is a coeff. of max. NaCl excretion which corresponds to high NaCl ingestion; this coeff. varies from one individual to another and is subject to considerable variations when smaller amts. of NaCl are ingested. There is a greater or less tendency toward retention, or inversely toward hyperelimination, of NaCl according to the value of this individual coeff. High NaCl ingestion and moderate ingestion of liquids lead to slight diuresis, while high ingestion of both NaCl and H_2O is followed by retention of both substances. A single ingestion of a large amt. of H_2O does not promote NaCl excretion; the latter is, however, favored by repeated H_2O ingestion. After a diet which is deficient in Cl there is a tendency toward increased retention as compared with cases in which NaCl is present in excess (even though slight). H. S. PAINE.

Influence of diet, and especially of carbohydrates, on urine secretion in infants. A. NIEMANN. Berlin. *Jahrb. Kinderheilk.* 32, 21-45(1915); *Zentr. Biochem. Biophys.* 18, 261-2(1915).—Ingestion of carbohydrates (rye flour and lactose) was followed by a remarkable decrease in the amt. of urine secreted by infants. H. S. PAINE.

Testing of liver function in children and infants by means of levulose. ERICH SCHEDE. Giessen. *Jahrb. Kinderheilk.* 32, 45-65(1915); *Zentr. Biochem. Biophys.* 18, 269(1915).—The limit of tolerance of infants is very high for levulose, *i. e.*, about 4 g. per kg. body wt.; this tolerance diminishes with increase in age. H. S. P.

Metabolism, especially of inorganic material, during infancy. IV. Comparative studies of metabolism of wet-nurse's milk and albuminous milk with especial reference to sulfur economy. AMALIE PRISER. Berlin-Rummelsburg. *Jahrb. Kinderheilk.* 81, 437-54(1915); *Zentr. Biochem. Biophys.* 18, 154-5(1915).—Absolute N excretion in the feces was greater in the case of ingestion of wet-nurse's milk than in the case of albuminous milk nutrition; the relative value of N excretion in the feces in the latter instance was, however, scarcely $\frac{1}{2}$ that in the former case. Urinary excretion showed increased N retention in the case of albuminous milk nutrition; the retained N was probably not deposited in the form of stable albumin. Ca metabolism showed a decrease in the Ca balance in 2 instances after transition to an albuminous milk diet; these cases later became rachitic. Ca retention increased in 1 instance. An improvement of the P balance was usually observed after an albuminous milk diet; this is explained in large part by the unusual increase in N retention. No difference in the distribution of P excretion between urine and feces was observed between the 2 kinds of nutrition. SO_3 excretion in the feces was unusually high in the case of albuminous milk nutrition. Transfer of SO_3 and P_2O_5 elimination from urine to feces is regarded as a measure of protection against possible surfeiting of the organism with inorganic acids; this accounts for the relative innocuousness of albuminous milk as a const. diet.

H. S. PAINE.

Observations of the iodine reaction in the feces of infants and its clinical significance. F. STRINA. Venice. *Riv. clin. pediatr.* 12, 321; *Zentr. Biochem. Biophys.* 18, 121(1915).—The I reaction depends upon the property of various organisms to become stained by I under certain conditions. One cc. of Lugol soln. is mixed on a watch glass with a small amt. of feces according to the procedure of Rodella and after 2-3 hrs. the sediment is examd. microscopically. S. tested in this manner numerous samples of infants' feces; most of the positive results were obtained in the case of artificially nourished infants. Positive results were less numerous with infants which had received a mixed diet and least numerous of all in the case of breast-fed infants. Negative results were changed to positive and *vice versa* when the diet was changed. In general, the method may be employed for obtaining at least an approx. idea of the state of gastrointestinal function and the adaptation of the organism to various diets.

H. S. PAINE.

Physiology of the effect of climate. VI. Energy changes of school children from the laboring classes in a large city. VII. Influence of sojourn in a forest health resort on the metabolism and growth of school children. FRANZ MÜLLER. Berlin. *Veröffentl. Zentralstelle Balneol.* 2, 277-310(1915); *Zentr. Biochem. Biophys.* 18, 107(1915).—The total metabolic change (calcd. from the food ingested) of school children leading (to a great extent) an indoor life amounted to 0.3 g. N and 74 cal. per kg. per day (= 1770 cal. per sq. m. of body surface). The net metabolic change per day, after deducting losses by urine, feces and digestive work, amounted to 1445 cal. per sq. m. The metabolism of the child per kg. decreases with increasing body wt.; there is also a tendency toward decrease of metabolic change per unit of body surface. Metabolic change per sq. m. of body surface is about 7% greater in boys than in girls. Total as well as net metabolic change is greater in spring than in summer and the beginning of autumn. The energy consumption of 7-14 yr. old children increased by approx. 10% on changing from largely indoor environment in a large city to a forest health resort; it amounted to 84 cal. per kg. or 67 cal. per kg. (= 1500

cals. per sq. m. of body surface) after deduction of all losses. Metabolic change was greatest in May and lowest in September. Increase in wt. was, however, greatest in September (45 g. per day) and lowest in summer (19 g. per day). VIII. Influence of sojourn by the North Sea on the metabolism of school children of the laboring classes. C. HÄBERLIN AND FRANZ MÜLLER. *Veröffentl. Zentralstelle Balneol.* 2, 311-6(1915); *Zentr. Biochem. Biophys.* 18, 107 (1915).—H. and M. studied the metabolism of 116 children who were on a sojourn by the North Sea. The av. daily ingestion of food amounted to an equiv. of 19.192 g. N and 3707.5 cals. The net metabolic change per sq. m. of body surface was 2400-2950 cals. which is an unusually high value when compared with corresponding values for these children in the homes of their parents and during sojourn in a forest health resort. Increased consumption of heat during play is not sufficient to explain this increased metabolism; the increased demand upon the combustion processes of the youthful organism during sojourn by the North Sea is attributed to purely climatic influences.

H. S. PAINE.

Specific effects of rations on the development of swine. E. B. FORBES, *et al.* Ohio Agr. Expt. Sta., *Bull.* 283, 111-52(1915).—The results are recorded of expts. to det. the capacities of pigs to grow on equiv. amts. of proteins from diff. sources.

R. C. ROARK.

The metabolism of organic and inorganic compounds of phosphorus. E. B. FORBES, *et al.* Ohio Agr. Expt. Sta., *Tech. Bull.* 6, 3-80(1915).—As a result of expts. carried out with swine it is concluded that the amt. of P which an animal will tolerate when added to the ration in readily sol. form, is definitely limited at an amt. much less than will be acceptable in its natural relationships in foods. From the great difficulty experienced in the feeding of yeast nucleic acid and of commercial phytin as well as the related compound from wheat bran, it is concluded that the isolation of such compounds from natural products alters at least their therapeutic effects in such manner that it becomes impossible to state, from investigations of this sort, on pure compounds, what may be their nutritive values in their natural relationships in common foods. That the particular organic compounds used in this investigation (nucleic acid, phytin and glycerophosphates) have nutritive values for growing swine superior to the inorganic compounds used (orthophosphates and hypophosphites) was not shown. No fundamental differences in the nutritive values of the P compds. studied were established. Cf. C. A. 9, 1072.

R. C. ROARK.

Physiology of nutrition of farm animals, especially oxen. WILHELM KLEIN. Berlin. *Biochem. Z.* 72, 169-252(1915).

C. J. WEST.

The relation between the diet, and the nitrogen and chlorine content of the sweat. ELMER BERRY. Berlin. *Biochem. Z.* 72, 285-302(1915).—More urine is excreted during work than during rest. This was independent of the diet and the amt. of sweat. The sp. wt. of the work-urine is lower than that of the rest-urine. The work-urine is not as acid, and has a lighter color. The N excretion is nearly proportional to the time, without regard to work or rest. The rest-urine had a greater content of N, but the larger vol. excreted during work made the total N excretion the same. The excretion of Cl is greatly increased during work. The amt. of N and Cl excreted in the sweat is practically independent of the diet. From 2 to 5.5% of the N is excreted in the sweat and from 13 to 30% of the Cl.

C. J. WEST.

ABNORMAL.

Further study of some etiological factors of malocclusion. MILO HELLMAN. New York City. *Dental Cosmos* 58, 189-201(1916).—Malocclusion of the teeth is intimately related to conditions that interfere with normal breast-feeding. A close relation exists between malocclusion and certain anomalies of the denture, malformation of the enamel, anomalies in size and form of the teeth, irregularities in the shedding

of the deciduous teeth and in the eruption of the permanent teeth. These anomalies of the denture may be produced by experimental disturbances of the ductless glands. Hence the internal secretions are an exceedingly important factor in the etiology of malocclusion.

JOSEPH S. HEPBURN.

Some additional observations concerning the treatment of diabetes. CLARENCE BARTLETT. Phila. *Hahnemannian Monthly* 51, 1-11(1916).—The patient is fed a standard diet to obtain a sugar-free urine. The sugar tolerance is then detd. by feeding bread, gradually increasing the amt. until sugar again appears in the urine. The daily ration of carbohydrate is limited to 2/3 of this max. amt. Should acidosis intervene, an exclusive carbohydrate diet is given, and large doses, up to 3 or 4 ounces daily, of NaHCO_3 are administered. With unsatisfactory tolerance or acidosis, oatmeal, potato, or rice diet, or "green day" ration is used, to increase tolerance. At times, in severe cases, the limited protein diet is given. The Allen treatment is of value but is not a cure-all. Cases of glucosuria accompanying diseases of the gall-bladder and pyloric carcinoma are described.

JOSEPH S. HEPBURN.

Diet free of lipoids. SERAFINO DEZANI. Turin. *Biochim. terap. sper.* 4, 475-86(1914); *Zentr. Biochem. Biophys.* 18, 155-6(1915).—Results obtained by D. in expts. on the nutrition of mice with a diet free from lipoids are contradictory to the observations of Stepp; none of the animals in D.'s expts. died. The fatal results observed by S. in the case of mice which received a diet free of lipoids are attributed, not to the lack of ability of white mice to produce lipoids, but to the fact that the mice became weary of the diet and finally refused food, consequently dying of starvation. These animals tolerated a lipid-free diet for a long period and showed normal development when the diet was varied in a suitable manner.

H. S. PAINE.

Experimental polyneuritis, especially in fowls, in comparison with human beri-beri. R. TASAWA. *Z. exp. Path. Ther.* 17, 27-46(1915).—Polemical. T. does not regard the lack of vitamins in the diet as the direct cause of beri-beri. W. A. PERLZWEIG.

The Allen treatment in diabetes mellitus. SAMUEL H. PALEY. *N. Y. Med. J.* 103, 159-61(1916).—In 5 cases of moderately severe diabetes, treated by Allen's method, the patients were maintained in metabolic equil. and the urine kept free from sugar. In these cases, whiskey, in amts. up to 12 oz. in 48 hrs., was given in place of tea or coffee during the starvation period.

Formation of uric acid in man. J. P. CHROM. *Nord. Med. Arkiv* 48, Aft. 11, 1-19(1915); *Zentr. Biochem. Biophys.* 18, 157(1915).—In the excretion of uric acid by the organism the former becomes combined in such a manner that it is not oxidizable. This is due to the fact that certain C_6H_4 substitution products intervene in the chem. transformation and either become paired with H_2SO_4 or initiate a process similar to that involved in the formation of H_2SO_4 esters. This non-oxidizable uric acid compd may undergo cleavage owing to the action of acids in the organism; when this occurs the uric acid is oxidized. Cf. *C. A.* 9, 811.

H. S. PAINE.

Indican. ORESTE CANTELLI. Bologna. *Soc. med. chir. Bologna*, session July 9, 1914; *Zentr. Biochem. Biophys.* 18, 169-70(1915).—Expts. with dogs which had undergone section and ligation of the excretory duct of the pancreas showed that the amount of indican increases in an initial period in proportion to the degree of derangement of gastric function and then decreases to the normal value on restoration of this

function. There is not always a parallelism between decrease in indican and decrease in indole in the feces; decrease in amt. of indican is due rather to destruction of indole than to the action of HCl in inhibiting putrefaction. Excretion of indican is more pronounced in the periods between meal times than is the case immediately after ingestion of food.

H. S. PAINE.

The biology of phagocytosis. The importance of oxygen for the phagocytes. H. J. HAMBURGER. *Intern. Z. Biol.* 2, 227-44(1915).—Phagocytes kept in a fluid medium deprived of O by means of N or H lose perceptibly in their phagocytic activity. If the deprivation of O lasts for 4-5 hrs., then phagocytosis is abolished entirely. It was shown previously by Verworn and H. that cells lose their ability to utilize O under CHCl_3 narcosis. This, together with the present paper, explains the inhibition of phagocytosis by the addition of small amts. of CHCl_3 . Cf. *C. A.* 10, 775.

W. A. PERLZWEIG.

Researches on phagocytosis. H. J. HAMBURGER. Groningen. *Brit. Med J.* 1916, I, 37-41.—A study of the effects of various substances on phagocytosis. The addition of 0.005% CaCl_2 to white cells suspended in serum or NaCl soln. caused an increase of 22% in phagocytic power. Expts. involving subcutaneous implantation of capillary tubes in rabbits showed that the injection of 0.06 g. of CaCl_2 per rectum caused an increase in chemotaxis. The action of Ca seems to be specific, since neither Ba, Sr nor Mg caused ameboid movement. In leucocytes suspended in NaCl soln. CHI_3 , in a dilm. of 1:5,000,000, promoted leucocytosis. Other fat solvents (CHCl_3 , EtOH, C_6H_6) induced phagocytic action at low concns., but paralysis occurred when larger amts. were used. Small quantities of these solvents dissolve the outer layer of the cell, weaken it, and increase its plasticity. Treatment with N, CO_2 and KCN also increases phagocytosis. A comparison is drawn between the induced phagocytosis and the effect of O withdrawal as regards the excitement stage of CHCl_3 narcosis. Cf. preceding abstr.

A. H. RAHE.

Occurrence and physiological significance of fat in the muscle fibers of the normal myocardium and atrio-ventricular system: interstitial granules (mitochondria) and phospholipins in cardiac muscle. H. HAYS BULLARD. Univ. Pittsburgh. *Am. J. Anat.* 19, 1-36(1916).—The cardiac muscle fibers of mammals, both fetal and adult, normally contain a variable nutritive reserve in the form of droplets of fat. In inanition the normal visible fat of cardiac muscle is gradually decreased. When fatty foods are given, a pronounced increase is seen as soon as digestion is complete. The phospholipin (lecithin and related compds.) of cardiac muscle is found in the true interstitial granules and it is not markedly decreased in inanition nor increased when fats are given in the food. Neutral fat droplets in cardiac muscle do not arise from true interstitial granules.

C. J. WESS.

Further observations on the action of the blood serum after intravenous injection of cane sugar. F. RÖHMANN. Breslau. *Biochem. Z.* 72, 26-100(1915); cf. Kumagai, *C. A.* 8, 1306.—The effect of the intravenous injection of cane sugar into dogs is not as const. as the results of Kumagai would lead one to expect. Out of 4 dogs, 1 did not show the presence of invertin after 5, 12, 21, or 23 days. Other differences were that amylase was seldom present, and the change of levulose and dextrose as well as the formation of milk sugar was not observed with certainty. The work with rabbits indicated three classes: (1) those in which sugar injection did not produce invertin in the blood, (2) those in which invertin was present, (3) those in which invertin was present, and in addition, the blood was capable of forming galactose and milk sugar from cane sugar and levulose, and contained an amylase. This indicates the presence of 2 enzymes; one, *stereokinase*, is capable of changing *d*-fructose into *d*-galactose. The presence of galactose was confirmed by the isolation of the hydrazone with di-

phenylmethane dimethyldihydrazine, and by the oxidation with HNO_3 to mucic acid. The other enzyme, *lactase*, is capable of synthesizing lactose from *d*-galactose and *d*-glucose. The urine contains galactose and lactose after the intravenous injection of cane sugar and levulose. These were isolated as osazones. In certain cases the changes seemed to take place without the presence of the enzymes. Expts. with galactose were negative. The serum of an animal treated with cane sugar may react upon a 2nd animal in 3 ways: the ferment-containing serum, after being transferred, is, at first, nearly as active as the original serum. It then gradually decreases in activity. By the transference there may be an activation, and serum which did not seem to contain enzymes may become active. In some cases the inactive serum is not activated. A dog, after removal of the pancreas, was injected with an active serum of a dog which had received cane sugar. The blood and urine contained lactose. The importance of stereokinase is emphasized, and the possibility of such enzymes, capable of acting upon proteins and their decompn. products, discussed.

C. J. WAST.

The residual nitrogen of the blood. I. IVAR BANG. Univ. Lund. *Biochem. Z.* 72, 104-18(1915).—The normal content and physiological limits of variation of the content of amino acids, urea and "rest" N of the blood in man and animals are given in the following figures: *Residual N*, man, 19-36, mean 23 mg.; ox, 15-31, mean 24 mg.; horse, 20-23 mg.; sheep, 25 mg.; rabbit, 24-47, mean 33 mg.; swine, 19-27 mg.; dog, 34-38 mg.; cat, 24-43 mg. *Amino N*, man, 3-22, mean 12 mg.; ox, 4-19, mean 12 mg.; horse, 10-12 mg.; sheep, 9-12 mg.; rabbit, 7-23, mean 17 mg.; swine, 10-13 mg.; dog, 8-10 mg.; cat, 10-24 mg. *Urea N*, man, 6-20, mean 15 mg.; ox, 10-16, mean 12 mg.; horse, 9-12 mg.; sheep, 13-17 mg.; rabbit, 8-33, mean 16 mg.; swine, 9-17 mg.; dog, 17-27 mg.; cat, 17-20 mg. The ratio of amino acid N to urea N varies from 3.7:1 to 1:6, so that one cannot definitely know the amino acid or urea content from the "rest" N figures. Figures are also given for the partition of the "rest" N between the blood corpuscles and the plasma. In 11 of the 19 expts. the plasma and corpuscles have the same "rest" N content. In the remaining expts. the corpuscles contain more. In 16 of 19 expts. the urea N is equally divided between the corpuscles and plasma. In the other 3 the corpuscles contain somewhat more urea than the plasma. In 7 cases the corpuscles contained more amino acid N than the plasma. In 5 cases the plasma contained only a trace of amino acid N. In 10 cases the contents of the two are the same and in only 2 cases does the serum contain more amino acid N than the corpuscles. II. *Ibid* 119-28.—The "rest" N is greatly increased during starvation, the principal increase being due to the urea N; the amino acid N remains practically unchanged. The increased urea N is probably due to the small amt. of urine voided. If water is given during the starvation period, the urea N is normal. This expt. also indicates that the urea content of the blood of the same individual cannot be considered a constant, but that it will vary according to the concn. of the urine. The possible relation of this to nephritis is discussed. It is possible that the urea retention might be avoided by administration of water. The feeding of proteins produces a marked increase of the "rest" N, again consisting principally of urea N. This reaches a max. in from 6 to 9 hrs., and after 24 hrs. it is normal. An amt. of protein corresponding to 150 g. amino acid is so completely changed into urea by the liver that an increase of the amino acid content of the blood could not be detected. This is true of the dog and of man. With an ordinary diet there is no noticeable increase of blood urea or amino acid N. In rabbits no increase of blood urea was found. III. *Ibid* 129-38.—The introduction of amino acids (glycocoll) into the stomach leads, within an hour, to an increased amino acid N content of the blood. This resorption is slower than is the case with sugar. After the introduction of amino acids in starved rabbits the increase in the blood content is considerably higher (about double) than in well-

nourished animals. When 5 g. glycocholl (930 mg. N) are injected, the increase in the blood is 117 mg. or 0.52% glycocholl. During the next 24 hrs., 360 mg. glycocholl N are excreted in the urine, showing that the greater part is taken up by the liver and tissues. There is no increase in the blood urea content, which indicates that nearly $\frac{2}{3}$ of the injected glycocholl is fixed by the tissues. Similar results were obtained by the injection of alanine. Expts. with a dog showed a greater utilization of injected glycocholl than in the rabbit. The utilization in man seems to correspond more closely to that in the rabbit. IV. *Ibid* 139-45.—A study was also made of the behavior of urea in the organism. Urea is very poisonous, especially to starving animals. A few minutes after the administration of urea there is a considerable rise in the blood urea content, which increases for about an hour, reaching a max. (0.2% urea) at that time. Little difference was found between normal and fasting animals. Injections intravenously and by stomach show that a large part of the urea disappears very rapidly from the blood. This must be held by the tissues as a complex compd. and not merely as a soln. in the water of the tissues. While the large amt. of urea has disappeared from the blood after several hrs., yet there is a certain hypercarbamidemia, which, compared with the original urea content, is considerable. This indicates that the action of the kidneys is a secretion process and not a filtration. *Per os* administration of urea shows that the toxic effect is due to the NH_3 formed from the urea (5-6 mg. as compared with a normal of about 1 mg.). Similar toxic effects were observed after administration of NH_4 salts. V. *Ibid* 146-68.—*Sublimate nephritis*. Fifteen mg. sublimate, in a normal animal, produces marked retention of urea (352 mg. on the 5th day), with a corresponding decrease of the urine voided. Albuminuria was present on the 2nd and 3rd days. With fasting animals a similar result is obtained with 5 mg. sublimate. This effect is very much diminished by giving water to the animal. The sublimate has a certain threshold value, which is necessary to produce intoxication. This value may be reached by either decreasing the amt. of H_2O which passes through the kidney (starvation) or by increasing the amt. of sublimate given. *Chromate nephritis*. Different animals react very differently towards chromate. Sixty mg. produce a strong intoxication, a marked albuminuria and considerable urea retention. Here also the condition of nutrition plays an important part, probably due to the influence of the water content of the blood. *Tartrate nephritis*. Similar results were found. *Phosphorus poisoning*. P poisoning is accompanied by an increase in the amino acid N content of the blood on and after the 3rd day and a slight increase in the urea N content. The NH_3 content was 3.6 mg. per 100 cc. blood. C. J. WEST.

Expedition of Prof. Pannwitz to Teneriffe in 1910. IV. The nitrogen excretions in dry, high climates. A. DURIG, C. NEUBERG AND N. ZUNZ. *Biochem. Z.* 72, 253-84 (1915).—As compared with similar results obtained in Berlin, the excretion of N was 2.5 to 3 times as large in Teneriffe. The values for Cl were not increased. This may be due to the dry climate rather than to the high altitude.

Green coloration in human milk after feeding liver. E. I. *Biochem. Z.* 72, 378 (1916).—A green coloration of human milk is very common after feeding calf or ox livers; it disappears in about 16 hrs. This is due to the bile pigments from the liver.

Physiology of glands. XXIV. The function of the spleen. The co-ordination of the liver and spleen. LEON ASHER AND GUSTAV EBNÖTHER. *Biochem. Z.* 72, 416-55 (1916); cf. C. A. 10, 777.—In the decompn. of hemoglobin by splenic exts. there is formed an intermediate decompn. product which does not undergo the reactions of hemin; yet the hemoglobin is not so far decompd. that the Fe is in unmasked form. These results indicate that a function of the spleen seems to be to furnish a substance to the liver which serves as an activator. C. J. WEST.

Hematoporphyrin from urine and bones. O. SCHUMM. Hamburg-Eppendorf. *Z. physiol. Chem.* 96, 183-203(1915).—The hematoporphyrin isolated from the urine is spectrographically different from Nencki hematoporphyrin, and therefore probably has a different chem. constitution. The hematoporphyrin obtained from brownish red animal bones seems to be identical, spectrographically, with that isolated from the urine. The absorption bands of various samples are given. C. J. WEST.

Researches on the perfused heart. W. BURRIDGE. Oxford. *Quart. J. Med.* 9, 43-56(1915).—In every heart examd. it was found possible by appropriately employing K salts to demonstrate the presence of a certain capital stock of contractile material. No evidence of this capital stock may be given on attempted excitation by induced shocks. For brevity this capital stock is called *C*. *C* varies from heart to heart but is const. under ordinary conditions in any particular heart. Although the majority of drugs may cause great variations in spontaneous activity they do not alter the value of *C*. Two types of cardiac failure were observed in the frog. In (a) *C* was unchanged; in (b) *C* was diminished as shown by subsequent treatment with K. Digitalis can restore the amplitude of the contractions toward this original value in cases of type (a) only. Cases of type (a) result from an alteration in the relation of the heart to the Ca salts perfusing it. There are 2 subdivisions in type (a), (1) due to a decreased Ca tension in the perfusing soln. and (2) due to a change in the reactivity of the heart to the Ca in the perfusing soln., which remains normal. The conclusion is reached that the mechanism for maintaining and utilizing the cardiac reserve is as follows: The heart has a certain capital stock of contractile material, the activity of which is evoked by the Ca of the blood. Under ordinary circumstances the relation between the heart and the blood Ca is such that when the Ca evokes the activity of a certain proportion of the whole by altering the magnitude of the response of the heart to Ca a greater or less proportion of that whole is rendered active. During sympathetic stimulation a given tension of Ca can evoke the activity of a greater proportion of the whole cardiac contractile material than was the case previously. In clinical cardiac failure the response of the heart to such amts. of Ca as are present in blood is insufficient to maintain an adequate circulation. Digitalis is a drug which enables a given amt. of Ca to evoke the activity of a greater proportion of the contractile material than is the case in its absence. Cf. *C. A.* 9, 1934. JOHN T. MYERS.

The physiology of the parathyroid glands. W. F. KOCH. Detroit. *J. Lab. Clin. Med.* 1, 299-315(1916).—From the urine of parathyroidectomized dogs were isolated toxic substances which were identified as methylcyanamide and its polymer, trimethylmelamine. These produce symptoms in dogs resembling those of parathyroidectomy, as also does synthetic methylcyanamide. Hence it is concluded that this substance is formed in the animal body, and accumulates to a toxic concn. after removal of the parathyroids. H. G. W.

G. PATHOLOGY.

H. GIDEON WELLS.

The fixation of toxins by leucocytes. KOBZARENKO. *Ann. inst. Pasteur* 29, 190-211(1915).—The leucocytes of the horse possess the property of neutralizing diphtheria toxin. This is not dependent upon the physico-chem. properties of their protoplasm but on their vital activity. These leucocytes are capable neither of absorbing nor of neutralizing tetanus toxin. The leucocytes of the rabbit include 15-20% of macrophages, possessing this property, but the effect produced is not very marked.

GEO. T. CALDWELL.

The effect of antiplatelet serum on blood platelets and the experimental production of purpura hemorrhagica. R. I. LEE AND O. H. ROBERTSON. Boston. *J. Med. Res.* 33, 323-36(1916).—An antiserum for blood platelets of the guinea pig had a

strong agglutinating and lytic action on guinea-pig platelets. This reaction was obtained only in the presence of complement. Injection of antiplatelet serum into guinea pigs produced a condition typical in practically every way of the acute form of purpura hemorrhagica in man. Histological examn. of the hemorrhagic areas gave no information concerning the manner in which the hemorrhages were produced. The antiplatelet serum had no apparent local action. The serum of guinea pigs suffering from severe purpura had no effect on platelets either *in vivo* or *in vitro*.

GEO. T. CALDWELL.

Lipase studies. III. Acid production in the tissues with especial reference to uranium nephritis. C. QUINAN. *J. Med. Res.* 33, 345-76(1916); cf. *C. A.* 9, 1637. —Fresh normal tissues are acid in reaction when tested with phenolphthalein and, in weighed units, the performed acid values are const. It is suggested that a lipolytic ferment in some way plays a part in the process of spontaneous acid production as it occurs in the cellular structures. Liver, kidney and muscle tissues yield const. and characteristic values when tested with ethyl butyrate. In uranium nephritis acid production is profoundly depressed, not only in the kidneys but also in the liver and the skeletal muscles. These tissues give low values for performed acid, autolytic acid and ester-splitting activity. This reduced acidity in exptl. nephritis may be due to inhibition of intracellular ferment activity by NaCl and other substances which are retained in the body in consequence of some change in the tubular epithelium induced by the uranium nitrate. In chronic spontaneous nephritis, the performed acid values of the kidney cortex and medulla are below normal.

GEO. T. CALDWELL.

The complement-fixation reactions of the Bordet-Gengou bacillus. MIRIAM P. OLMSTREAD AND OLGA R. POVITZKY. New York. *J. Med. Res.* 33, 379-92(1916).—*B. pertussis* is related in its complement-fixation characteristic to at least 2 strains of the influenza bacillus and to at least 2 atypical pertussis strains. Immune sera of Bordet-Gengou strains have been found to cross-fix with antigens of Bordet-Gengou strains only. Immune sera of some influenza strains have cross-fixed with Bordet-Gengou as well as with influenza strains. By the use of more highly specific antigens or larger amts. of complement and hemolytic amboceptor than those ordinarily employed, a differentiation of individual strains of *B. pertussis* may be possible. To obtain an immune serum of high complement-fixing-antibody content 9 or more intraperitoneal injections of a living culture of *B. pertussis* or of *B. influenzae* are advised, as a decided rise in the antibody-content curve occurs after 9 inoculations.

GEO. T. CALDWELL.

The accumulation of anisotropic fats in the interstitial cells of the kidney. J. W. McMEANS. Pittsburgh. *J. Med. Res.* 33, 475-9(1916).—Rabbits were given cholesterol by stomach tube for periods ranging from 19 to 115 days. Fatty intimal changes were found in the aortas of 3 of the 7 animals definitely reported. In these same animals yellowish white streaks, arranged radially, marked the pyramids of the kidneys. These areas were confined to the interstitial tissues and consisted of islands of cells, apparently derived from the lining cells of the medullary capillaries. Some of these cells contained anisotropic fat.

GEO. T. CALDWELL.

Tissue reactions in experimental hypercholesterolemia. J. W. McMEANS. Pittsburgh. *J. Med. Res.* 33, 481-91(1916).—Expts. performed by feeding cholesterol and foods rich in cholesterol to rabbits are attended by definite changes within the organs of these animals. The organs are found to contain large amts. of cholesterol, free or combined. The liver and the adrenals are the most important organs in which the storage at first occurs; later the corpora lutea, spleen and endothelium of the blood vessels assist in the storage.

GEO. T. CALDWELL.

Bactericidal action of normal and infected sera upon different microbes. K. SAKIGAMI. London. *Lancet* 1916, I, 127-32.—Normal serum has a slight bactericidal action upon the staphylococcus during the first hour of exposure but after many hours its power decreases. Serum heated to 60° has no bactericidal power. Normal serum has no bactericidal action upon the streptococcus. Serum of tuberculous patients has less bactericidal action than normal serum upon the staphylococcus. Serum of persons suffering from staphylococcus infections has a little stronger action than that of tuberculous patients.

GEO. T. CALDWELL.

Mottled teeth. G. V. BLACK AND FREDERICK S. MCKAY. *Dental Cosmos* 58, 129-56(1916).—This is a dystrophy of the enamel, endemic in the Rocky Mountain region. The teeth are provided with Nasmyth's membrane, but the cementing substance is lacking between the enamel rods in the outer third or fourth of the enamel. Such teeth have a dead paper-white appearance. At times the cementing substance is replaced more or less by the dark brown coloring matter, "brownin," coloring the tooth yellow to black. The defect is more marked on the labial than on the lingual surface. Brownin in small amt. may be present in normal teeth. Brownin may be removed from mottled teeth by treatment with abs. alc. for several days, followed by gasoline for a month; the imperfect portion of the enamel may then be stained with alc. gentian violet. Dystrophies of the enamel are due to disturbed nutrition during the formation or growth of that tissue. The various dystrophies are described with reference to general appearance and histological structure. JOSEPH S. HEPBURN.

An attempt to immunize calves against tuberculosis by feeding the milk of vaccinated cows. W. L. MOSS. Buffalo. *Bull. Johns Hopkins Hosp.* 26, 241-5 (1915).—A relative degree of immunity against tuberculosis may be conferred upon calves by feeding milk of vaccinated cows. Further expts. must be made to determine whether human beings are similarly influenced.

A. P. LOTHROP.

Complement fixation in thyroid diseases. S. R. MILLER AND RUTH E. FAIRBANK. Johns Hopkins Hosp. *Bull. Johns Hopkins Hosp.* 26, 245-9(1915).—The complement fixation test of Roseo (*Policlinico* 35, 1249(1913)) is of no value as a clinical means of detg. the existence of hyperthyroid states or conditions of dysthyreosis. A. P. L.

The relation of splanchnoptosis to gastric acidity. EDGAR P. SANDROCK. Johns Hopkins Hosp. *Bull. Johns Hopkins Hosp.* 26, 262-4(1915).—S. examd. 200 verified cases of splanchnoptosis. Normal or diminished amts. of free HCl were found in 83% and of total acidity in 75% of all the cases. "In ptotic stomachs there is a general tendency toward diminished acidity; hypochlorhydria and achylia are more frequently met with than hyperchlorhydria, the ratio being about 2 to 1." In 50 cases complicated by marked atony, diminished acidity was noted in a higher % of cases. Apparently the acidity in gastropnoia is largely influenced by the amt. of associated atony. Achylia was present in 12.5% of all the cases.

A. P. LOTHROP.

The calcium factor in hemophilia. A case with calcium deficiency (*calcipriva*). ALFRED F. HESS. N. Y. *Bull. Johns Hopkins Hosp.* 26, 372-6(1915).—An atypical case is described of hemophilia, having all the symptoms of classical hemophilia, in which there was a marked deficiency in the Ca of the blood from a functional point of view. The clotting of the blood was materially hastened by the addition of a dil. CaCl₂ soln. Quant. examn. of the blood showed a deficiency in Ca and in a metabolic study a negative Ca balance was obtained; this, however, became positive on the addition of Ca salts to the diet. In a comparative metabolic study of a case of typical hemophilia the exchange of Ca was normal. H. suggests that the name *hemophilia calcipriva* be applied to this distinctive type of hemophilia in which there is Ca deficiency.

A. P. LOTHROP.

Chemical studies of the relations of oral microorganisms to dental caries. IV. A biochemical study and differentiation of oral bacteria, with special reference to dental caries. (3.) I. J. KLIGLER. Columbia Univ. *J. Allied Dental Soc.* 10, 445-58(1915); cf. *C. A.* 9, 3094.—"The organisms associated with, and predominating in, primary caries (*B. acidophilus* and *C. placoides*) ferment the common sugars, readily produce a high degree of acidity, and bring about considerable dissolution of tooth substance. On the other hand, organisms normally abundant in the mouth but not directly related to primary enamel decay, as well as those that are prominent in the later stages of caries, do not produce a high degree of acidity and induce but slight dissolution of powdered teeth." The presence of Na mucinate (0.2%) in culture media favors the development of specific oral bacteria but not of the other forms. V. Tests of some biochemical activities of oral bacteria. LOTTIE M. HULL AND JEANETTE C. MULLIKIN. *Ibid* 459-63.—Oral bacteria in general cause more active fermentation of glucose and maltose than of sucrose or lactose and in most cases a given type produces approx. the same amts. of acid from at least 3 of the 4 sugars. The highest concn. of acid is produced by *B. acidophilus*. In 0.1% solns. of salivary Na mucinate incubated with mixed saliva, both acidity and alkalinity increase during the first week followed by a decrease in acidity and a steady increase in alkalinity as putrefactive bacteria outnumber the fermentative. In several expts. the amt. of thiocyanate was apparently reduced by the action of oral bacteria but the results are not conclusive. VI. Retrospect and prospect. WILLIAM J. GIES. *Ibid* 464-74.

A. P. LOTHEROP.

Sugar content of blood, exudates and transudates. UMBERTO FEDREZZONI. Modena. *Arch. fisiol.* 13, 41-54(1915); *Zentr. Biochem. Biophys.* 18, 183(1915).—F. has detd. quantitatively the sugar content of the pleuro-peritoneal effusions of individuals suffering from various diseases and attempts to obtain from these values (in comparison with the sugar content of the blood) some criterion which will serve to distinguish exudates and transudates. By use of the Bang method for detn. of sugar, F. arrives at the following conclusions: Under normal conditions there is a definite relation between the sugar content of the blood and that of exudates and transudates; in comparison with the blood an exudate has a lower and a transudate a higher sugar content. This relation persists even after 1 or more administrations of sugar. Detn. of the sugar content of effusions has important diagnostic significance when considered in connection with detn. of sugar in the blood.

H. S. PAINE.

Antiproteolytic serum action in pregnancy, birth and child-bed and the significance of the antitrypsin method in the serological diagnostics of pregnancy. R. FRANZ. Graz. *Arch. Gynaekol.* 102, 579(1915); *Zentr. Biochem. Biophys.* 18, 189(1915).—Antiproteolytic serum action is greatly increased at the end of pregnancy as compared with the serum titer of a healthy, non-pregnant individual; this increase may be regarded as a const. symptom of pregnancy and may be utilized in diagnostics. This method has the advantage over the Abderhalden reaction of being simpler in technic. During birth and also during the dilatation period and period of expulsion the serum titer increases above that of pregnancy, but decreases during the 3rd stage of labor. The titer undergoes a further increase in affections (anemia and tuberculosis in pregnancy and fever and adnexa tumors in child-bed) which are coincident with increased albumin resorption in the organism.

H. S. PAINE.

Studies of constipation; transformation of a normal flora in vitro into a typical flora of constipation. A. DISTASO. *Centr. Bakt. Parasitenk., I Abt. Orig.* 75, 507-17 (1915); *Zentr. Biochem. Biophys.* 18, 168(1915).—The peculiar nature of constipated stools is due to putrefaction, which is connected with a gradual transformation of the intestinal flora. A butyric acid odor mingled with the odor of NH_3 was observed

when this process was imitated *in vitro* with a constipated stool. The subtilis group predominates in the stool after the completion of putrefaction. The transformation of the intestinal flora exhibits, on the whole, 3 stages. The coli forms first disappear, then the streptococci and acid-tolerant bacilli predominate and finally there ensues the stage of NH_3 production (subtilis group) in which the appropriate substances are decompd. with formation of NH_3 .
H. S. PAINE.

Intestinal putrefaction and sclerosis of the aorta. T. S. STRENHUIS. Groningen. *Folia Mikrobiol.* 3, 76(1915); *Zentr. Biochem. Biophys.* 18, 167-8(1915).—The assertion of Dratchinski (*C. A.* 6, 2643) that indole plays a part in the etiology of sclerosis of the aorta was not sustained by appropriate expts. on guinea pigs; no typical atheroma was produced in animals which were treated with indole. The assumption of Mechnikov that atheromasia is due to absorption of indole from the intestine was likewise not sustained. Dissection of a woman who had suffered for 40 yrs. from congenital hypertrophy and dilatation of the lower part of the colon with aggravated constipation (and consequent passage of aromatic compds. into the blood) failed to show any unusual hardening of the arteries; the liver was not cirrhotic and the kidneys showed only a few sclerosed vessels.
H. S. PAINE.

Phosphorus poisoning and the meiostagmin reaction. FRANCO CATTORRETTI. Turin. *Giorn. accad. med. Torino* 76, 62-6; *Zentr. Biochem. Biophys.* 18, 200(1915).—The blood serum of animals (dogs, rabbits, guinea pigs) which have been treated with P gives higher values in investigation of the meiostagmin reaction than are obtained with the same animals before treatment or with untreated animals of the same kind. These observations should be of significance in explaining the nature of meiostagmins in view of the fact that lipid substances are present in the blood in increased concn. in P poisoning.
H. S. PAINE.

Indole and its derivatives. ORESTE CANTELLI. Bologna. *Il polichin.* 1914; *Zentr. Biochem. Biophys.* 18, 169(1915).—C. discusses critically the present status of our knowledge of indole. The latter is almost exclusively a product of intestinal putrefaction and acts upon the organism as a cirrhotic poison; the greater portion of indole is destroyed in the organism and the remainder is transformed into indican. Indicanuria only possesses clinical significance in exceptional cases and can only, at best, be taken as an index of the degree of intestinal putrefaction. Only by giving due consideration to destructive and synthetic power and by repeating the tests in each separate instance is it possible to make a deduction regarding the significance of indicanuria; a persistent decrease in both effects and increased indole content of the urine indicate that the process of detoxication does not proceed to completion, inasmuch as the organs do not effect the destruction of the poisons in question to a sufficient extent.
H. S. PAINE.

Thermocalorimetric investigations in serum anaphylaxis. MARIO SEGALÉ. Genoa. *Pathologica* 5, 667-72; *Zentr. Biochem. Biophys.* 18, 196(1915).—S. studied heat radiation in anaphylaxis by detg. the body temp. as well as the total amt. of heat radiated from the animal organism. The calorimetric and thermometric curve was not appreciably modified by subcutaneous injection of a small initial dose of serum. In so far as anaphylactic re-injection was concerned it was not easy to det. heat radiation in very acute cases (intravenous re-injection). The heat radiation, as measured by the usual methods, failed to show any appreciable change when anaphylaxis had a duration of 8-13 hrs.; an increase in heat radiation was observed, however, when death by anaphylaxis occurred after a longer period. Thermogenetic lack of equilibrium, therefore, be regarded as a secondary phenomenon.
H. S. PAINE.

Cholesterol content of blood serum after administration of cholesterol in certain forms of severe anemia. COLLATINO CANTIERI. Siena. *Rassegna clin. terap. sci.*

affini Aug., 1914; *Zentr. Biochem. Biophys.*, 18, 184(1915).—C.'s expts. show that administration of therapeutic doses of cholesterol ester does not cause any considerable increase in the cholesterol content of blood serum. C. leaves undetd. the questions whether the resulting favorable therapeutic effect is due to a catalytic action on the enzymic process which takes place in the interior of the tissue and whether the administered cholesterol becomes combined so readily with the various tissues that any increase in the cholesterol content of the blood serum is impossible. H. S. PAINE.

Cholesterolemia in certain severe anemic conditions. COLLATINO CANTIERI. Siena. *Rassegna clin. terap. sci. affini*, Sept., 1914; *Zentr. Biochem. Biophys.* 18, 184(1915).—Hypocholesterolemia of considerable extent is of const. occurrence in severe anemic conditions of a toxic nature. This hypocholesterolemia has no connection with the real, underlying cause of the anemia or with the pathogenetic mechanism of the latter but is rather a direct result of the disease condition, *i. e.*, the poor general condition of the organism. Cf. C. A. 9, 1804. H. S. PAINE.

Azotemia in connection with death. D. DUMITRESCU AND ALIN POPESCU. Bucharest. *Rev. stiint. med.* Apr., 1914; *Zentr. Biochem. Biophys.* 18, 184-5(1915).—All patients (except those who suffer from kidney affections) who die after an illness of greater or less duration exhibit distinct terminal azotemia. The urea content of the blood increases in a const. manner up to the moment of death; in fact, a minimal increase was observed during the 1st few hrs. after death. The curve of urea excretion increases rapidly during the period of death agony and less rapidly during the period immediately preceding; in 1 instance there was an increase from 0.52 g. to 2.42 g. per l. at the moment of death. Persons who meet sudden death by injury do not exhibit the azotemia noted above; it appears, therefore, that rapid death does not allow the necessary time for production of terminal azotemia. H. S. PAINE.

Detection of indican, its occurrence in the feces and a peculiar manner of its formation. ORESTE CANTELLI. Bologna. *Soc. med. chir. Bologna*, session May 28, 1914; *Zentr. Biochem. Biophys.* 18, 169(1915).—C. tested the method of Obermayer, Wang and Maillard for the quant. detn. of indoxyl in the case of numerous samples of urine, previous treatment with CHCl_3 being employed. A large amt. of indican was found in the feces of an individual who suffered from obstruction of the intestine in the region of the cecum; this result was not found in the case of healthy individuals or those suffering from other diseases and C. concludes that it is indicative of intestinal obstruction. A substance with the chem. properties of indirubin was obtained in expts. under the influence of bacterial action and in expts. *in vitro*; the indoxyl which was isolated from the feces appears to be autochthonous and of bacterial origin. H. S. PAINE.

Does the detection of tryptophan and indoleacetic acid in the feces and urososein in the urine possess any particular value either in itself or in conjunction with the detection of indoxyl and indole in the urine and feces? ORESTE CANTELLI. Bologna. *Soc. med. chir. Bologna*, session June 18, 1914; *Zentr. Biochem. Biophys.* 18, 169(1915).—After numerous investigations of feces and urine with regard to the presence of the substances mentioned above, C. concludes that such tests are not sufficient to throw much light on especial disease conditions. H. S. PAINE.

Toxins of intestinal worms. D. EM. PAULIAN. *Spitalul*. No. 15/16, 1914; *Zentr. Biochem. Biophys.* 18, 194-5(1915).—Intestinal parasites produce both a local and a general effect, the latter being due to excreted toxins. Subcutaneous injections of exts. and macerations of *Taenia cucumerina*, *Ascaris*, *Oxyuris* and *Trichocephalus* in rabbits in doses of 3-15 cc. produced both local and general phenomena; among the former were necrosis and congestion and hypertrophy of the lymphatic glands, while fever, eosinophilia and congestions and hyperemia of the spleen, liver, kidneys, lungs

and brain were observed among the latter. Macerations were more toxic than alcoholic exts. or exts. prepd. with physiol. NaCl soln. Cf. C. A. 10, 780. H. S. PAINE.

Density of the blood in complete fast. D. DUMITRESCU-MANTE. Bucharest *Spitalul*. No. 21/22, 1914; *Zentr. Biochem. Biophys.* 18, 185(1915).—The H₂O content of the blood decreases in a const. manner during absolute fast and the toxicity of the blood shows a const. increase. Most of the H₂O is eliminated by the lungs and this is particularly the case during the later stages of fast when excretion by means of the urine and feces becomes negligible. The toxicity of the blood is demonstrated by the changes in the kidney tissue, i. e., the concd. poisons of the blood attack the tissue of this organ to a pronounced extent during their passage through the renal filter. Azotemia, which appears toward the approach of death in fasting animals, is a further consequence of the concn. of the blood. H. S. PAINE.

Chemical etiology of cancer according to Nowell. ERNST FRAENKEL AND WASSA KLEIN. Heidelberg. *Z. Krebsforsch.* 15, 76(1915); *Zentr. Biochem. Biophys.* 18, 152-3(1915).—The substance obtained by Nowell from carcinoma tissue (and placed at the disposal of F. and K.) was found to consist largely of Zn sarcolactate with slight admixt. of org. substance. The substance obtained by Nowell from sarcoma tissue consisted largely of Zn phosphate with slight admixt. of Zn sarcolactate. The presence of these salts is explained by the technic employed. It was possible, by subcutaneous incorporation at the base of the ear of rabbits, to produce granulation tumors with carcinoma substance as well as with Zn lactate and other Zn salts. Further inoculation of these tumors in rabbits and mice was not successful. No granulation tumor was produced in mice by subcutaneous incorporation of Zn salts. H. S. PAINE.

On the occurrence of protective enzymes in various conditions. Testing of their activity by means of the micro-Kjeldahl method. B. T. KABANOW. *Fermentforschung* 1, 206-9(1915).—A corroboration of previous findings in cases of pregnancy where dialysis and the ninhydrin reaction were used. W. A. PERLZWEIG.

Differential diagnosis between paranoia and dementia paranoides on the basis of the Abderhalden dialysis method. E. WEGENER. *Fermentforschung* 1, 233-53 (1915).—The sera of 14 patients suffering from dementia paranoides were found to digest either sex gland and brain tissues, or thyroid and brain tissues, while the sera from paranoid chronica patients never digested brain tissue, and very seldom digested tissues of gland of internal secretions, indicating that in the latter disease the brain is not affected, as it is in the former. W. A. PERLZWEIG.

Practical and theoretical considerations of the (Abderhalden) dialysis methods. V. KAFKA. *Fermentforschung* 1, 254-68(1915).—No protective enzymes were found in the sera of 32 physically and mentally normal individuals, towards the following tissues: brain, brain-cortex, testes, ovary, thyroid and parathyroid. The previous findings of Abderhalden and of Fauser regarding the degeneration of sex glands in dementia praecox are confirmed. Regarding the nature of the protective enzymes, K. doubts whether the proteolytic enzymes indicated by the dialysis method are comparable to amboceptors, since he could not demonstrate the complement-fixation phenomenon. W. A. PERLZWEIG.

Serological studies in pulmonary tuberculosis, employing the optical method. H. E. LAMPÉ AND J. CNOFF. *Fermentforschung* 1, 269-310(1915).—The previous dialysis studies of Lampé (cf. C. A. 8, 168) on tubercular serum are confirmed by the use of the optical method. The serum of non-tubercular persons did not digest tubercle bacillus protein or lung tissue. In positive cases of lung tuberculosis such digestion did occur. The most intensive development of protective enzymes was found in well nourished persons with stages of tuberculosis not too far advanced. The quantitative

possibilities of the optical method are pointed out as regards their prognostic and diagnostic values. W. A. PERLZWEIG.

The Abderhalden reaction in Parkinson's disease. C. J. PARHON AND MARIE PARHON. *Fermentforschung* 1, 311-4(1915).—In the majority of cases of paralysis agitans, positive dialysis reactions were obtained with thyroid, parathyroid and hypophysis. The use of adrenals yielded positive results only rarely, while the reaction was wholly negative with sex-glands. Frequently the reaction was positive with muscle and nerve tissues. On the basis of these findings it is suggested that the disease is brought about by changes in the thyroids, parathyroids, and hypophysis. This is accompanied by degeneration of nerve and muscle tissue. If the disease appears suddenly a latent glandular change may be suspected. W. A. PERLZWEIG.

Thermolability of complements. T. MADSEN AND T. WATABIKI. *Oversigt kgl. Danske Videnskab. Forhandling* 1915, 125-59; *Chem. Zentr.* 1915, II, 844.—Complement inactivation in the sera of swine, horse and guinea pig at temps. of 14-56° may be expressed by the law of monomolecular reactions. Between 40 and 56° the dependence of reaction velocity upon temp. follows the van't Hoff-Arrhenius law, and the temp. coefficient (μ) varies between 60,000 and 110,000. At 37° or lower the velocity of the reaction deviates from the above law. The albumin and globulin fractions (end- and middle pieces) behave similarly. It is immaterial whether the amboceptors of the employed serum are used, or they are absorbed by red blood cells and liberated by immune rabbit serum. W. A. PERLZWEIG.

Thermolability of amboceptors. T. MADSEN AND T. WATABIKI. *Oversigt kgl. Danske Videnskab. Forhandling* 1915, 161-70; *Chem. Zentr.* 1915, II, 844; cf. preceding abstract.—Amboceptors obtained by the action of swine serum on sheep blood cells and amboceptors obtained through the immunization of rabbits towards sheep blood cells or guinea-pig kidney tissue were studied. Since the complement is destroyed at temps. much lower than the experimental temp., fresh serum was added when testing. Guinea-pig serum was used for this purpose. Between 60 and 80° the rate of inactivation followed the law of monomolecular reactions. The relation between temp. and reaction velocity followed the van't Hoff-Arrhenius law; while the temp. coeff. varied between 106,000 and 16,000, corresponding to an increase in the rate of inactivation of 1.57 to 1.07 for 1°. W. A. PERLZWEIG.

Contributions to the pathology of edema. I. L. HESS AND H. MÜLLER. *Z. exp. Path. Ther.* 17, 59-71(1915).—Subcutaneous injections of aromatic *m*-diamines produced edema through the alteration of capillaries. II. *Ibid* 17, 72-3.—Subcutaneous administration of pyrocin and *m*-tolylhydrazine produced edema. W. A. P.

The chemistry of kidney-stones. MAX KAHN. *Z. exp. Path. Ther.* 17, 88-97 (1915).—The majority of calculi consist of CaC_2O_4 . While uric acid and urates are found in small quantities in all stones, calculi consisting chiefly of uric acid or urates are very rare. Shape, color and density of a stone cannot be taken as criteria of its chem. compn. Gout tophi do not always consist of uric acid or urates. W. A. P.

A study of the diagnostic value of the Russo reaction. MAX KAHN AND LAWRENCE WECHSLER. *Med. Record* 89, 106-7(1916); cf. Kahn, *Biochem. Bull.* 1913.—Comparison with tinted glass is made for the purpose of determining the color characteristic of this reaction. A table drawn from the examination of 758 urines from as many patients is given, showing the results of the Russo, diazo and Weiss tests in typhoid and other diseases. Both the Russo and diazo tests are of diagnostic value, but the Weiss test seems of doubtful worth. A. H. RAHE.

Serological method in detection of trypanosomiasis in horse disease. R. OFFERMANN. *Arch. kais. Gesundh.* 50, 1-30(1915).—The results of complement-fixation and

agglutinin tests with 12 rabbits are given in 25 tables. O. summarizes as follows: Serum from healthy rabbits frequently has an antihemolytic action, which is decidedly variable in strength. The use of 0.01 cc. or less of normal rabbit serum failed to produce the antihemolysis. A test for infection is made by using the rabbit serum in complement-fixation expts. Agglutinins, which produce agglutination of trypanosomes of horse disease, are not found in normal rabbit serum. In the serum of rabbits infected with trypanosomes of horse disease, complement-fixation antibodies and agglutinins were present. Complement-fixation amboceptors appeared on the average 9 days after inoculation and 4-9 days after the appearance of trypanosomes in the blood, while agglutinins appeared on the average 13 days after inoculation and 4-22 days after the trypanosomes in the blood. The appearance of the antibody was transient and varied in activity according to the individual and course of disease, frequently diminishing as the disease progressed but increasing toward the end. No regularity in these variations was observed, but in no case was the blood entirely free of antibody. By sterile preservation of the serum the antibody retains its activity for many months. For agglutination fresh trypanosome material must be used. The antigens of trypanosomes when preserved in the ice box retain their activity for weeks. As complement fixation gives better results than agglutination it is to be preferred as a diagnostic aid.

L. W. RIGGS.

Products of putrefaction in the intestines as a factor in blood diseases. O. CANTELLI. *Riforma medica* 31, Nos. 45-8(1915); *J. Am. Med. Assoc.* 66, 391.—C.'s expts. on rabbits confirmed the assumption that indole has a pronounced destructive action on the blood, the findings under its influence being similar to those in the blood with gastric cancer. Just as certain poisons, such as Pb, are able to modify the blood until the blood picture suggests pernicious anemia, the products of putrefaction in the intestines are able to do the same in rabbits, and probably also under certain conditions in man.

L. W. RIGGS.

Clinical determination of renal function by an index of urea excretion. F. C. MCLEAN. New York. *J. Am. Med. Assoc.* 66, 415-20(1916).—Ambard's laws are discussed and over 20 references to recent literature given. The author's formula is $I = (D\sqrt{C} \times 8.96)/(Wt \times Ur^2)$, in which I is the index of urea excretion, D is the number of g. of urea excreted in 24 hrs., C is the number of g. of urea per liter of urine, Ur is the number of g. of urea per liter of blood, and Wt is the body wt. of the individual in kg. The rate of excretion is not actually detd. for 24 hrs. but usually for 72 min., the important point being to det. the rate of excretion at the time of observation. The essential points in an observation are (1) collection of urine over a carefully timed period, (2) collection of blood near the middle of that period, and (3) accurate detns. of the urea content of the samples of blood and urine. The usual routine is as follows: The patient drinks 150-200 cc. of water and 30 min. later voids urine in order to start with the bladder empty, catheterization being employed if necessary. The time of voiding is recorded to within 1 min. About 36 min. later 7-10 cc. of blood are withdrawn from an arm vein into a dry tube containing K oxalate or citrate to prevent clotting. At the end of 72 min. from the first voiding, the bladder is again emptied and the urine measured to within 1 cc. and used for analysis, or one-half used for analysis and the other half for a simultaneous phenolsulfonephthalein test. The patient takes no food or water during this period; otherwise no restrictions are necessary. The 72 min. period is merely for convenience; 36, 60 or 120 min. periods may be used. Analyses should be by the most accurate modern methods, the urease method of Van Slyke and Cullen (cf. *C. A.* 8, 2496) being specially recommended. Three detns. are necessary: blood urea, urine urea and urine NH_3 , the latter as a correction to the urea detn. for preformed NH_3 detd. in the urea method. Duplicate detns. on blood are

recommended. Illustrations are given for a rapid method of computing the index by aid of the slide rule. Among the findings it may be mentioned that the index is independent of the N intake, and that the actual blood urea figure may be very misleading, if taken by itself, as an indication of the ability of the kidneys to eliminate N. An increased level of urea in the blood is purely compensatory, and is not due to a lack of ability on the part of the kidney to excrete the larger amts. of urea being formed in the body.

L. W. RIGGS.

Pellagra: causation and a method of prevention. JOSEPH GOLDBERGER. Washington. *J. Am. Med. Assoc.* 66, 471-6(1916).—The results of studies with a "pellagra squad" of 11 men, furnish additional evidence that pellagra is caused by deficiencies in the diet, and in this respect resembles beriberi. While a definite conclusion as to the intimate mechanism involved in bringing about or preventing the disease, cannot be drawn from the data available, the dietary deficiency is capable of prevention or correction by the inclusion in the diet of suitable proportions of fresh animal and leguminous protein foods.

L. W. RIGGS.

Effects of phlorizin on tumors in animals. F. C. WOOD AND E. H. McLEAN. Columbia Univ. *J. Cancer Res.* 1, 48-70(1916).—Administration of small doses of phlorizin to rats with either spontaneous tumors or inoculated sarcoma, did not cause absorption of the tumors.

H. G. W.

Chemotherapeutic experiments on rat tumors. RICHARD WEIL. Cornell Univ. Med. School. *J. Cancer Res.* 1, 95-106(1916).—Analyses of tumor rats after injection of NaI showed the blood to contain the highest amts. of I, after that the tumors and the liver; but if the tumors were small and not necrotic they contained little I. After injection of dyes of the diazo group the necrotic areas of tumors present an intense coloration, and often the liver is stained, but not the other tissues. The staining of necrotic areas in tumors is not due solely to the death of the cells, as areas of pulmonary caseation in the same rats are not colored. The location of colloidal dyes in necrotic tissues is not a simple physical phenomenon; the diffusibility of the dyes through membranes, the elec. charge, the chem. reaction and the chem. compn. of both colloids influence the results. A series of new synthetic compds. analogous to Congo red were injected into tumor rats, without definite therapeutic effect.

H. G. W.

Gonococcus complement fixation: A new lipid antigen. CARL C. WARDEN, Ann Arbor, Mich., AND LOUIS E. SCHMIDT, Chicago. *J. Lab. Clin. Med.* 1, 333-47 (1916).—An alc. soln. of the fats of the gonococcus serves as antigen in the gonococcus complement-fixation test, and is superior for the purpose to the watery antigen of commerce. Positive reactions are always of value. Repeated negative reactions in the absence of clinical signs are of great value. A single negative reaction has no significance whatever. While the sera of normal persons have been found wholly negative, and while it is admitted that positive reactions are largely confined to cases where the gonococcus is, or has recently been, present, nevertheless the evidence as a whole is that a positive reaction indicates the presence in the serum of some substance which reacts with the antigen (antibody?) to produce fixation of complement, and not necessarily the presence of a focus of gonococcus in the body.

H. G. W.

Influence of diet and iodides on the hyperplasia of the thyroid gland of opossums in captivity. R. R. BENSLY. Univ. Chicago. *Am. J. Anat.* 19, 57-65(1916).—The spontaneous hyperplasia observed in the thyroid gland of the opossum under lab. conditions can be produced and controlled by diet alone; given the conditions dietary and otherwise which produce an active hyperplasia, iodine will not inhibit the reaction. At all periods of the hyperplasia and to an extent which is proportional inversely to the rate of hyperplasia, iodides will cause storage of intrafollicular colloids.

C. J. WESS.

Studies in blackwater fever. V. The duration of hemoglobinuria. J. W. W. STEPHENS. Univ. Liverpool. *Ann. Trop. Med.* 9, 539-42(1915); cf. *C. A.* 9, 1510.—Of 167 cases of hemoglobinuria in this disease, 45 were not more than 12 hrs. in duration, 77 not more than 1 day, and 45 were more than 2 days. C. J. WEST.

Experimental study of the relation of uremic azotemia to indicanemia and indicanuria. MAX ROSENBERG. *Arch. exp. Path. Pharm.* 79, 266-84(1916).—It is shown by expts. on dogs with exptl. kidney injury that the hyperindicanemia accompanying acute azotemia precedes an increased indicanuria, and that in this hyperindicanemia there occurs first an increased indican formation but not an increased indican retention. Only when the kidney insufficiency continues for some time is there an increased retention. The question whether the increased indican formation occurs in the intestine or in the intermediary metabolism cannot be definitely answered, but the data seem to indicate the latter source; the liver may be the seat of this formation. In artificial azotemia, produced by the addition of urea to rabbits with normal kidneys, there is a hyperindicanuria, *i. e.*, an increased indican formation. A marked hyperindicanemia is lacking here because of the non-retention of indican. From this it is possible that the azotemia stands in causative relationship to hyperindicanemia, in the sense that azotemia stimulates the increased indican formation. C. J. WEST.

Influence of tuberculosis upon the chemical composition of the animal body. KARL DRÖGE. *Arch. ges. Physiol.* 163, 266-88(1916).—Figures are given for the wt., H₂O, dry substance, fat, fat-free dry substance, ash and ash- and fat-free dry substance for 2 series of guinea pigs, normal and tubercular. Tuberculosis seems to decrease the fat content. C. J. WEST.

Enzymes which cause cleavage of the proteins of diphtheria serum. A. REISZ AND Z. BARABÁS. Budapest. *Jahrb. Kinderheilk.* 81, 334-42(1915); *Zentr. Biochem. Biophys.* 18, 189(1915).—Investigations by the Abderhalden dialysis method yielded positive results in most of the cases which were studied. H. S. PAINE.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Lesions produced by arsenicals and their bearing on the problem of specific arsenic therapy. WADE H. BROWN. Rockefeller Inst. *Bull. Johns Hopkins Hosp.* 26, 309-14(1915).—A study has been made of about 60 As compds. in which detns. have been made of their toxic limits and the essentials of their pathological action in mice, rats, guinea pigs, rabbits, and in some instances, dogs. The toxicity of compds. containing approx. the same % of As varied widely but not more so than the variety and severity of the tissue injury produced by them. Lesions were observed in the heart, blood vessels, lungs, liver, kidney and adrenals. Some degree of adrenal injury is among the most const. changes produced by all classes of arsenicals, the measure of injury being parallel with the susceptibility of a given animal species for a given compd. The expts. emphasize the importance of a thorough knowledge of the lesions produced by As compds. in the successful prosecution of the problem of specific As therapy. A. P. LOTHROP.

Sensitiveness of the skin to epinephrine and pituitrin. A. JOSEFSON. Stockholm. *Dermatol. Wochschr.* 1915, 413; *Zentr. Biochem. Biophys.* 18, 162-3(1915).—In order to ascertain whether hypersensitiveness to epinephrine exists J. examd. individuals (patients suffering from Basedow's disease and chronic nephritis, as well as pregnant individuals) with whom the existence of epinephrinemia could be assumed. The typical cutaneous test was applied with epinephrine; the reaction consisted in a remarkable pallor at the spot of inoculation. Pituitrin gave the same reaction; choline did not give the reaction, however, and J. concludes that this substance cannot be the common constricting principle of epinephrine and pituitrin. H. S. PAINE.

The attitude of the physician as a competent judge in the saponin question. R. KOBERT. *Ärztliche Sachverständigenzeitung* 1915, No. 10; *Chem. Zentr.* 1915, II, 858.—A review of the common properties of saponins, of their differences, and of their recently discovered significance for medicine. W. A. P.

Cataphoresis of drugs. I. TRAUBE AND L. BERZELLER. *Intern. Z. Biol.* 2, 107-17(1915).—The pharmacological action of drugs was found to be greatly inhibited when single drugs or mixts. were subjected to cataphoresis. This was shown by expts. on animals and by measurements of surface activity. It was also found that by this method mixtures of drugs could be sepd. into components, and impurities removed. The inhibition is believed to be due to the increase in concn. through endosmotic movements, the increase in the degree of dispersion, and probably the flocking of some antagonistically acting constituents. W. A. PERLZWEIG.

On the influence of digitalis and of a combination of digitalis and sodium salicylate upon the leucocyte count. MAUJA LÖWENSTEIN. *Z. exp. Path. Ther.* 17, 47-58 (1915).—L. failed to confirm the stimulation of leucocytosis through the action of digitalis and of digitalis + Na salicylate. W. A. PERLZWEIG.

The action of alkaline earths upon the isolated frog heart. H. KIONKA. *Z. exp. Path. Ther.* 17, 108-26(1915).—A frog heart is arrested in systole by applying 0.04% BaCl_2 soln., 0.16% CaCl_2 soln., or 0.36% SrCl_2 soln. With smaller concns. of these salts it is arrested in diastole. The entire significance of the action of the salts is not alone explained by the concns. of their resp. solns. W. A. PERLZWEIG.

Criticism of and experiments on the cumulative action of strophanthin. KAREL KLEIN. *Z. exp. Path. Ther.* 17, 127-42(1915).—The action of large doses of strophanthin becomes evident in an hour through vomiting; the action on the heart occurs after several hours, but may last for as long as a month. A typical action may be obtained through continuous administration of small doses. The intoxication occurs in such cases fairly suddenly. Reflex salivation is suggested as a dependable indicator of intoxication. Several strophanthin preps. (commercial) were employed and the various degrees of toxicity established. It appears possible to maintain the human organism under digitalis action for a long time through continuous small dosage with strophanthin, although a fatal result may ensue without any warning symptoms. W. A. PERLZWEIG.

Acquired tolerance of strophanthin, studied with reflex salivation as an indicator. KAREL KLEIN. *Z. exp. Path. Ther.* 17, 143-60(1915); cf. preceding abstract.—Cats may acquire a tolerance to strophanthin through the administration of small doses of the drug. The tolerance occurs in the circulatory and nervous systems, although there is no parallelism between the two in this process. The tolerance, however, is not constant and may easily pass into intoxication. W. A. PERLZWEIG.

• Medicinal leucocytosis. A review of the literature and some experiments on the influence of some antipyretics on leucocytes. R. P. GEHRIG. *Z. exp. Path. Ther.* 17, 161-9(1915).—Therapeutically employed doses of such antipyretics as sodium salicylate, aspirin, salol, antipyrin and salipyrin do not appear to increase the abs. leucocyte count. W. A. PERLZWEIG.

Arsenical intoxication ten months after one injection of "novarsenobenzol" (Billon). HAROLD SPENCE. *Proc. Roy. Soc. Med.* (Dermatological Sec. 6), 19, 1 (1915).—In a syphilitic with well developed secondary lesions, an intravenous injection of novarsenobenzol (a product offered as a substitute for salvarsan) gave rise to a severe dermatitis and other evidences of arsenical poisoning. Gastrointestinal symptoms were absent and no kidney insufficiency developed. A. H. RAHE.

Action of magnesium upon the body temperature. JULIUS SCHÜTZ. Univ. Vienna. *Arch. exp. Path. Pharm.* 79, 285-90(1916).—The lowering of the temp. occurs, with sleep-producing doses of Mg, at a time when the animal is only partially paretic but yet completely awake. This period of lowered temp. exceeds the duration of the narcotic and paralysis symptoms by 1 to 2 hrs. Doses which cause only paresis and not narcosis also produce lowering of the temp. This is therefore the 1st noticeable symptom of Mg action. The intensity of the temp. decrease appears to stand in a certain relation to the intensity of the succeeding paralysis symptoms. It is possible since the change is easily measured and is the 1st symptom to appear, to use it as a method for following the Mg treatment of tetanus. CaCl_2 does not retard the temp.-lowering action of Mg. In many cases the temp. lowering is so marked that the Ca-Mg action seems to be a summation of the thermal action of the two. In these expts. narcosis and paralysis were absent. The narcotic Mg action upon the heat centers is outweighed by the stimulating effects of tetrahydronaphthylamine. C. J. W.

Pharmacodynamic action of tertiary trichlorobutyl esters. A. LOEWY AND R. WOLFFENSTEIN. Berlin. *Arch. exp. Path. Pharm.* 79, 318-36(1916).—Esters of the following acids were studied: acetic, chloroacetic, trichloroacetic, diethylaminoacetic, dimethylaminoacetic, piperidylacetic, propionic, isovaleric, diethylaminoisovaleric, pyruvic, neutral malonic, neutral diethylmalonic, acid diethylmalonic, mixed malonic, allophanic, dibromocinnamic. (These esters are described by Wolfenstein, Loewy and Bachstet (C. A. 10, 768).) In general trichlorobutyl esters are not split in the body and therefore do not show the narcotic action of the alc. The only sleep-producing compd. was the ester of diethylaminoacetic acid. Its action, however, is not identical with that of the alc. The various esters had characteristic actions, which did not resemble those of the components. Especially noticeable was the strychnine-like effect produced by the propionic, isovaleric and allophanic acid esters. C. J. W.

Destruction of morphine and morphine derivatives during the development of the chicken embryo. MAX GRÜTER. Univ. Zürich. *Arch. exp. Path. Pharm.* 79, 337-60(1916).—Fertilized and incubated eggs may be injected with morphine, heroine and codeine solns. (up to 2 cc.) without preventing the further development of the embryos. When the embryo was completely developed, the heroine was always completely destroyed, the morphine was found between 50 and 100%, while the codeine could be quant. recovered. Increased O addition during incubation produced a complete destruction of the morphine. If the embryo is killed when about half developed, all the alkaloids can be recovered quant. Thus a certain morphological stage of development is necessary in order to destroy the 2 alkaloids. The injected embryo is thus to be considered as a chronically poisoned individual. Expts. with various amts. of O indicate that the destruction of the alkaloids by the completely developed embryo is an oxidation process. The reason why morphine and heroine are decomposed and codeine and dionine are not, probably lies in the manner of the esterification of the phenol hydroxyls. C. J. WEST.

The fate of proteinogenetic amines in the animal body. M. GUGGENHEIM AND WILH. LÖFFLER. Basel. *Biochem. Z.* 72, 325-50(1916).—The expts. indicate that the proteinogenetic amines, isoamylamine, phenylethylamine, p -hydroxyphenylethylamine, indoleethylamine, β -imidazoleethylamine, lose their poisonous properties in the body. This is not the result of a coupling but of deamination and oxidation. The end products are carboxylic acids with the same number of C atoms as the original amine. Thus isoamylamine gives isovaleric acid, phenylethylamine gives phenylacetic acid and indoleethylamine, indoleacetic acid. The presence of β -imidazoleacetic acid has not been established but is very probable. The carboxylic acids are excreted as such or further decompd. in the body. Intermediate products of the oxida-

tions of the amines to the acids are the corresponding alcs., isoamyl alc., phenylethyl alc. and *p*-hydroxyphenylethyl alc. These alcs. can, in several cases, be isolated and characterized by perfusion of the surviving liver with the amine. A confirmation of this is the fact that these alcs. are oxidized by the isolated liver to the corresponding acids. Normal blood and serum of man and animals have a tonus-accelerating action upon the isolated guinea-pig intestine. The action is ascribed to a substance, sol. in alc. and stable towards heat. C. J. WEST.

Behavior of 3-hydroxythionaphthene (thioindoxyl) in the organism. Thioindican. ERWIN SCHWENK. Kaiser Wilhelm Inst. *Biochem. Z.* 72, 383-91(1916).—After feeding 3-hydroxythionaphthene to rabbits, thioindican and thioindoxylglucuronic acid were isolated from the urine. *Thioindican* was synthesized for comparison by the action of 5 g. hydroxythionaphthene and 15 g. ClSO_3H in 50 g. $\text{C}_6\text{H}_5\text{N}$. After standing 2 hrs. at 38° and 24 hrs. at 20° , the $\text{C}_6\text{H}_5\text{N}$ was removed *in vacuo*, 26 g. KOH in 50 cc. H_2O added and the mixt. again distd. *in vacuo*. Recrystd. from H_2O , 65% of the theory of thioindican was obtained, 4-sided, silver-glistening leaflets, reddened at 180° , m. unsharp at 225° . In the presence of light catalyzers it is easily decompd. by light. The *potassium thioindoxylglucuronate* was isolated as needles, m. $199-200^\circ$ (decompn.), $[\alpha] -66.12^\circ$. C. J. WEST.

R. A. GORTNER.

Resistance of starved and normal fishes to low oxygen and the effect upon this resistance of acids, alkalies, salts, etc. MORRIS M. WELLS. Univ. Chicago. *Science* 43, 183-4(1916); cf. *C. A.* 8, 1162.—This study is not yet complete. Among the results announced may be mentioned the devising of an app. that will furnish a flow of about 1 l. per min. of O-free H_2O . Starving fishes show an increase in their resistance, i. e., a decrease in their susceptibility to low O during the first 3-8 weeks of the starving period; this resistance rapidly decreases toward death, which occurs in 12-16 weeks. The reaction of water has a marked effect upon resistance, alk. H_2O being more toxic in concns. as small as $N/3000$. If the H_2O is alk. fishes live longer corked in low-O H_2O than if the H_2O flows constantly through the exptl. bottle. L. W. RIGGS.

Action of several porphyrins upon paramecium. HANS FISCHER AND G. A. V. KEMNITZ. Univ. Munchen. *Z. physiol. Chem.* 96, 309-13(1916).—At a diln. of 1:50,000 both hemato- and mesoporphyrin have the same effect on paramecium. At a diln. of 1:200,000 mesoporphyrin is more active; it continues to be active up to 1:8,000,000. Urine- and kotporphyrin, in concns. of 1:80,000 or 10,000 have no action. C. J. W.

Inorganic constituents of alcyonaria (CLARKE) 8.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Development of the baking powder industry. LUDWIG WEIL. *Pharm. Ztg.* 60, 697-8(1915). W. O. E.

Determination of preservatives in caviar. KÖPKE. *Arb. kais. Gesundh.* 50, 31-7(1915).—Analyses of 12 samples of caviar showed an av. compn. of protein 26, fat 15, water 50, ash (6 samples) 4%; the NaCl content varied from 1.5 to 9%. $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ was reported in 5 of the samples, varying in amt. from 0.09 to 1.17%. $(\text{CH}_3)_4\text{N}_4$ was found in 6 samples in amts. from 0.005 to 0.103%; but one of these 6 contained borax. For the detn. of borax 10 g. caviar were treated with 10 cc. of fuming HCl on the water bath in a flask fitted with a reflux condenser until dissolved. Fifty cc. of MeOH were then added and distd., the process being repeated until the dis-

tillate was free of H_2BO_3 , which required not more than 3 additions of MeOH. The distillate was neutralized with 0.5 N NaOH, an excess of 2.5 cc. being added, evapd. in a Pt dish and ignited. The residue dissolved in dil. HCl was treated with 30 cc. of 40% neutral Na citrate, 1 drop of neutral 1% phenolphthalein added and sufficient mannitol to make a 10% soln. of the latter. This soln. was then titrated with 0.1 N NaOH, 1 cc. being equiv. to 0.0062 g. H_2BO_3 . This procedure was according to an unpublished method of Pfyl, which was shown to be reliable by control expts. made by adding H_2BO_3 to caviar containing no borax. $(CH_2)_6N_4$ was detd. as HCHO according to Auerbach and Barschall (*Arb. kais. Gesundh.* 22, 591(1905)). An aliquot part of the filtered distillate was made alk. and a measured excess of alc.-free standard I soln. added. After standing 15 min. the I was titrated back with 0.1 N $Na_2S_2O_3$ and the HCHO calcd. to $(CH_2)_6N_4$. This method was also tested by control expts. The amt. of $(CH_2)_6N_4$ or HCHO in caviar does not remain const. owing to a reaction of the HCHO with the albumin present. L. W. RROGS.

Utilization of cull Florida citrus fruit. A. McDERMOTT. *J. Ind. Eng. Chem.* 8, 136-8(1916).—The culls sometimes amount to 10% of a given lot of fruit, generally less. Usual causes are, extreme over- or under-size, stem-end rot, traumatic injuries to the peel, and blue molds. The problem is to find satisfactory processes for pressing the juice for at least 2 years and for removing the flavoring oil from the peels. Pasteurization renders the juice sterile apparently for an indefinite period, but after two weeks the product darkens in color and ultimately becomes offensively acrid. Removal of air prior to sealing is effective in checking the darkening. Charging the juice with CO_2 and replacing the air above it gave some specimens which remained unchanged for two years or more. The most effective process is as follows: Pasteurize under as complete a vacuum as possible (28 in.) at a temp. slightly above that of boiling H_2O and then seal. The above applies to the juice of oranges and grapefruit; lemon juice differs in that simple pasteurization is all that is necessary to prevent deterioration. The oils expressed from the peels of the culls fulfill all requirements. The decompn. caused by exposure to air can be obviated by adding 10% by vol. of abs. alc., or by keeping in a dark cool place even if protecting agents are present.

Analysis of maple products. V. J. F. SNELL. *J. Ind. Eng. Chem.* 8, 144-6(1916).—Observations on maple sirup incidental to a search for new methods of detecting adulteration.

P. J. DONK.

Lye hulling of corn for hominy. J. W. MARDEN AND J. A. MONTGOMERY. *J. Ind. Eng. Chem.* 7, 850-3(1915).—Results are given of lab. expts. on the hulling of corn giving different chemicals used, strength of solns., time of heating and washing and temp. No common substitute for lye could be used. Not more than 2 lbs. to 12 gals. of H_2O nor less than 1 lb. to 12 gals. of H_2O could be used. At a temp. of 70° about $1\frac{1}{2}$ hrs. are required, at 90° less time. Efficient stirring is essential to good results.

P. J. DONK.

Pentosans contained in rice. T. KATAYAMA. *J. Chem. Ind. Japan* 18, 1364(1915).—The methylpentosans in all the rices and rice starches amount to nearly 1%. Ordinary rice contains more pentosans than glutinous rice. Uncleaned rice contains more pentosans than cleaned rice. The pentosan content has no relation to the difficulty of saccharification.

P. J. DONK.

Report of the committee on standard methods for the bacterial examination of milk. M. P. RAVENEL, H. W. CONN, W. H. PARK, J. F. ANDERSON AND R. S. BRISSED. *Am. J. Pub. Health* 5, 1261-2(1915).—Not less than 10 cc., taken in sterile containers, should be plated on agar containing 3 g. per l. meat ext. and the best peptone. The

reaction should be between 0.5 and 1. Plates should be incubated at 37° for 48 hrs. Samples should be dild. so that the count is between 30 and 200. A lens magnifying 2.5 times should be used. Many important tests have not been recommended because of the study required to apply them for practical use. J. GAUB.

A sanitary study of condensed milk. WILLIAM H. PARK, M. C. SCHROEDER, N. Y. Health Dept., AND PAUL BARTHOLOW. *Columbia Univ. N. Y. Med. J.* 102, 1073-83(1915).—The work covers the bacterial content of raw milk, the process of condensing, the sanitary conditions of the process, the bacterial content of condensed milk and a review of chem. analyses of condensed milk. The use of inferior milk for condensing is a general practice, the bacterial count ranging from 77,000 to 1,662,000. Since the raw milk is concd. to one-half its volume, the counts may be divided by two and the milk graded bacteriologically fair. Condensed milk intended for confectioners showed a much greater number of bacteria than that intended for domestic consumption (up to 340,000,000 organisms). Evapd. milk as a rule contains a much lower number of bacteria than condensed milk, due in part to the higher temp. to which it is subjected and in part to double sterilization. Chem. examn. showed the following variations in compn.: sucrose 33.15 to 49.85%, lactose 7.57 to 15.34% and protein 6.73 to 13.59%. Tabulated analyses furnished by Atkinson (N. Y. Dept. Health) are included. A. H. RAHE.

Detection of sucrose in milk. A. DEVARDA. *Arch. Chem. Mikros.* 8, 69-71 (1915).—A common form of adulteration of raw milk consists in addition of sucrose and H₂O. The sucrose is detected by the Ph₂NH reaction, the lactose being pptd. with basic lead acetate. The pptn. of the lactose is complete only when the concn. is below 6%. Under certain conditions the lactose content may rise above this value, and results on sucrose are unreliable. Tables are given. C. S. MUDGE.

The useful and the injurious in coffee, with special consideration of the Thum method (of cleaning). HANS FREUND. *Pharm. Zentralhalle* 56, 343-8(1915).—In cleaning coffee by the Thum method, the unclean product is placed in a horizontal revolving perforated drum which is placed within another vessel containing H₂O at about 40-70° to such a depth that the water entering the perforations stands several cm. high in the drum. Within the drum are from 4 to 8 broad brushes which revolve in an opposite direction to the drum. The treatment lasts from 1 to 2 min. for best grades of coffee, up to 5 min. with poorer grades, the addition of NaCl or Na₂CO₃ to the H₂O being sometimes necessary for the latter. The H₂O is then drawn off, the coffee dried in the same drum and then roasted. The coffee is well cleaned and the amount of material extracted is of no consequence. Analyses are given of a Santos coffee raw, after roasting in the usual manner, and after cleaning by the Thum method, and of an average wash water. The latter has a grayish brown turbid appearance and under a microscope shows earthy impurities, vegetable tissues, and a rich bacterial flora. C. O. EWING.

Coffee and chicory. P. CARLES. *Ann. chim. anal.* 21, 33-5(1916); see C. A. 10, 643. E. H.

The alkali method for the determination of fat in ice cream and condensed milk. C. M. BRADBURY. *Virginia Dairy and Food Div., Circ.* 42, 4 pp.(1914).—The short method for detg. fat in milk and cream (cf. Wisconsin Sta., *Bull.* 16, 14 pp.(1888)) has been adapted to the detn. of fat in ice cream and condensed milk. E. J. C.

Examination of cocoa. VON LUEHMANN. *Apoth. Ztg.* 30, 642(1915).—Reference is made to previous papers of Keller and of Hanausek (cf. C. A. 643). W. O. E.

Determination of fat in cacao products. W. LANGE. *Arb. kais. Gesundh.* 50, 149-57(1915).—The subject of fat extn. by the Soxhlet and similar methods is re-

viewed with especial mention of the work of Farnsteiner (cf. *C. A.* 3, 1042). Expts. by L. with Soxhlet extn. showed that 15 hrs. were required to ext. 99.6% of the fat from cacao paste containing 50.45% of fat; and that 3.8% of the total fat was extd. during the last 5 hrs. Cacao powders containing, resp., 34.03 and 15.31% of fat gave results parallel to those of the cacao paste. Chocolate containing 30.52% of fat yielded 99.7% of its fat during the first 2.5 hrs., and milk chocolate with 32.07% of fat gave a parallel result. Notwithstanding the sparing soly. of theobromine and caffeine in Et_2O , the large amt. of Et_2O used in a 20 hr. extn. (13 liters) would dissolve a portion of these substances, thus introducing an error in the fat detn. As an improvement on the Soxhlet method, L. recommends the following procedure: A weighed 250 cc. wide-mouthed flask is fitted with a rubber stopper carrying a tube bent at a right angle to be attached to an air-pump, and a filter tube the wide part of which is 3.5-4 cm. in diameter and 8 cm. long. A Witt filter plate with openings 0.75 to 1 mm. is placed in the filter tube, covered with an asbestos mat, washed free of fine fibers with water under pressure, and dried with alc. and Et_2O . Five to 10 g. of powdered cacao product, according to the fat content, are placed in the tube, leveled, 10-15 cc. of Et_2O added and the top of the tube covered with a watch glass or channeled cork. As soon as the Et_2O runs down to the plate a gentle exhaust is applied to draw the fat soln. into the flask. This process is repeated with 7-10 cc. of Et_2O until 100 cc. have been used. The flask is then exchanged for a similar weighed flask, the powder on the mat stirred with a rod and the extns. repeated until 50 additional cc. of Et_2O are used; the process so far requires 30-46 min. The Et_2O is then distd. and the flasks with the fat dried to constant wt. in a steam drying oven. A comparison of analyses of 12 samples of cacao products containing from 14.06 to 51.77% of fat showed that in every case L.'s method gave slightly lower results than the Soxhlet, the extremes being 0.09 and 0.40%. Analyses of 9 samples of cacao paste from various localities gave a fat content of 50.66 to 57.30%. To compare the rapidity of drying to const. wt. in a Soxhlet and in a wide-mouthed flask having neck diameters, resp., of 18 and 32 mm., 3 g. of cacao fat placed in each were dissolved in Et_2O , the Et_2O distd. off, and the flasks placed in the steam drying oven. After 1 hr. the amts. of volatile matter retained in the flasks were 0.0390 and 0.0018 g., resp.; after 2 hrs., 0.0068 and 0.0008 g. Petr. ether in place of Et_2O gave similar results.

L. W. RIGGS.

Sand content of Dutch cocoa. J. BOGS. *Pharm. Zentralhalle* 56, 495-6(1915).—Ash 2 g. in Pt dish, avoiding overheating, digest 0.5 hr. with 10% HCl, decant through a filter, digest 0.5 hr. with half satd. Na_2CO_3 soln., filter through same filter, wash, ignite and weigh. Wt. gives the amount of pure sand (SiO_2). A pure sand content above 0.5% indicates more than 3% of cocoa shells and points toward adulteration.

C. O. EWING.

Content of stems in Java tea and testing of tea. J. J. B. DRUSS. *Chem. Weekblad* 13, 66-71(1916).—D. agrees with the statement of Besson (*C. A.* 9, 1641) that the valuations of tea should not be based upon the content of stems. The % of stems was detd. as follows: 5 g. tea are added to boiling H_2O , which is then vigorously stirred and the leaves wholly disintegrated. The liquid is poured off and the tea again covered with water. The stems are then picked out with a forceps. Stems and leaves are then dried separately at 105° and weighed and % stems calcd. Java teas contain a higher amt. of stems than Japan teas, while British Indian and Tonkin teas contain about as much as the former. D. shows in a table that the more expensive brands of tea contain a higher % of stems than the less expensive brands, which may be explained by the fact that the finest parts fall through the finer sieves and contain hardly any stems at all.

J. T. FLOREN.

Direct determination of water in spices. T. FOLPMEER. *Chem. Weekblad* 13,

14-6(1916).—On account of the high content of volatile oils in certain spices, considerable difference may be expected between the results of the moisture detn. according to the direct and the indirect methods. Differences between the indirect and direct method for ground cloves were as high as + 8.6 to 19.3%, for mace 4.7 to 6.7% and for ginger and cinamon as low as -1 to +0.2% and -0.7 to 1.5%, resp. Higher results were obtained with xylene than with either benzene or toluene, which is attributed to the higher b. p. of xylene, as this causes decompn. J. T. FLOHL.

Microscopy of starch in bread. T. F. HANAUSEK. *Arch. Chem. Mikros.* 8, 72-8 (1915).—H. was able to identify microscopically the starches found in the various war breads after baking. The use of stains for the identification is not advisable.

C. S. MUDGE.

Chemical constitution of proteins of wheat flour and its relation to baking strength. M. J. BLISH. *J. Ind. Eng. Chem.* 8, 138-44(1916).—Attempts have been made by investigators to correlate the baking strength of flour with some chemical or physical factor but this problem is not completely solved. Lab. tests invariably furnish an infallible guide, but it is necessary to mill the wheat and have a sample actually baked into a loaf of bread by an expert baker before its strength can be accurately ascertained. The factors which may influence baking strength are as follows: Gliadin-glutenin ratio, crude gluten, physical state of gluten and sugar content, enzymes, concn. of H ions and sol. proteins. All these are discussed at length in the article. P. J. DONK.

The staling of bread considered from the physiologico-chemical point of view. I. J. R. KATZ. Amsterdam. *Z. physiol. Chem.* 95, 104-29(1915).—Bread becomes stale chiefly because the starch grains become harder and have less capacity for swelling, and a part of the sol. polysaccharides in the grains becomes insol. There is a transfer of water from the starch to the gluten, causing the bread to become crumbly. Finally, the consistency of the gluten skeleton of the bread has a certain influence upon the consistency of the bread, which makes tangible the influence of the above-mentioned changes. II. *Ibid* 136-46. The reversed changes take place when bread is baked; the amt. of sol. polysaccharide increases, the capacity for swelling increases, etc. Thus the process of becoming stale is a sort of partial return to the condition before baking. III. *Ibid* 147-51. The above-mentioned changes of starch upon heating are characteristic of all kinds of starch. C. J. WEST.

The change in the microscopic structure of bread during the process of becoming stale. E. VERSCHAFFELT AND FR. E. VAN TEUTEM. Amsterdam. *Z. physiol. Chem.* 95, 130-5(1915). C. J. WEST.

Soluble carbohydrate contents of feeding stuff as standard of quality. G. B. VAN KAMPEN. *Chem. Weekblad* 12, 902-10(1915).—K. discusses various methods for establishing a standard of quality for feeding stuffs. He shows that the sugar content varies with the quality of the material. Analyses show that compressed cakes of cattle feed of a low grade contain 3.06% sucrose, while those of av. grade contain 6.27% and cakes prepd. in the lab. contain 8.64%, all being given in terms of fat-free org. matter.

P. J. DONK.

Nutritive substance separated from pressed pupa waste of silkworm. R. INOUE. *J. Chem. Ind. Japan* 18, 1319(1915).—Boil 100 g. of the waste with 300 cc. of 25% H_2SO_4 for 16 hrs., filter, neutralize with baryta and filter again. Evap. the filtrate *in vacuo* to crystn. and dry the crystals of the nutritive substance. The compn. of this substance is: H_2O 27.41, ash 2.96, P_2O_5 0.37, sugar (glucose) 2.24, total N 11.05%. Expts. with animals show that the substance mixed with rice or similar food increases the nutritive value of the latter, also that there exists no difference between Liebig's meat ext. and the pupal nutrient on culturing bacteria. P. J. DONK.

Effects of refrigeration upon the larvae of *Trichinella spiralis*. B. H. RANSOM. Bur. Animal Ind. *J. Agr. Research* 5, 819-54(1916).—Results are given of tests in which quantities of trichinous meat varying in wt. from a few g. to nearly 400 lbs. were frozen and kept for periods varying from a few min. to 57 days at various temps. below 32° F. Artificial digestion of trichinous meat for 24 hrs. at 38 to 40° in a fluid consisting of water 1000 cc., HCl (d. 1.19) 10 cc., scale pepsin (U. S. P.) 2.5 g., and NaCl 5 g., has no apparent effect upon the activity or structure of the trichinae, released from their capsules by the process of digestion. Trichinae thus released from their capsules may remain alive and retain their normal activity for 10 days or more when kept in a 0.6% NaCl soln. at about 20°, and have been found alive and moderately active at the end of 26 days. They may likewise be kept alive for 2 weeks or more in tap water at about 20°. Trichinae have been kept alive and very active for 11 days in a 2% NaCl soln. at about 20°. Trichinae in tap water warmed to 38° become inactive within a few hrs., but may be kept in a 0.6% NaCl soln. at this temp. for a similar length of time without apparent injury. In the practical application of refrigeration as a means of destroying the vitality of trichinae, meats should be refrigerated at a temp. not higher than 5° F. for not less than 20 days, a period which allows a probable margin of safety of nearly 10 days. A short bibliography is appended. W. H. FRY.

Utilization (of prickly pear) as fodder for stock. T. H. JOHNSTON AND H. TRYON. *Rept. Prickly Pear Traveling Comm.*, Queensland 1912-14, 35-7, 52-3, 89, 113.—Analyses are given for both the fresh and the dried fruit of 6 different varieties of the pear.

E. J. C.

Sugar beet leaf feeding and drying. F. REDLICH. *Wiener landw. Ztg.* 65, 595-7, 603-4, 611-2(1915); cf. *C. A.* 9, 943.—The article gives the results of two sets of feeding expts., one carried out to det. the digestibility of sugar-beet leaves, the other to det. the physiological influence of the quantity of oxalates contained in the av. ration. There is also given a description with illustrations of several driers suitable for drying the leaves. It is stated that sugar-beet leaves make a very good feed for cattle and especially for milch cows, the oxalates contained by the av. ration increasing the fat content of the milk (by approx. 0.5%) without diminishing the yield. 50 to 60 g. of $\text{Ca}_3(\text{PO}_4)_2$ should be added to the daily ration to supply the lime required by the sol. oxalates and otherwise removed from the animal. Only mature leaves should be fed since they contain a lower % of oxalates. The leaves can be preserved without drying by allowing them to sour under the action of a pure culture of lactic acid bacilli. Chem. analyses of both fresh and dried sugar-beet leaves are given. C. F. MILLER.

The poisoning of live stock by plants of the sorghum group (FRANCIS) 11D. Ripening of the wild goose plum (MCHARGUR) 11D.

Albuminous food from oil residues, etc. V. GRAFE and K. PECHER. U. S., 1,169,634, Jan. 25. Residues from the manuf. of cottonseed, cacao, linseed or other vegetable oils are treated with a soln. of NaOH and Na_2CO_3 , or other alkali, while heated, and the resulting product is neutralized with acid to ppt. proteins dissolved in the soap soln. formed. Then the soap soln. is sepd. from the solids and the latter are washed with hot and cold H_2O . The product may be used in "meat substitutes," etc.

Shredded cereal food. J. L. KELLOGG. U. S., 1,170,162, Feb. 1. Wheat, corn, oats or other grain is crushed to a powder, made into a dough and cooked. It is then dried, broken into small pieces, formed into ribbon-like shreds and baked or toasted.

Lactic acid in bread-making. D. BRATTY. U. S., 1,170,474, Feb. 1. Lactic

acid is formed into a substantially dry mixt. with starch for use with soda in making biscuits, bread, etc.

Vinegar manufacture. J. B. PAGE. U. S., 1,171,065, Feb. 8. Melon juice is clarified, by centrifuging, *e. g.*, and is fermented and acetified after concg. by heating at a low temp. and then for a short time at a higher temp. to give the juice a brown color.

Non-hygroscopic malt extract preparations. F. HOFFMANN-LA ROCHE & Co. Ger., 285,427, Mar. 4, 1913. The hygroscopic properties common to malt exts., which render transportation difficult and induce fermentation and molding, are destroyed by the addition of casein-Ca to the ext. A prepn., *e. g.*, which is made from 1 part casein-Ca and 2 parts malt ext., manifests upon protracted standing *in pleno* no alteration; the powder remains dry and does not cake. Dry malt ext. may be mixed directly with casein-Ca, or both of these constituents may be dissolved together, and the soln. evapd. to dryness. The resulting products are applied dietetically.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Liquid chlorine (ORNSTEIN) 4.

Purifying water containing acids. J. C. HECKMAN. U. S., 1,171,046, Feb. 8. Water containing acids, *e. g.*, mine water, is purified by passing it through a mass of granulated blast furnace slag containing CaO.

Distilled water. B. BLEICKEN. Ger., 285,773, Dec. 18, 1913. Addition to 283,415. A modified app. is specified.

Rapid filtration plant with reverse rinsing. O. KOERNIG. Ger., 285,872, Apr. 8, 1914.

Preventing agitation of slime sediment. RICHTER & RICHTER. Ger., 285,487, June 26, 1913.

Container for treating waste water slimes. K. IMHOFF and H. BLUNI. Ger., 285,486, Feb. 7, 1914. Addition to 275,498 (C. A. 8, 3340). The flow in the containers is started and maintained by heating a portion of the slime. For this purpose a current of warm air may be led through the slime.

Purifying sewage. G. W. NAYLOR and J. F. NAYLOR. Brit., 20,579, Oct. 6, 1914. In app. for purifying sewage, air is passed through the sewage in a tank from below a false bottom, formed of a flexible fabric such as filter cloth, felt, canvas, lawn, woven or perforated metal, which may be supported on the air-supply pipes, or on caps or jets which may carry radial perforated pipes, or on supports projecting from the base of the tank. The space below the false bottom may be divided into compartments by partitions. Frames spaced apart may be used. A thin layer of granular material or dried sludge may be placed on the false bottom. The fabric may be supported by sheets of wire netting or expanded metal.

Disinfectants. J. CHALLIS. Brit., 21,000, Oct. 15, 1914. Disinfectants and antiseptics are made by boiling together until saponified, 5 gals. phenol or of cresylic acid, 3 gals. vegetable oil (linseed, olive, or rape), 12.5 lb. KOH, and 4 gals. H₂O, and then adding 3.75 gals. acetone. In a modification, the acetone may be partially replaced by alc., benzene, naphtha, or other light distillate, and tar acids or oils other than cresylic, *e. g.*, creosote may be used.

Vacuum disinfection. APPARATEBAUANSTALT UND METALLWERKE AKT.-GES. Ger., 284,972, Aug. 27, 1912. Paraformaldehyde is volatilized in a small externally

heated vessel connected with a vacuum vessel and steam supply. Suitable app. is specified.

Vacuum disinfection. APPARATEBAUANSTALT UND METALLWERKE AKT.-GES. Ger., 286,131, July 22, 1913. Addition to 284,972 (*supra*). The process of the principal patent is modified in that instead of paraformaldehyde, other compds. are used, which upon heating yield disinfecting vapors, such as acetone, pinacol, etc., in solid or soapy form. When acetone or pinacol are heated as specified, aldehyde-like compds., with strong disinfecting power, are formed, suitable for the disinfection of skins, hides, and hair goods. When solid spirit is used, large amts. of alc. vapors are evolved promptly, and these are also disinfecting. This modification of vacuum distn. is especially suitable for disinfecting books and paper goods, since the resulting vapors are very dry.

15. SOILS AND FERTILIZERS.

R. O. F. DAVIS.

Rapid method for removal of solid residue in the determination of nitrogen in soils. C. J. KING. *Chem. Analyst* 15, 19(1915).—Fit a 10 cm. Büchner funnel with a disk of linen, about 120 mesh per inch. Moisten the linen and draw to the perforated disk by suction. To the digestion flask after cooling add about 100 cc. N-free water, shake vigorously and while still hot, pour upon the linen filter, applying suction. Wash the residue remaining in the flask several times with 25 cc. portions of hot H₂O. Finally, transfer all of the residue to the filter and continue washing until the suction flask contains about 600 cc. Disconnect the flask and distil in the usual manner. The total time required is only 6 or 8 min. The method is just as effective in preventing bumping as the official decantation method.

H. M. LANCASTER.

Nitrogen content of humus of arid soils. F. J. ALWAY AND E. S. BISHOP. *J. Agr. Res.* 5, 909-16(1916).—Earlier investigators have stated that humus in soils of arid regions carries more N than that in soils of humid regions. Study of samples of soils from California confirmed this view.

R. O. F. D.

Note on the effect of changes in the viscosity of water on the results of mechanical analyses conducted at varying temperatures. G. W. ROBINSON. Univ. Coll., North Wales, Bangor. *J. Agr. Sci.* 7, 142-3(1915).—A change in temp., by altering the viscosity of water, affects the values obtained by sedimentation. It is recommended, therefore, that sedimentations be carried out at as uniform a temp. as possible, say 12 to 14°.

W. H. FRY.

A detailed study of effects of climate on important properties of soils. C. B. LIPMAN AND D. D. WAYNICK. *Soil Science* 1, 1-48(1916).—A study was made of the physical, chemical and bacteriological characteristics of the soil from plots of a tri-state soil exchange experiment. The plots are located at the Maryland, Kansas and California Exp. Stas. Soil from each state was exchanged with soil of the 2 other states, and laid in position. After 7 years the soils have changed markedly in color. The Kan. and Md. soils at Cal. become a deeper red; Cal. and Kan. soils become bleached to a light gray or yellow gray at Md. In general, the hygroscopic coeff., the moisture equiv. and the wilting point of any of the soils increase when the soil is moved to Cal. Bacterial numbers increase in arid soils placed under humid conditions, and the opposite is true for humid soils. NH₃, NO₃, and N-fixation follow the general trend of bacterial count. This applies with nitrification only with certain forms of N. Cellulose destruction by soils proceeds with greater rapidity under arid than under humid conditions with any given soil type. Cellulose destruction appears to follow in general

the opposite course of other micro-organic activities in soils as affected by climate. Marked changes in the acid sol. constituents of soils are wrought by climatic effects. The Cal. soil increases in Ca at Kan. and Md. and loses in Fe. The general tendency is for soils to increase in Fe and decrease in Al when placed under arid conditions and *vice versa*. Interesting data are submitted on the total H₂O-soluble constituents in the soils studied. Large increases occur in the Cal. soil when it is moved to Kan. and Md. The Md. soil gains in H₂O sol. matter when moved to Kan. or to Cal.

J. J. SKINNER.

A peculiar clay from near Mexico City. E. W. HILGARD. *Proc. Nat. Acad. Sci.* 2, 8-12(1916).—A sample of clay from near Mexico City showed the remarkable property of swelling enormously when wetted, increasing in vol. 25 to 32 times. Sp. gr. of the clay was 2.25. Analysis by acid digestion showed sol. Na salts 2.60, lime 9.06, MgO 17.11, Al₂O₃ and Fe₂O₃ 5.24 and SiO₂ 43%; by fusion, lime 8.9, MgO 27.07, Al₂O₃ and Fe₂O₃ 10.63 and SiO₂ 51.43%. The predominant base was magnesia instead of alumina as in ordinary clays. This clay is readily decomposed by dil. acids. The name lucinite is proposed for it.

R. O. E. D.

Carbon and nitrogen changes in soils variously treated: Soil treated with lime, ammonium sulfate and sodium nitrate. R. S. POTTER AND R. S. SNYDER. *Soil Science* 1, 76-93(1916).—The total N detns. show there is a smaller loss or a greater gain of N for the limed soils than the corresponding unlimed soils. The loss of N from the soils treated with NaNO₃ and the gain of N in those treated with both NaNO₃ and Ca point to denitrification.

J. J. SKINNER.

Effect of grinding on the lime requirement of soils. R. C. COOK. *Soil Science* 1, 95-98(1916).—Using the Veitch method of detg. the Ca requirement of soils, acidity was increased by grinding sandy soils of N. J. Ground quartz sand was more acid than unground. These results are opposite to those of Brown and Johnson (*J. Am. Soc. Agron.* 1, 216) who found that grinding sandy soils decreased acidity. The finer the soil was ground the more basic it became, and its basicity was roughly proportional to the amt. of sand contained. C. explains that this sand possibly contained basic internal constitution. It is concluded that soils should not be ground when used for detg. Ca requirement by the Veitch method.

J. J. SKINNER.

The influence of some common humus-forming materials of narrow and of wide nitrogen-carbon ratio on bacterial activities. P. E. BROWN AND F. E. ALLISON. *Soil Science* 1, 49-75(1916).—Working with Miami sandy loam it was shown that animal manures gave the greatest effect on ammonification. Oat straw and corn stover had a less effect than the manures, and clover and cow peas showed the least effect. This increase was independent of the N-C ratio of the materials added and was probably dependent on the chem. compn. of the substances. The dried-blood-fresh soil method gave better results than the casein-fresh soil method. NO₃ was increased in the same way as NH₃ by the various organic materials. The leguminous green fertilizers exerted somewhat greater effects than the manures and more influence than the non-legumes. The increase in NO₃ was independent of the N-C ratio and was favored by manures to a large extent. Straw, stover and non-legumes had almost as great an effect as manures, and leguminous hay had the least effect. Dextrose gave better results in the azofication expts. than mannitol. There was little similarity between the effects of the different organic materials on the different bacterial processes. The manures and legumes increased the crop of oats. The substances with wide N-C ratios decreased the crop yield while those of narrow ratios gave increases. The influence of the various substances applied to the soils was noted on a 2nd crop of oats, but the relative effects were different. The non-legumes had as great an influence as the legumes; previous conclusions are confirmed that with the use of non-legumes sufficient

time must elapse for azofication to occur if as beneficial effects are to be secured as with legumes. The N-C ratio of the materials applied to the soil did not seem to be of as much importance in detg. the effect on the 2nd crop of oats as in the case of the 1st crop.

J. J. SKINNER.

The history of lime-nitrogen. A. FRANK AND N. CARO. *Chem. Ind.* 38, 445-6 (1915).—A review.

F. W. SMITHER.

Boron; its absorption and distribution in plants and its effect on growth. F. C. COOK. Bur. Chem., U. S. Dept. Agric. *J. Agr. Res.* 5, 877-91 (1916).—The investigation was undertaken to det. the absorption of B and its distribution in plants grown on soils fertilized with horse manure treated with borax or calcined colemanite to destroy larvae of the house fly. Manure treated with these materials was left 10 days and then applied to the soil. The amt. used was 0.63 lb. per 8 bu. or 10 cu. ft. 20 tons to the acre amounted to 216 lbs. of borax per acre. It made little difference in the amts. of B absorbed by the plants whether borax or colemanite was used. Most plants absorbed B in proportion to the amt. present in the soil. Leguminous plants absorbed most and wheat and oats little B. Distribution in the roots, tops and fruit of leguminous plants is fairly even. Potatoes had more B in the roots than in the tops. The yield of wheat was very slightly affected. Not more than 0.62 lb. of borax and 0.75 lb. of colemanite should be added to 10 cu. ft. of manure and the treated manure should be mixed with untreated manure when used for leguminous plants. For other plants B-treated manure should not be used at higher rate than 15 tons per acre. Cf. C. A. 9, 3313.

R. O. E. D.

The use of low-grade phosphates. JAMES A. BARR. *Bull. Am. Inst. Mining Eng.* 1916, 243-5.—Phosphate rock concn. processes in operation at the present time involve tailing losses of 15-25% of available phosphate through the escape of fine particles with the SiO_2 . A radical improvement of methods would make available approx. 100,000,000 tons of low-grade Florida and Tennessee rock carrying 68-72% $\text{Ca}_3(\text{PO}_4)_2$. Smelting or electrometallurgical processes are possibilities but perhaps the most simple solution of the problem is the use of finely ground rock (90% through 100 mesh) in the raw state.

H. L. OLIN.

Determination of manganese in soils. A. K. BRYNILDSEN. *Tidsskrift Kem. Farm. Terapi* 12, 317-23 (1915).—Ext. the ignited soil with HCl and dil. an aliquot representing 2 g. to 400 cc. and boil. Neutralize the acid and add NaOAc and HOAc. After boiling 2 min. dil. the soln. to 800 cc. and filter off the pptd. Fe and Al. Dissolve and reppt. in the same way. Evap. the combined filtrates and wash solns. to 500 cc. and filter the Fe and Al which may be pptd. at this point. If the HOAc is present in concn. there will be no Mn lost prior to this pptn. At this point $\text{MnO}_2 \cdot \text{H}_2\text{O}$ may sep.; this is readily brought into soln. by oxidizing with H_2O_2 . Treat the AcOH soln. of Mn with Br water which ppts. MnO_2 quant.; filter, wash, treat with KI soln. and titrate the I liberated with 0.01 or 0.001 N $\text{Na}_2\text{S}_2\text{O}_3$. The data obtained by this method agree closely with those by Treadwell's MnSO_4 method, and the figures obtained by oxidizing the MnO_2 and weighing as Mn_2O_4 . The Mn in the various Norw. soils ranged from 0.2% to 0.02%.

A. R. ROSE.

"Electro-potash" as fertilizer. SIGURD RHODIN. *Kungl. Landbruks-Akad. Handl. Tidsskr.* 54, 710-29 (1915).—A report of field expts. which have led to no definite conclusions. The "electro-potash" (electrically treated feldspar) products by the method of Lindblad and Yngstrom are so far the most promising. The fertilizing value of these substances is very largely dependent upon the nature of the humus, type of plant and vegetation period.

A. R. ROSE.

The fertilizer value of sodium chloride. III. H. G. SÖDERBAUM. *Kungl. Landbruks-Akad. Handl. Tidsskr.* 54, 673-95 (1915); cf. C. A. 9, 685, 1525.—An

historical review and a report of field expts. which give no support whatever to the hypothesis that NaCl may replace K salts in fertilizers. A. R. ROSS.

The influence on crop and soil of fertilizers applied to permanent meadow. CHARLES CROWTHER AND ARTHUR G. RUSTON. Univ. Leeds. *J. Agr. Sci.* 7, 197-218(1915).—Plot expts. and the effects of various fertilizers upon soil and vegetation are reported. W. H. FRY.

An apparatus for mixing powdered substances (HUDIG) 1. The chemical evidence of smelter smoke injury to vegetation (MITCHELL) 9.

Fertilizers. KALIWERKE GROSSHERZOG VON SACHSEN AKT.-GES. and K. HEPKKE. Ger., 286,187, Feb. 17, 1914. Finely ground silicates containing K are mixed with finely ground dried MgOH.Cl and moderately ignited. Even at 180-200° the oxychloride evolves large amts. of HCl which acts, in the nascent state, on the ground silicate, disintegrating it. Feldspar, phonolite, leucite, nepheline, or the like, are specified. The mixt. is heated in a furnace of suitable construction, to dull redness. A rotary drum furnace, such as is used for burning cement, calcining MgO, and the like, is preferred. The reaction product sinters but a very little upon heating, and after cooling it may be removed from the furnace as a fertilizer in condition for distribution on the soil. The amt. of disintegrated K is dependent upon the amt. of added oxychloride. The advantages of this process over former methods are economy in fuel and direct applicability of the product.

Fertilizers. W. B. BOTTOMLEY. Brit., 20,789, Oct. 9, 1914. Peat is mixed with an insol., finely divided phosphate, such as rock phosphate, bone ash, or bone meal, and certain aerobic microorganisms, such as those obtained in putrefying gelatin or meat ext., are caused to grow in the mixt., preferably at a temp. of 30°. The phosphates are converted into forms sol. in NH₄ citrate soln. or H₂O.

Phosphates. W. B. BOTTOMLEY. Brit., 20,788, Oct. 9, 1914. Phosphates, particularly Ca phosphates, are rendered sol. in NH₄ citrate soln. by subjecting them at a suitable temp., e. g., 30°, to the action of certain aerobic microorganisms which occur in putrefying organic matter. The finely divided phosphate may be wetted with a 1% soln. of gelatin or meat ext. which has been allowed to putrefy; or the gelatin soln. or meat ext. may be first added and followed by putrefying liquor or a bacterial culture. By long continued action, some of the phosphate may become H₂O-sol., but a week or 10 days is sufficient to convert a large proportion into the citrate-sol. form.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Determination of sugar in liquors and aperitives. ED. DELLE. *J. fabr. sucre* 56, No. 3(1915).—The French laws call for a different rate of taxation on straight liquors and aperitives. The sugar content is taken as the standard for differentiation, those containing more than 200 mg. per l. being termed spirituous liquors and those under 200 mg. per l. aperitives. The official method calls for dealcoholization, return to the original vol. with water, and detn. of the density at 15°. A soln. having d₁₅ 1.087 contains 200 mg. of sugar per l. This figure does not allow for the increased gravity due to sol. matter other than sugar which may be present. To det. correctly the amt. of sugar present it is necessary to dealcoholize, decolorize with animal charcoal, clarify if necessary with Pb acetate, remove Pb, and finally invert and det. total sugars as invert by one of the alk.-Cu-tartrate methods. H. R. SMITH.

Action of ultraviolet rays upon alcoholic fermentation. ROMOLO AND REMO DE FAZI. Rome. *Ann. chim. applicata* 4, 301-29(1915).—The action of ultraviolet rays is favorable to alc. fermentation for a relatively long time (12 hrs.). Beer yeast, exposed to ultraviolet rays for a definite time, increases in activity, and is not killed by the rays even after 14 hrs. exposure. It is possible to select beer yeast by the action of ultraviolet rays. The expts. were carried out in quartz flasks placed about 20 cm. from a Hg lamp used as the source of the rays. A résumé is given of previous work done on this subject. S. LEVY.

Continuous process of rectification, especially of alcoholic fluids. P. WONNEBERGER. Z. *Schiess-Sprengstoffw.* 10, 13-6, 29-31(1915).—W. gives diagrams of rectification app. and reasons why the continuous rectification app. should replace the periodical app. In an app. described in detail which is used in the explosives works the fluid flows from a const. pressure tank through a warmer into the distg. column. The column consists of tunneled compartments. As the fluid flows down over these compartments it is met by a stream of steam going in the opposite direction. The volatilized alc. passes up through the rectifier to a condenser. The water and heavy residue settle to the bottom of the column. The water is drawn from the top of the residue and passed through an app. for heating the incoming assay. The heavy residue is drawn off at the bottom. The advantages of the continuous rectification app. over the periodic consist in higher production, better quality of product, concn. of the impurities, and self-reliant, equable movement of the parts of the app. O. L. T.

Modern liquor tanks for the brewing industry. WERNER BERGS. *Chem. App.* 3, 4-6(1916).—Descriptions, with 7 cuts, of tanks of Al, enameled Fe, and reinforced concrete lined with ebonite. J. H. MOORE.

Dealcoholizing beer. W. BECKER and D. H. MONTGOMERY. U. S., 1,171,306, Feb. 8. Beer is heated to 75° and then sprayed on the surface over which it flows as a thin film maintained at about 75° to distil off the alc. The treatment is repeated as many times as necessary to reduce the alc. to the desired amt.

Yeast from molasses. G. ROTH. U. S., 1,170,110, Feb. 1. Molasses is dild., acidulated and boiled, the clear liquor is drawn off, further dild. and acidulated with H₂SO₄ to cause pptn. of fine suspended matter which is sepd. after stirring or aeration. The clear product thus obtained is mixed with distillers' wash, nutrient salts, etc., pitched with yeast and fermented, with lactic acid bacilli added if desired.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

The testing of cotton and other dressing materials. M. LAHACHE. *Union pharm.*, March 15, 1915; *Repert. pharm.* 28, 4-11(1916).—Simple tests are given for the principal constituents of medicated cotton and gauzes as well as physical qualifications for absorbent cotton and gauzes. L. H. CHERNOFF.

Beniform. FREYMUTH. *Apoth. Ztg.* 30, 699(1915).—A cryst. powdered mixt. consisting of 60% Ca saccharate and 40% Na citrate, indicated in catarrhal conditions of the intestinal tract. W. O. E.

Glycerol substitutes. C. MANNICH AND F. SCHIRMER. Univ. Goettingen. *Apoth. Ztg.* 30, 713-4(1915).—The following preps. were examd.: (I) Lempellin, a liquid, d₄₀ 1.005, contained a slime-yielding material preserved with boric acid. (II) Dr. Henkel & Co.'s substitute (technical), a thick, colorless, sticky liquid of sweetish taste.

d_{20} 1.21, containing reducing sugars 4.7, sucrose 40.0%. (III) Dr. Henkel & Co.'s (cosmetic), a liquid, d_{20} 1.23, containing reducing sugars 12.6, sucrose 36.8%.

W. O. E.

Enesol. HANS SCHMIDT. *Pharm. Ztg.* 60, 724(1915).—In view of the fact that dil. AcOH ppts. basic Hg salicylate from a soln. of enesol and further that the filtrate therefrom yields on evapn. and boiling with magnesia mixt. methylarsinic acid as the Mg-salt, it appears certain the above prepn. is substantially a mechanical mixt. of the well known Hydragryrum salicylicum and arthenal ($\text{AsO}(\text{ONa})_2\text{Me} + 5\text{H}_2\text{O}$).

W. O. E.

Grass tree gum or acaroid resin as a source of benzoic acid. J. C. UMNEY. *Perfumery Essent. Oil Record* 6, 212(1915).—The resin obtained from *Xanthorrhoea hastilis* yielded from 4.6 to 7.2% of BzOH. When the BzOH is removed by digestion with alkali and the residue is subjected to destructive distn. a heavy acid oil consisting chiefly of phenol is obtained. The resin contains about 1% of a fragrant oil, has some value in perfumery and could be used as a substitute for benzoin, storax and balsam of tolu.

C. O. EWING.

Revision of monographs for the essential oils of the United States Pharmacopoeia. J. C. UMNEY. *Perfumery Essent. Oil Record* 6, 334-7(1915).—Critical comments are given regarding some of the proposed limits for certain of the chem. and physical consts. and other properties of the volatile oils of the forthcoming U. S. P. IX.

C. O. EWING.

"Mercurio coleolo" in antisypilitic therapy. FRANCESCO SIMONELLI. *Rass. clin. terapia, sci. affini.* 14, 329-34(1915).—This is a double oleate of Hg and cholesterol dissolved in oil of sweet almonds. This prepn. of Hg is said to be very effective in both primary and secondary stages of lues, and are better tolerated. D. I. MACHT.

Morphine determination in opium and tinctures. A. HESSELBO. *Archiv Pharm. Chem.* 22, 18-26, 48-55, 74-84(1915).—A critical examn. of the method of Dietrich used in the Pharm. Dan. More accurate results are attained by titrating with 0.1 N acid than by weighing the morphine. The sepn. of the morphine is greatly facilitated by shaking the mixt. Removing coloring matter by means of $\text{Al}(\text{OH})_3$ is apt to cause loss of morphine. Alc. interferes and if present in excess it should be largely removed by evapn. to $\frac{1}{2}$ vol. There is no advantage in using EtOAc as 10 cc. ether will hold all the narcotine present in soln., and the difference in soly. of morphine in these two solvents is insignificant. The amt. of NH_4OH used is very important as an insufficient amt. will not ppt. all the morphine and an excess will cause re-solution of the ppt. One cc. 0.1 N acid is equiv. to 0.0285 g. anhydrous and 0.03003 cryst. morphine.

A. R. ROSE.

Peppermint oil. ALFRED MOHLK. *Archiv Pharm. Chem.* 22, 128-32, 189-92, 241-7(1915).—This oil can be purified by distn. *in vacuo* but this procedure has no advantage over steam distn. M. considers the solubility in 70% alc. as an important test and also recommends combined menthol detn. by the method of Powers and Kleber (U. S. Pharm., 1905). There is no significant relation between the chem. and phys. consts. From the analytical results the following consts. are derived: d_{20} 0.9021, $[\alpha]_D^{19}$ 30.019°; acid no. 0, ether no. 33.8, acetyl no. 186, total menthol 42.3%, combined menthol 9.4%, sol. in 70% alc. 1-2.8%.

A. R. ROSE.

Camphorated chloral. D. E. TSAKALOTOS. *J. pharm. chim.* 12, 355-8(1915); cf. C. A. 3, 2199; 4, 3202; 6, 2240, 2351.—The cryoscopic method was used to det. whether camphorated chloral was simply a mixt. or a mol. compd. Camphor, after recrystn. from petr. ether m. 176°; pure chloral- H_2O m. 51.6 to 51.7°. When increasing amts. of camphor are added to 100% chloral- H_2O , the temps. of solidification of the

mixts. decrease steadily, and their detn. becomes more and more difficult, due to superfusion. At 69.5% of chloral- H_2O , the temp. is 22.0°. Between 69.5 and 42.41%, the melted mixts. are so viscous that no crystn. is possible. At 42.41%, the temp. of solidification is definite again, 28.1°, and steadily increases to 176° as the % of camphor rises. The region of great viscosity indicates the existence of 1 or more compds. of the components.

S. WALDBOTT.

Nor-Camphor. J. CALSEN and R. STÜSSER. U. S., 1,169,316, Jan. 25. *Nor*-Camphor, $C_9H_{16}O$, an oily liquid b. 105°, yielding a semicarbazone, $C_{16}H_{17}N_3O$, m. 167°, forming a soln. with Na salicylate adapted for subcutaneous injection, is formed by boiling and injecting steam into a reaction mixt. of ketopinic acid 10 and 60% H_2SO_4 300 parts at 137–140°, adding Na_2CO_3 to the distillate, extg. with ether, drying, evapg. the ether and distg. *in vacuo*.

Leucocytic extract. R. A. ARCHIBALD. U. S., 1,171,299, Feb. 8. Blood is dild. with 1% citric acid soln. and treated with dil. HOAc to destroy the red corpuscles, the mixt. is centrifuged to ppt. the leucocytes and the ppt. after removal of the supernatant fluid is emulsified by grinding with quartz sand and neutralized with NaOH, mixed with distd. H_2O and heated to 58° for 1 hr. to destroy antiferments. The product is incubated at 37° to effect autodigestion. The resulting liquor is suited for use in treatment of infectious diseases. It may be mixed with tricresol and sterilized at 58° for 1 hr.

Antiseptic therapeutic composition. M. ENGELMANN. U. S., 1,170,056, Feb. 1. Ag phosphate is pptd. on clay which serves as a carrier to extend the surface of the phosphate while retaining its bland, protective and drying action. The mixt. is intended for use as an antiseptic on wounds.

Solid mixture for preparing formaldehyde solutions. G. P. FULLER. U. S., 1,170,624, Feb. 8. A solid polymer of CH_2O is mixed with 0.0005–0.003 of a mol. proportion of Na_2SO_3 or with similar small amts. of other sulfites, hydroxides, carbonates, arsenites, cyanides, borates or phosphates, to form a H_2O -sol. product. Cf. C. A. 9, 2291.

Sodium acetone. G. MERLING, O. CHRZESCUSKI and O. PFEFFER. U. S., 1,169,341, Jan. 25. Na acetone, $NaO.C(CH_3)(CH_2)$, a colorless cryst. compd. stable only below 0°, sol. in ether, forming 3-methylbutinol (a colorless oil b. 105–6°) by reaction with C_2H_2 , is made by mixing $NaNH_2$ 40 with abs. ether 600 parts, cooling to –20°, slowly adding 58 parts of dry acetone while keeping the temp. below –15° and evapg. the ether *in vacuo*. Na ethylmethyl ketone with C_2H_2 yields 3-methylpentinol, b. 120–1°. Na diethyl ketone and C_2H_2 form 3-ethylpentinol, b. 135–7°. Na methyl propyl ketone and C_2H_2 form 3-propylbutinol, b. 137–8° and Na-cyclopentanone and C_2H_2 form the C_5H_9 -carbinol of the formula

Other hydrocarbons may be used instead of C_2H_2 and instead of acetone, EtOAc, methyl ethyl ketone or acetaldehyde may be used to obtain similar compds.

Fermenting sugars. K. DELBRÜCK and K. MEISENBURG. U. S., 1,169,321, Jan. 25. In fermenting sugars with *Bacillus macerans*, *e. g.*, in producing alc. and acetone, a temp. of about 40° is maintained and peat, asbestos or other inert material serving as a distributor of large surface is added to the material undergoing fermentation. The yield of alc. and acetone may be increased 3-fold by addition of the inert carrier.

Alcohol; acetone; cattle food. K. DELBRÜCK. U. S., 1,169,322, Jan. 25. After fermentation of maize, rye, potatoes or oats by action of *Bacillus macerans* the product is distd. to obtain alc. and acetone and the residue is used for cattle feed.

Alcohols. B. S. LACY. Brit., 20,550, Oct. 5, 1914. Alcohols are obtained by the action of basic substances upon alkyl halides in the presence of a liquid, the reacting substances being intimately mixed and heated to over 100° under a pressure exceeding the vapor pressure of the liquid alone. The production of MeOH from MeCl and milk of lime soln. is described in an example; CaCO₃, NaOH, or a mixt. of milk of lime and NaOH or Na₂CO₃, may also be used.

Mononitro- and dinitroaminobenzenearsonic acids or their derivatives substituted in the amino group. C. F. BOHRINGER & SÖHNE. Ger., 285,604, Dec. 25, 1912. These compds. are obtained by reacting upon 4-Cl-3-nitro- or 4-Cl-3,5-dinitrobenzenearsonic acid, with NH₃ or its derivs., and then nitrating the resulting mononitro compds.

High percentage solutions of lecithin in oils and fats. ERBEN DES KARL A. FISCHER. Ger., 286,061, Feb. 2, 1913. Stable mixts. of oils and fats with lecithin, from which the lecithin does not sep. and which contain about 40% lecithin, are obtained by mixing alc. lecithin solns. which are freed by fractional cooling from constituents difficultly sol. in alc., with oils and fats, together with high mol. fatty acids such as oleic acid, and then driving off the alc. by heat. *E. g.*, to 60 parts of a mixt. of 75 parts of olive oil and 25 of oleic acid, are added 80 parts of a 50% alc. lecithin soln., which has been freed from the difficultly sol. portions of the lecithin by fractional cooling. The mixt. is poured upon a flat dish and heated to 50–60° in order to expel the alc. The product contains 40% lecithin. It is not affected by light, and may be preserved for a long time without a sepn. of lecithin. In the 40% lecithin soln. are contained: P 1.66, N 0.78%, and moisture 2.19%.

Dentifrices. F. J. RHODES. Brit., 20,879, Oct. 12, 1914. Dentifrices in powder, paste, or liquid form contain K or other alk. thiocyanate in conjunction with media of a substantially neutral character. A powder dentifrice may consist of 1 part of KSCN, 14 of pptd. chalk, together with essential oil flavorings. Glycerol or tragacanth may be added to this powder to form a paste. For a liquid dentifrice, 1 part of the thiocyanate is dissolved in 7 parts of spirits of wine. KSCN may be formed by digesting together 3 parts of KCN, 6 of H₂O, and 1 of S, and then adding 3 of H₂O and filtering, evapg., and crystallizing.

Dentifrice. F. J. RHODES. U. S., 1,169,998, Feb. 1. KCNS, 5–15%, is added to a neutral dentifrice, formed, *e. g.*, of CaCO₃, glycerol and flavoring, to supply any deficiency of thiocyanate which should be present in the saliva.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Sulfuric acid substitutes. ANON. *Chem. Trade J.* 58, 28(1916).—Owing to the greatly increased demand in England for H₂SO₄ in explosives production, the supply for ordinary manufacturing purposes is greatly below the demand, and expts. have shown the suitability of niter cake as a substitute in connection with various applications in the woolen trade. These include the extn. of grease from suds obtained in scouring, the refining of grease, extg. cotton from mixed rags in the making of shoddy, as well as stripping color from rags, in the latter trade. The cake is dissolved in hot H₂O by the aid of steam, and the soln. used hot. Such a soln. in an equal wt. of H₂O is the equiv. in acid strength of 1/4 the vol. of 60° Bé. H₂SO₄. W. W. WINSHIP.

The decomposition of ammonia. R. PLANK. *Z. ges. Kälteind.* 22, 19-23, 43-6 (1915); *J. Am. Soc. Refrig. Eng.* 2, 34-43 (1915); *Ice and Refrig.* 49, 57-60, 108-10 (1915).—A critical survey of the work and data on this subject is given in order to det. its bearing on (1) the fire and explosion risks in operating NH_3 compression systems and (2) the performance of the system. The decompn. of NH_3 is hindered by lowering the temp. and increasing the pressure, though for kinetic reasons the method of pressure increase may favor decompn. In general, the amts. of non-condensing gases observed are in great excess of what could be expected under the normal operating conditions of temp. and pressure. The amt. of decompn. found in practice is ascribed to the combined action of high temp., rapid compression and the presence of catalysts (iron surfaces) hastening the rate of decompn. No exptl. work is presented. The following precautions are recommended in order to decrease the likelihood of decompn.: (1) Avoidance of high speed in compression. (2) Wet compression; temp. in discharge pipes to be 100° at highest. (3) Cooling of discharge gases by water-jacketing discharge pipe. (4) Lessening catalytic action of surfaces in contact with hot gases by covering inside surfaces of pipe with enamel which is a much poorer catalyzer of the decompn. than iron.
E. C. MCKELVY.

American potash. C. ELSCHNER. *Mining Sci. Press* 112, 155-6 (1916).—A letter describing the exptl. production of K fertilizer salt from natural brines by the Inyo Development Co., at Keeler, Cal. KCl constituting about 4% of the solids of Owens Lake, was formerly wasted in the form of spent H_2O after crystn. of the Na_2CO_3 through evapn. by solar heat. The fertilizer salt produced is a mixt. of the carbonates, sulfates and chlorides of K and Na; it is free from MgCl_2 and MgSO_4 . Recent runs show 29% to 34% KCl. The extn. of K can be done profitably only as a by-product with Na as the main product.
W. W. WINSHIP.

The interrelations of pure and applied chemistry. F. W. CLARKE. *Science* 43, 257-63 (1916).—An address.

The Russian chemical industry and the war. ANON. *Chem. Ztg.* 40, 61-3 (1916).—With a short bibliography.
J. H. MOORE.

Fixation of atmospheric nitrogen (SKERRETT) 4. Potash in certain copper and gold ores (BUTLER) 8.

Rapid crystallization. F. CROTOGINO. *Ger.*, 286,085, Feb. 6, 1913. The crystn. is effected by cooling hot satd. solns. with a current of air passed over them. The passage of air is controlled so that a continuous crystal scum does not form over the surface of the soln.

Aluminium salts from natural silicates. M. F. COOLBAUGH and E. H. QUINNEY. U. S., 1,170,418, Feb. 1. Rocks containing Al silicate and comparatively free from K compds., e. g., kaolin, shales, or clays, are mixed with about 1.7 times as much CaCO_3 as there is SiO_2 present, heated to the temp. of incipient fusion, quickly cooled and leached with dil. H_2SO_4 in the proportion of $3\text{H}_2\text{SO}_4:\text{Al}_2\text{O}_3$. The $\text{Al}_2(\text{SO}_4)_3$ is then crystd.

Dissolving or extracting crude potassium salts. H. DRESCHER. *Ger.*, 286,010, Jan. 17, 1912. The material is treated in the first section of the app., in the same

direction with one solvent, and upon passing to the second section of the app., the first ext. is withdrawn and the material is treated in counter current with another extg. liquid, which is withdrawn separately. The material is preferably treated repeatedly, as specified.

Fluorine compounds of the rare earth metals. GEBR. SIEMENS & Co. Ger., 286,018, May 17, 1913. Addition to 284,889 (C. A. 10, 100). According to the principal process, in certain circumstances, especially with slight acidity and a short period of reaction, a double fluoride of the rare earths and the pptg. agent, especially of Ca, is formed first as an intermediate product. If the reaction is discontinued at this stage, this double fluoride is obtained, and serves as a valuable product. *E. g.*, 11 g. of the crude oxides of the rare earths are dissolved in a small excess of HCl or HNO₃, and the soln. is dild. with H₂O to 100 kg. After the mass has been heated to boiling, 13 kg. of fluorspar are added, and the reaction mass is boiled for about 0.5 hr., *i. e.*, until the pptn. is complete. The product seps. in a granular form, and may be washed out readily. The yield, after drying, is 18.2 kg. of the double fluoride, the theoretical yield being 18.4 kg. The compd. is completely insol. in acid. By the action of solns. of the rare earths on the double compd., the latter is decomposed further with the formation of fluorides of the rare earths.

Ammonium bromide. M. ISSLEB. Ger., 286,183, Apr. 10, 1914. NH₄Br is obtained from end-lyes of the potash industry or from other mother liquors and from coal. The coal used for coking is sprayed with a suitable amt. of the lyes, and coked. The resulting sublimate is combined with the H₂O of condensation, the solns. are evapd. at 60°, the NH₄Cl crystg. out is sepd. from the mother liquor containing Br, and the latter is evapd. at 40° until a crust forms, when 15 times its wt. of 95% alc. is added and allowed to act for 24 hrs. in closed vessels at the ordinary temp. The alc., which contains NH₄Br principally in soln., is distd. off. The NH₄Br, by treatment with soda lye and sepn. of the resulting mixt. of Na salts with 12 times its wt. of 90% alc., can be converted into pure NaBr, which alone goes into soln. and remains as a residue as soon as the alc. is distd. off. If to 100 kg. of coal are added, before coking, 5 kg. of potash end-lyes containing Br, about 3.5 kg. more of H₂O are to be evapd. than when ordinary coal is used, since the end-lyes contain about 30 kg. of solids in 100 kg. Upon coking coal, NH₃ is generated. Other than this, the mother liquors consist of a series of readily sol. salts, with chlorides predominating, but bromides being present also. These chlorides and bromides, especially those of Mg, are readily decompd. upon heating with splitting off of HCl and HBr. Therefore, upon coking coal, NH₄Cl and NH₄Br are doubtless formed, if lyes containing Br are employed to spray the coal. Either a solid sublimate of these NH₄ salts is obtained, or they are found dissolved in the H₂O of condensation. The sublimate is added to the H₂O of condensation in an evaporator, the sublimate is dissolved, and the soln. is evapd. at not above 60° until crystals begin to form. The mother liquor is carefully centrifuged from the crystd. NH₄Cl which is washed with a small amt. of H₂O. The mother liquor contains the readily H₂O-sol. NH₄Br, together with larger amts. of NH₄Cl and other impurities. It is evapd. to dryness in a flat vessel at about 40°, with stirring. The resulting salt crust is transferred to 15 times its wt. of 95% alc., the closed vessel is shaken vigorously, and after 24 hrs. the alc. is filtered off. The residue on the filter is washed again with 2 parts by wt. of 95% alc., the filtrate and washings are united and distd. to recover the NH₄Br which was dissolved in the alc. Crude NH₄Br is obtained as a residue. To obtain pure NH₄Br, the crude salt is treated with soda lye and the resulting mixt. of Na salts is mixed with 12 times its wt. of 90% alc., NaBr alone going into soln. and being obtained pure after distg. off the alc. and recrystg. from H₂O.

Sulfides of aluminium and magnesium. A. LANG. Ger., 285,284, Mar. 31, 1914. Addition to 265,656 (C. A. 8, 1322). Compds. which yield with H_2O pure H_2S are obtained with the aid of a priming mixt. of heavy metal and S. E. g., a mixt. of Al and S is compressed, together with a mixt. of FeS, to bodies which are kindled to form the desired sulfides. Upon the addition of H_2O , the FeS remains unaffected, while the Al and Mg sulfides yield H_2S .

- **Lead arsenate.** E. O. BARSTOW. U. S., 1,169,114, Jan. 25. Pb arsenate is made by reaction, in H_2O , of As_2O_3 and Cl, neutralizing the HCl formed with Na_2CO_3 and adding somewhat less PbO than would be required to combine with all the H_2AsO_4 present.

Formaldehyde-sulfoxylates. H. SPECKETER and E. MARBURG. U. S., 1,169,365, Jan. 25. Alkali metal CH_3O -hyposulfites are reduced to sulfoxylates by the action of electrolytically prepared spongy Zn.

Zirconium carbide and titanium carbide. O. RUFF. Ger., 286,054, July 10, 1914. The corresponding oxides are heated in admixt. with coal or in a carbonizing atm. The carbides of Zr and Ti, because of their great hardness, find application as abrasives, being employed in the form of a fine powder, as uniform as possible, which is used as such or which is formed into stones with binders. By the usual process a molten compact mass is obtained, and this must be powdered before use. The direct production of a fine powder is effected by heating the mixt. to a temp. just below the m. p. of the carbide. E. g., 1 kg. of crude or purified ZrO_2 is mixed with 300 g. coal and heated in a graphite crucible. At a temp. of about 1900° a copious evolution of gas sets in, and continues upon the gradual further increase of the temp., until exhausted. The temp. is raised in this manner to about 2100° . For the manufacture of TiC, a mixt. of 1 kg. rutile and 450 g. coal is heated, at first to about 1300° , and then the temp. is gradually increased as specified above. The fineness of the final product is detd. by the height of the final temp.

Absorbing carbon monoxide. BADISCHE. Brit., 20,616, Oct. 6, 1914. In the sepn. of CO from other gases, by absorption in ammoniacal solns. of Cu_2Cl_2 or other cuprous salt or Cu_2O , the deposition of Cu from the solns. is prevented by introducing O or gas containing O, such as air, into the gas treated, or into the absorbent soln., or into both. Addition of sufficient O also oxidizes the dissolved CO and thereby regenerates the cuprous soln. Cf. C. A. 9, 2801.

Freeing and separating thorium from other rare earths. F. JOSR. Ger., 286,087, Mar. 10, 1914. From the soln. of the phosphates of the rare earths in dil. acids, the Th is pptd. pure, in a single operation, by means of pyrophosphoric acid or its sol. salts, as Th pyrophosphate. E. g., 1000 g. monazite, with a content of 5% ThO_2 is disintegrated, for 6-8 hrs., with 1250 g. concd. H_2SO_4 . After cooling, the mass is transferred to about 10 l. H_2O , and siphoned off from the undecomposed residue. The residue is decanted 2 or 3 times with H_2O , and the H_2O added to the soln. siphoned off. It is then dild. with H_2O until the soln. contains 50-70 g. H_2SO_4 per l. By this dild. the phosphates of the rare earths contained in an av. monazite remain in soln. To this soln. are added with const. stirring 50-60 g. Na pyrophosphate, dissolved in 1 l. H_2O . A fine flocculent ppt. of Th pyrophosphate seps. After some time the supernatant liquid, which contains the phosphates of Ce, La, etc., is siphoned off, and the ppt. is decanted with H_2O , to which 2-3% mineral acid has been added, until the wash H_2O contains only small traces of rare earths. The very pure ppt. of Th pyrophosphate can be converted, after drying, directly into $Th(OH)_4$ by fusion with alkali hydroxide, or it may be dissolved in a mineral acid, and, after conversion into the oxalate, it may be treated with NaOH to obtain the hydroxide; this is suited for further working to the nitrate.

Recovering metals from waste oils. M. E. ROTHBERG. U. S., 1,170,342, Feb.

1. Waste oils carrying metals such as Pb, Sn or Zn (obtained as by-product in plating with these metals) are treated with slightly more mineral acid, *e. g.*, concd. H_2SO_4 , than required to combine with the metal present. Care is taken to proportion the acid so that it does not emulsify the oils and metallic salt soln. formed and the latter is allowed to sep., after agitation of the acid with the oil.

Finely divided alumina-carbon mixtures for manufacture of aluminium. H. F. D. SCHWAHN. U. S., 1,171,360, Feb. 8. $\text{Al}_2(\text{SO}_4)_3$ is heated in a revolving kiln fired with producer or natural gas and the Al_2O_3 produced, mixed with amorphous C from the combustion products, is carried off with the gases from the kiln and collected. The SO_2 formed is also recovered. The Al_2O_3 -C mixt. is used in the production of metallic Al. Cf. C. A. 9, 1227.

Obtaining sulfur from sulfur oxides. W. F. LAMOREAUX. U. S., 1,169,726, Jan. 25. SO_2 or smelter or burner gas is reduced by contact with incandescent C, sufficient heat being supplied to the gas before bringing it into contact with the C to insure practically complete reduction. Heat interchange from the hot gases produced is used for the preliminary heating. Cf. C. A. 9, 1742.

Apparatus for obtaining nitrogen oxides from the air. W. T. HOOFNAGLE. U. S., 1,169,824, Feb. 1. Dried air is fed into an expansion tank 3 through a valve carrying a pointer 5 indicating the rate of flow. It then passes to a reaction chamber which is formed with an outer metal shell 16, a central core 17 of insulating material (fastened to the metal cap 20), a surrounding series of glass tubes 22 positioned close together (closed at the bottom and filled with Hg or acidulated H_2O) and conducting wires 23 leading from the cap into the tubes. A cylindrical metal electrode 26 is fitted

closely within the reaction chamber and carries thin annular ribs 26a with insulating rings 27 between them. When an elec. discharge takes place between the electrodes, the ribs form annular discharging or concentrating points and the arrangement of electrodes forms a rectifying medium for the high tension a. c. used so that the current discharged through the air becomes partly uni-directional. A current of high voltage but small heating effect causes combination of the N and O as air is supplied from the tank 3. Inlet and outlet valves 14 and 15 are controlled by solenoids operating against

springs. The gases formed are passed into an absorber 70 containing dil. HNO_3 and stone or other solid material 79 to break up the gas bubbles.

Electrical insulating composition. F. A. ROBINSON. U. S., 1,170,000, Feb. 1. Elec. insulation is formed on wires, etc., by application of one or more coats of walrus or whale oil which are heated to 500° to harden them. The coating will withstand heating to 650° without carbonizing.

Electric insulating materials. H. GROSSMANN. Brit., 20,409, Oct. 1, 1914. A fusible insulating and filling material for elec. purposes and adapted to be sold in powdered form consists of a mixt. of powdered colophonium and gypsum, preferably in about equal proportions. Powdered paraffin wax may be added in order to render the mixt. less brittle when fused. In this case, suitable proportions are 45% of colophonium, 45% of gypsum, and 10% of paraffin wax.

Waterproofing polished surfaces, porous stone, insulating masses. H. v. D. HEIDE. Ger., 285,967, Feb. 10, 1914. The surfaces are sprayed with an aq. liquid, consisting of ammoniacal Zn soln. and soap. About 60 g. of NH_4 or alkali soap are dissolved in 1 l. of H_2O , if necessary, with the addition of some alc. A soln. of about 8 g. $\text{Zn}(\text{OH})_2$ in 100 g. NH_3 soln. of sp. gr. 0.90, is mixed with 900 cc. H_2O , and the resulting soln. is mixed with the soln. first prepared. The soaps are prepd. preferably from purified oleic acid.

Extruding plastic materials. E. HILLABY. Brit., 20,426, Oct. 1, 1914. A machine for producing sheets, bands, strips, etc., of plastic material of uniform thickness.

Phenol-aldehyde condensation products. F. POLLAK. Brit., 20,977, Oct. 14, 1914. Condensation products, of light color and air and light resistant, are obtained from the sol. intermediate condensation products of phenol and aldehyde which have been made with a minimum quantity of condensing agent, by washing with H_2O and then adding a dil. aq. soln. of a substance adapted to dissolve or oxidize any free phenol present. Suitable substances are alcs., ethers, ketones, aldehydes, hydrated phenols, H_2O_2 , or sugar. The resulting product is washed thoroughly, and the insol. final condensation product is produced in the usual way.

Phonograph records. J. W. AYLSWORTH and E. L. AIKEN. U. S., 1,170,391, Feb. 1. A fusible phenolic resin is dissolved in alc. or other solvent, mixed with $(\text{CH}_3)_4\text{N}_4$ or other reagent which will harden the product on heating, and with an inert filler such as dry wood pulp, the solvent is removed by evapn. and the product after being powdered is molded and heated.

Chewing gum. A. G. MEIER. U. S., 1,171,392, Feb. 8. Chalk is used as a carrier for PhOH , thymol, or an essential oil which is added to chewing gum to flavor it or give it antiseptic properties.

Cylindrical sheet metal filler for absorption and reaction towers. F. RASCHIG. Ger., 286,122, Feb. 6, 1914. The height of these towers is practically the same as their cross section, corresponding to 15 to 20 mm. with a wall of about 1 mm. thickness. The filler elements are simple in construction, offer but slight resistance to the current of gas, and effect an intimate contact between the gas and liquid. In a tower of 1 cu. m. about 300 sq. m. of active surface are contained.

Repairing scored engine cylinders. L. LORENTOWICZ. U. S., 1,169,658, Jan. 25. Scores in cylinders are treated with a flux, e. g., acid and NH_4Cl , filled with Sn and Ag and the filling is shaped to the contour of the cylinder wall.

Stencil fabric. A. E. STRIPPEL. U. S., 1,169,520, Jan. 25. See Ger., 282,433 (C. A. 9, 2298).

Compositions for finger prints. H. JORGENSEN. U. S., 1,170,273, Feb. 1. One surface of a paper blank is treated with a soln. formed of French gelatin 100, Russian gelatin 25, glycerol 25, $K_4FeC_6N_6$ 50 and H_2O 1000 parts, and the fingers are treated with a soln. of $FeCl_3$ 7.5, $Ca(OCl)_2$ 2.5, concd. HCl 10 and H_2O 30 parts and then impressed upon the prepared paper to effect reaction with the coating and develop the finger prints.

"Artificial cork." F. RASCHIG. U. S., 1,170,102, Feb. 1. A composite cork of sp. gr. 0.22 is formed of cork particles agglomerated with a binder of casein or albumin which is hardened *in vacuo* at a max. temp. of $70-80^\circ$ which is gradually reached after continued heating for 4-5 days. This slow hardening and drying avoids rendering the product brittle as in the case of more rapid heating at a higher temp.

19. GLASS AND CERAMICS.

G. H. BARTON, A. V. BLEININGER.

Analyses of excellent window glasses. *Schnurpfel's Rev. Glass Works* 1, 41 (1915). Analyses are given: SiO_2 (a) 71.23, (b) 71.92; Al_2O_3 (a) 1.70, (b) 0.85; MgO (a) 0.20, (b) 0.16; CaO (a) 16.09, (b) 13.65; Na_2O (a) 10.78, (b) 13.42. (a) is more permanent than (b). C. H. KERR.

Window glasses. *Schnurpfel's Rev. Glass Works* 1, 23(1915).—Six formulas are given of German, Austrian and Belgian window glass. C. H. KERR.

Compounds for iridescent glass. *Schnurpfel's Rev. Glass Works* 1, 3(1915).—Six formulas are given. C. H. KERR.

Resists for etching. *Schnurpfel's Rev. Glass Works* 1, 5(1915).—Several formulas are given. C. H. KERR.

Glass etching inks. *Schnurpfel's Rev. Glass Works* 1, 35(1915).—Four formulas are given. C. H. KERR.

Recent researches on siloxide glass. *Schnurpfel's Rev. Glass Works* 1, 3-5 (1915). C. H. KERR.

The continuous drawing and rolling of plate glass. H. J. *Diamant* 37, 545-6, 565-6, 585-6, 605-6(1915), 2 figs.—Two systems are partially described. The glass is ladled from the tank into a pot where it is brought to the required temp. and from which in one system it is drawn in a continuous sheet up an incline through a leer, and in the other is allowed to flow through rollers onto a horizontal table and leer. J. B. PATCH.

A durable silver plate for glass and porcelain. J. P. *Glashütte* 45, 297-8(1915).—A specially prepd. $AgCl$ is mixed into a paste according to 1 of 2 recipes and burned into the surface of the glass or porcelain. Upon this foundation the Ag is plated electrolytically. The ingredients of the paste are $AgCl$ 31, $Pb_2(BO_3)_3$ 3, KNO_3 3, $Na_2B_4O_7$ 1.5; or $AgCl$ 31, $Pb(C_2H_3O_2)_2$ 1.5, Na_2CO_3 1.5, KNO_3 0.4, H_3BO_3 0.4 and $Na_2B_4O_7$ 0.4. Oil is added until a convenient paste is obtained. The $AgCl$ is reduced with Zn and acid, thoroughly washed, dried and kept in the dark. If the acid for the reduction is H_2SO_4 , the first paste is used; if HCl , the second recipe gives better results. J. B. PATCH.

The silvering of glass beads and the working up of the silver residues. J. R. *Glasind.* 26, Nos. 35-36(1915).—Ammoniacal $AgNO_3$ is reduced by milk or grape sugar. The residues are reduced further and the sediment preserved. J. B. PATCH.

Clay for the glass industry. ANON. *Glasind.* 26, Nos. 41-4(1915).—The article deals very briefly with the compn., properties, fusibility, burning and kinds of clay used in European glass factories. J. B. PATCH.

The consumption of fuel in glass works. *Schnurpfeil's Rev. Glass Works* 1, 5 (1915).—In German practice the amt. of coal required to produce 1 lb. of glass melted and ready for use is: 2 lbs. for pots, $1\frac{1}{2}$ lbs. for day tanks, 1 lb. for continuous tanks. Data for other fuels are given. C. H. KERR.

The annealing oven. *Schnurpfeil's Rev. Glass Works* 2, 53(1916).—A drawing and brief description are given of a leer used in Germany and Austria for the annealing of tumblers, chimneys, etc. C. H. KERR.

Flattening stones. *Schnurpfeil's Rev. Glass Works* 1, 23-5(1915).—A standard recipe is: raw fire clay 28, burnt clay 72 (or raw 28, burnt 28, graphite 44). The addition of graphite or talc is recommended. After light burning the stones are polished with a mixt. of 25% each raw and burnt fire clay, Pb_2O_3 and water glass, all finely ground and well rubbed in. C. H. KERR.

Recipes for glass melting pots. *Schnurpfeil's Rev. Glass Works* 1, 41(1915).—Recipes for Belgian, French, English, German and Bohemian clays are given. C. H. KERR.

A hint from enamel technology. SCHWARZBACH. *Diamant* 37, 525-6(1915).—To secure uniformity and complete fusion of the constituents of an enamel the addition of $Na_2B_4O_7$, MgO or NH_4Cl is recommended. J. B. PATCH.

Pennsylvania fire clay. L. C. MORGANROTH. *Bull. Am. Inst. Mining Eng.* 1916, 475-81.—Geologically the most important Penn. clays are from the Pottsville Conglomerate Series. Some of the Upper Coal Measures are also very important. C. H. KERR.

A comparison of some kaolins in respect to size of grain. CHARLES F. BINNS. N. Y. State School of Clayworking and Ceramics. *Trans. Am. Ceram. Soc.* 17, 356-72 (1915).—In addition to the 3 original cans of the Schultze app. (5.0, 7.5 and 13.5 cm. diam.) 2 more were added (21.5 and 30.0 cm. diam.). The velocity of the H_2O was, resp., 1.5, 0.7, 0.18, 0.08 and 0.04 mm. per sec. Eng., Ger. and Georgia clays are very similar in size of grain. Some of the Eng. clays usually considered of less than first quality show rather large contents of coarse grains. N. Carolina clays showed large excess of coarse grains. C. H. KERR.

The electrical conductivity of a porcelain mixture and a shale upon heating. CHAS. S. KINNISON. U. S. Bureau of Standards, Pittsburgh. *Trans. Am. Ceram. Soc.* 17, 422-31(1915).—Test pieces $\frac{9}{16}$ in. diam. $\times \frac{3}{4}$ in. long were made from a typical porcelain mixt. and from Bedford shale, Pt disk electrodes being imbedded in each end, the distance between electrodes being $\frac{1}{4}$ in. The temp. was increased 1° per min. to 1400° for the porcelain and 1150° for the shale. During the heating up the elec. cond. was measured by a Wheatstone bridge set. Sources of error were: (1) formation of gas blebs; (2) possible difference in temp. between furnace and specimen; (3) shortening of the specimen during the test. Before vitrification starts conduction is by electrons, during incipient vitrification it is partly by ionization; and after passing the softening point of the principle composite eutectic conduction is due mostly perhaps to the ions. With the porcelain body the resistance changed rapidly from 100,000 ohms at 975° to 15,000 at 1050° and then more gradually to 2000 at 1150° and finally very slowly to 1000 at 1325° . The Bedford shale resistance changed rapidly from 90,000 ohms at 875° to 12,000 ohms at 950° , then more gradually to 2000 ohms at 1050° and finally very slowly to 1000 ohms at 1150° . Changes in the curves from rapid to slow decrease in cond. with temp. increase shows the change from solid to liquid condition. The results show that these silicates behave as electrolytes and show ~~disagreement~~ ^{disagreement}. A molten condition is not essential to the presence of ions since ~~polymers~~ ^{polymers} ~~can be~~ ^{can be}

noted much below the m. p. Large differences in cond. are due more to the speed with which ions are permitted to travel than to change in ionic concn. C. H. K.

System calcium oxide, aluminium oxide, magnesium oxide (RANKIN) 6. Chemistry of amorphous solids (LEWIS) 2. Artificial insulating materials 4.

Coloring glass. H. ROSENTHAL. U. S., 1,169,571, Jan. 25. Glass for use in eye glass lenses is tinted by exposure at close range to rays from an X-ray tube. The same effect is produced in 6-24 hrs. as by exposure to sunlight for 10-20 yrs.

Color screens. E. J. BRADY. Brit., 20,827, Oct. 10, 1914. Color screens for artificially producing daylight comprize a single homogeneous glass containing Ni and Cu or Co, or both. Potash-lime glass is preferably used. The glass is used for elec. light bulbs and shades.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Rational production of portland cement. F. FERRARI. Livorino. *Ann. chim. applicata* 4, 329-41(1915).—F., assuming x = hydraulic modulus = $\text{SiO}_2/\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$, and y = index of clay = $\text{CaO}/\text{SiO}_2 + \text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$, develops the formula $y = -2.5x + 7.5$ as the expression of a rational law of portland cement burning—"Facility of burning and value of the clinkers are proportional." The typical compn. of cement and easy burning are reached when $x = 2$ and $y = 2.5$. The mix formed according to these factors burns with easy handling of the furnace, gives homogeneous granulation, equal and complete scorification of clinkers, which are hard, heavy, brown, strongly refracting, does not expand on discharging from the furnace, and is of slow set. Unburned or fused particles are absent. There is the normal, const. thickness of material covering the refractory in the zone of scorification. Departure from the above calcd. values of x and y gives undesirable conditions of burning and poor clinkers.

S. LEVY.

The incomplete hydration of cement. N. C. JOHNSON. *Am. Gas Light J.* 103, 283(1915); see C. A. 9, 1380.

A. J. PHILLIPS.

Some fallacies in cement testing. W. L. GADD. *Concrete Inst. London* 5; *J. Am. Soc. Mech. Eng.* 37, 487-8(1915).—Cement stored in sacks may become either slow- or quick-setting and no relation was found in the setting time of this material compared with cement aerated in thin layers for 24 hrs. before testing. Pure dry air was found not to affect the setting time; moist air free from CO_2 had a distinctly retarding effect although only a trace of moisture was absorbed and air containing CO_2 had an accelerating effect. Attention is called to the fact that the size of sieves is not generally specified; with the same wt. of cement a large sieve is more effective than a small one. G. rejects the possibility that there is free CaO in cement and considers that unsoundness is due to the presence of an abnormal silicate which disintegrates with increase in vol.

A. J. PHILLIPS.

Lutes and cements. S. S. SADTLER. *Met. Chem. Eng.* 14, 197-200(1915).—A classification of formulas according to compn. and use in the following divisions: Water-, oil-, acid- and chlorine-proof, plaster of Paris cements, marine glue, gasket compns., machinists', leather- and Fe-cements, MgO compns. and oxy-chloride cements.

A. J. PHILLIPS.

Testing and handling cement aggregates. H. S. MATTIMORE. *Cement World* 8, No. 12, 40-1(1915).—Field tests have shown that it is not advisable to replace all

sand by screenings. The voids are detd. by placing sand loosely compacted in a cylinder which has a hole drilled in the bottom through which a tube leads to a buret filled with H_2O . This app. is so placed that gravity causes the H_2O to rise slowly and thus eliminates the formation of air pockets. By reading from the buret the vol. of H_2O that has flowed out, an accurate result may be obtained. Cf. *C. A.* 9, 853.

R. L. SIBLEY.

The use of gas tar and coal tar on concrete subjected to high velocities of water. C. H. PAUL. *Reclamation Record*, Jan. 1916; through *Eng. Contr.* 45, 56(1916).—The regulating outlets through the Arrow Rock Dam are painted with 2 coats of thin water-gas-tar, followed by 2 coats of coal tar, a better bond thus being obtained. This practice is not so much for waterproofing as to fill all voids and prevent erosion caused by formation of a vacuum in small voids or pockets.

A. J. PHILLIPS.

Battery-room floors impervious to acid 4.

Lime and cement kilns. H. WALKER. *Brit.*, 20,972, Oct. 14, 1916. In a process of calcining lime or cement in a shaft kiln of the kind in which the calcining zone is situated at a considerable distance above the bottom of the kiln, the charge is kept moving and continuously discharged by mechanically driven rocking or rotating breaking and agitating bars.

Impregnating and improving woods. F. HASSELMANN. *Ger.*, 286,115, May 28, 1908. The process is suitable as well for the treatment of freshly cut as for seasoned pine and also other common woods such as beech wood and the like, which thereby acquire beautiful and characteristic colorings suiting them for ornamental purposes. The wood is heated for 2 to 5 hrs. in an aq. soln. of $FeCl_3$, $NH_4Al(SO_4)_3$ and $MgCl_2$, heated to 80–100° and stirred constantly, and then allowed to cool in the liquor without stirring. The lye consists preferably of 1.5% $FeCl_3$, about 2% $NH_4Al(SO_4)_3$, and 1.5–2% $MgCl_2$, and is used in an av. concn. of 5%. After cooling in the lye, the wood is dried carefully. During the drying the chem. reaction is said to be completed, so that the wood becomes resistant to extn. According to the amt. of the materials used, the wood acquires a silver gray, yellow, or brown color. If white ants, borers, or the like are to be excluded, schoenite ($MgSO_4 \cdot K_2SO_4 + 6H_2O$) is also added to the lye. The wood is fireproofed, to an extent, by the addition of KCl .

Impregnating and coloring wood. C. H. SHATTUCK. U. S., 1,169,289, Jan. 25. Wood is treated with the acid liquors from the destructive distn. of wood, under gradually increasing temp. and pressure, to give the wood a dark color and remove gums and resins.

Preserving wood. J. P. é ICAZA. U. S., 1,169,349, Jan. 25. Wood is impregnated with a soln. of $MgCl_2$ of a d. of at least 15° Bé. and is then given a H_2O -resisting coating by application of a sol. silicate which reacts to form Mg silicate.

Wall covering from slag. S. W. OSGOOD. U. S., 1,169,506, Jan. 25. A finely divided colored mineral ingredient for use in coatings for walls, tarred roofing paper, shingles, etc., is prepared by running molten slag into a soln. of Na or K silicate, to which coloring materials or a hardening agent (e. g., Al , Ca or Mg -silicate or sulfate) may be added.

Paving composition. E. A. PATERSON. U. S., 1,171,236, Feb. 8. A paving mixt. is formed of road metal mixed with powdered $CaCO_3$, asphalt and sol. silicate containing a relatively low % of combined H_2O .

Artificial stone. P. KUHN. U. S., 1,170,499, Feb. 1. Plaster of Paris 6, is mixed with portland cement 6, $MgCO_3$ 1, ashes 4, wood shavings 12, and H_2O 16 parts.

Artificial stone. W. W. BREBB and E. E. DAVIS. U. S., 1,170,038, Feb. 1. A dry mixt. is formed of crushed pumice 1.5, gypsum 1.5 and portland cement 1 part and each cu. ft. of this mixt. is mixed with 10 gals. of a 1% NH_4Cl soln.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Fuel values. J. H. PATTERSON. *J. Soc. Chem. Ind.* 35, 10-2(1916); *Colliery Guardian* 111, 132-3(1916).—The value of a fuel must be measured by the amt. of heat that can be obtained from that fuel by the expenditure of a definite amt. of money, and the number of thermal units (B. t. u.) per penny is designated as the abs. heat value. P. compares various fuels on this basis and gives as the values under 1915 conditions, (1) town gas 27,000; (2) oil fuel 29,000; (3) foundry coke 70,000; (4) coal powder 107,300; (5) producer gas 110,600; (6) washed coal 126,000; (7) coke breeze 200,000.

H. L. OLIN.

The coals of Brazil. I. C. WHITE. *J. Ind. Eng. Chem.* 8, 195(1916).—The Permian coals of South Brazil whose field covers several hundred square miles contain about 35% of ash, of which 2-8% is S. Crushing, washing and briquetting processes reduce the ash of 33% of the coal to 14% and raise the heat value to 13,500 B. t. u. About 42% of the output is slack carrying 25% ash. The lignite of areas of North Brazil are unmapped but promising.

H. L. OLIN.

Utilization of peat. ANON. *Electrician* 76, 658(1916).—The Wiesmoor power station uses peat as fuel and supplies energy to Wilhelmshafen and 6 other towns. The plant has been in operation since 1909. There are 3 turbo-generators of 1250 kw. capacity each. 75 tons of peat are consumed per day. The calorific value of the peat briquets is 5400 B. t. u.

C. G. F.

"Natalite," a motor fuel consisting of alcohol and ether made from molasses. ANON. *Intern. Sugar J.* 18, 32-3(1916).—Claims are made that this product is the equal of petrol.

A. GROSS.

The formulas for the indirect analysis of generator gas. FRITZ HOFFMANN. Berndorf. *Chem. Ztg.* 40, 81-2(1916); see *C. A.* 10, 266.

J. H. MOORE.

Gas-producer for steam raising. E. C. MILLS. *J. Soc. Chem. Ind.* 34, 1001-2 (1915).—The Mills producer is a movable structure mounted on rollers and set immediately opposite the furnace, from which the ordinary boiler-grate is removed. The air used in the gas combustion under the boiler is preheated by being drawn through a jacket surrounding the producer, loss of radiant heat being thereby prevented. Comparative tests on a Cornish boiler showed the new process to be 50% more efficient than hand firing.

H. L. OLIN.

Effect of atmospheric conditions on light given by Hefner lamp. E. OTT. *Gas World* 63, 493-5(1915); *Electrician* 76, 227-8(1915).—Expts. were made to det. the decrease in illuminating power of a Hefner lamp due to decreasing partial pressure of O_2 in the air. The supply of O_2 was varied by changing the pressure of the air supplied and also the CO_2 and aqueous vapor content of the latter. By reducing the air pressure from 800 mm. to 700 mm., the light from the lamp decreased 1%; while by reducing from 700 mm. to 600 mm. the illuminating power fell off about 7%. Formulas are given expressing the change in illuminating power of the Hefner lamp with change in altitude (i. e., partial pressure of O_2).

F. L. GROVER.

Copper sulfate method of determining iron in powdered coke. J. R. CAMPBELL. *Chem. Analyst* 15, 13(1915).—Weigh 5 g. powdered coke sample into a No. 2 beaker.

add 75 cc. CuSO_4 soln. (2%), boil for 10 min., filter and wash. Acidify the filtrate with HCl , oxidize with HNO_3 , ppt. and reppt. to remove traces of Cu salts. Dissolve final ppt. in HCl and det. Fe with KMnO_4 or $\text{K}_2\text{Cr}_2\text{O}_7$. Calc. to Fe_2O_3 and deduct from apparent ash to give true ash. A blank detn. for the purpose of correction should also be run. Powdered samples frequently contain Fe coming from the mortar or steel pulverizing app. This can be shown by making comparative analysis on a duplicate specimen using an agate mortar in its prepn. H. M. LANCASTER.

Modern development in the combustion of blast-furnace gas with special reference to the Bradshaw gas burner (HEUSSENER) 9. Petroleum and natural gas resources of Canada (CLAPP) 8. Rhode Island coal (ASHLEY) 8.

Composition fuel. W. T. VINT and S. G. GRIMSHAW. Brit., 20,625, Oct. 6, 1914. Canna root is used as a binder in conjunction with a waterproofing material such as pitch in briquetting coal or other fuel. Preferably, a mixt. in equal proportions of anthracite and dry steam and bituminous coals amounting to 94 parts is mixed with 4 parts of ground pitch; about 2 parts of canna roots are then added, either dry and ground, with subsequent heating in a sep. mill by the admission of steam until the mass is cooked, or in the form of a pulp which is injected with high-pressure steam, less of the canna root being required in the latter case.

Making coal briquets. E. R. SUTCLIFFE, J. H. PHILLIPS and D. A. THOMAS. Brit., 20,679, Oct. 7, 1914. The raw material is powdered so as to pass through a 200 mesh, and with or without a binder is subjected to high pressures (reaching 10 tons per sq. in.) in a completely enclosed mold space permitting of the transverse expansion of the block or briquet under the internal stresses created as a result of the compression.

Furnaces. R. F. HISLOP and G. R. HISLOP. Brit., 20,929, Oct. 13, 1914. In a gas furnace for heating metal sheets and of the kind comprizing a gas-producer supplying gas to a combustion chamber where it is mixed with air before entering the heating chamber, the gas-producer, combustion chamber, and heating chamber are so arranged with regard to one another that the gas in passing from the producer to the heating chamber travels horizontally and is twice deflected at right angles.

Retort furnaces. S. N. WELLINGTON. Brit., 20,457, Oct. 2, 1914. Vertical retort furnace for the destructive distn. of coal, etc., of the kind in which the retorts are situated between series of horizontal heating flues connected together in pairs and to gas and air supply conduits in such a manner that the direction of flow of the heating gases can be reversed through the pairs of flues.

Continuous analysis of gas. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger., 285,781, May 30, 1914. The gas under examn. is brought into contact with the reagent, and the thermal change is measured by thermo elements. The cold junction is kept at the same temp. as the reagent liquid and the gas to be analyzed.

Determining the benzene content of gases. J. H. REINEKE. Ger., 285,920, June 24, 1914. The method is dependent upon the illuminating power of a flame regularly supplied with the gas under examn., which is detd. with the aid of a Se cell, or the like, and a galvanometer. As expts. have shown, the illuminating power of the gas carrying the C_6H_6 is found to be so small that in all cases it may be disregarded.

Gas-producer. J. E. BELL. U. S., 1,170,496, Feb. 1.

Vertical retort for producing coal-gas. A. McD. DUCKHAM. U. S., 1,171,183, Feb. 8.

Apparatus for cooling and removing heavy hydrocarbons from coal gas. H. A. CARPENTER and A. W. WARNER. U. S., 1,169,615, Jan. 25.

Washing gas. H. A. BRASSERT. U. S., 1,169,764, Feb. 1. Gas is passed successively through coarse and fine sprays, vertically, and is then led over baffles to remove entrained H_2O .

Gas-washing tower. H. A. BRASSERT and C. J. BACON. U. S., 1,169,765, Feb. 1.

Gas-washer. H. A. BRASSERT. U. S., 1,169,766, Feb. 1.

Gas-scrubber. H. A. CARPENTER. U. S., 1,170,510, Feb. 8.

Isoquinoline. GES. FÜR TREERVERWERTUNG. Ger., 285,666, Jan. 29, 1914. Crude isoquinoline of coal tar serves as the initial material.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Oil refining. F. E. KNOCH. *Oildom* 6, 63-5(1916).—A general description and discussion. F. W. SMITHER.

European refining methods. L. SEULENFRIED. *Oildom* 6, 66-7(1916).—A general description (with a chart) of the methods of refining paraffin-base crude oil in Central Europe (Austro-Hungarian and Roumanian fields). F. W. SMITHER.

Report on switch and transformer oils. Sludge formation. P. DIGBY. *J. Inst. Elec. Eng.* 53, 146-56(1915).—250 cc. of oil are placed in a long-neck 500 cc. flask closed by a stopper and fitted with a glass tube extending to the bottom of the flask and a short tube connected to a suction pump. O_2 is drawn through the oil in presence of finely divided Cu and Fe, with the flask set in the oil bath and kept at 138° . The test requires 14 hrs. The flask is cooled and the sludge formed measured. A standard for dry oil is based on dielec. strength and sp. resistance; a small amt. of moisture reduces the 2 enormously. Thermal transference = $k(f)$ (coeff. of expansion)/ (f) (viscosity) with viscosity expressed as Redwood, Saybolt, or Engler units. The greater the sp. gr. and viscosity, the greater the % C formed by arcing in oil. Analysis is given. All products are considered the result of oxidation with the formation of complex organic acids, dehydrogenated hydrocarbons, and oxidized resinous asphaltenes. Some manufacturers consider sludging a purely chem. reaction between unsatd. hydrocarbons and O_2 of the air and design transformers to minimize the surface exposed, or cover it with an inert gas. W. H. BOYNTON.

Report of committee D-2 on standard tests for lubricants. *Proc. Am. Soc. Testing Materials* 15, I, 273-83(1915).—Viscosity: Saybolt Universal viscosimeter is proposed, the temp. being 100° , 130° or 210° F. according to the nature of the oil. Sp. gr.: Geissler pycnometer is proposed, but the statement is made that for fluid lubricants a Westphal balance or a hydrometer gives sufficiently accurate results. Free acid: Oil is treated with EtOH and titrated with $N/6$ KOH. Cloud and pour tests: Oil is first heated to 75° F. For cloud test oil is cooled and the temp. at which the lower half of the sample is opaque is noted. For pour test oil is cooled and at each drop of 5° F. it is noted whether the oil will flow. The reading previous to the congealing temp. is called the "pour test." Minority reports which adversely criticize some portions of the majority report are given. A long discussion (pp. 295-324) relates mainly to viscosity. E. W. BOUGHTON.

The turpentine industry in the Southern States. CHARLES H. HERTY. Univ. N. Carolina. *J. Franklin Inst.* 181, 339-67(1916).—The evolution is traced of the modern procedure for the collection of the oleoresin by means of gutters and cups. This pro-

cedure produces a larger yield of turpentine and of rosin than does the old "box" method and is less destructive to the trees. The distn. of the gum is described. Also in *Chem. Eng.* 23, 95-102(1916).

JOSEPH S. HEPBURN.

Petroleum resources of Canada (CLAPP) 8.

Fractional distillation of petroleum or tar oils in vacuo. L. STEINSCHNEIDER. *Ger.*, 285,969, Apr. 15, 1913.

Crude-oil preheater for oil stills. P. PORGES, R. NEUMANN and G. GLASS. *Ger.*, 286,024, Jan. 30, 1914. An app. is specified whereby the heat contained in the distillates is utilized for preheating the crude oil.

Destructive distillation of wood. T. W. PRITCHARD. *Brit.*, 20,867, Oct. 12, 1914. A process of distn. consists in charging the retort with wood or other solid material in such a manner that a space for the circulation of gases is left between the charge and the wall of the retort, replacing the air in the retort by a non-supporter of combustion, such as CO₂ or coal gas, heating the retort, and equalizing the temp. throughout the charge by withdrawing the gases and vapors generated from the lower part of the retort and re-introducing them into the upper part.

Destructive distillation of wood. L. HANSON. U. S., 1,169,956, Feb. 1. Oil is distd. from wood by quickly heating in a retort to a temp. above 340° and injecting superheated steam into the retort at a temp. above 340° to mix with the vapors distd. from the wood and carry off the vapors, which are led to a condenser.

Recovering turpentine from wood. W. K. FREEMAN. U. S., 1,169,325, Jan. 25. Blocks, chips or finely divided long leaf pine or other resinous wood are placed in a closed digester and the air is expelled by H. Then a soln. of fiber-liberating material is run in at the bottom of the digester to force the gas out and steam is admitted to heat the contents of the digester and vaporize the oil. Part of the cooking soln. is circulated through the digester, a separator and the steam generator and the vapors are drawn off from the soln. and H₂O and oil are condensed and sepd. from each other.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Utilization of wood waste. ARTHUR D. LITTLE. *Mel. Chem. Eng.* 14, 133-5 (1916); *J. Ind. Eng. Chem.* 8, 102(1916); *Chem. Eng.* 23, 83-6(1916).—Large scale measurements of longleaf pine mill waste and logging waste show that 1/3 of the wood in the tree is wasted. The annual total waste is thus very large. Much of this waste is available for utilization for paper, alc., etc., and advance in this direction is urged. Data on the principal characteristics of longleaf pine are given. V. NUNEZ.

The celluloid industry and its economic importance. F. PLATE. *L'Industria* 29, 346, 364, 380(1915). S. LEVY.

Preparation of celluloid using the bast celluloses of mitsumata and mulberry as raw materials. HIROTARO NISHIDA. *Kogyo-Kwagaku Zasshi* 18, No. 210, 18-25 (1915).—Yields and analytical consts. of cellulose nitrate prepd. from unsized tissue papers made from *mitsumata* and from mulberry fibers are given. Nitration products from *mitsumata* are of good quality but yields are lower than for cotton. Results from mulberry are fairly good. V. NUNEZ.

Cellulose esters. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BALE. *Brit.*, 21,016, Oct. 15, 1914. Cellulose fatty-acid esters, consisting of glass-like jellies and

giving very viscous solns., are prepd. by treating cellulose at a temp. not above 200° with Ac_2O or other fatty-acid anhydride, dild. or not with glacial HOAc , in the presence of feebly acting catalysts, until a solid jelly is obtained without liquefaction of the mixt. The esters obtained may be converted into others showing different soly., by treatment of their solns. in suitable solvents such as phenols, cresols, or tetrachloroethane, with hydrolytic agents, or by heating such solns. In examples, cellulose or feebly nitrated cellulose is treated at a temp. below 20° with AcOAc , glacial HOAc , and SO_2Cl_2 or a mixt. of ZnCl_2 and PCl_5 , and the glass-like mass obtained dissolved in tetrachloroethane and converted into acetates by heating, after the addition of NaOAc to neutralize the SO_2Cl_2 .

Dyeing nitrocellulose. FARBW. v. M. L. & B. Ger., 285,323, Feb. 4, 1914. To the nitrocellulose solns. are added substances which, with or without the addition of catalyzers or oxidizing agents, produce, by subsequent oxidation, the desired color. E. g., *p*-hydroxyphenyl-*p*-aminotolylamine 5, and zapon varnish 100 are dissolved, and small traces of CuCl_2 , dissolved in alc., are added.

Wood-pulp from resinous woods. J. ARTSCHOURIN. U. S., 1,169,592, Jan. 25. Brown wood pulp is obtained from resinous wood by treating the wood with a soln. of alkali of 4-7° Bé. at a temp. of about 100° (this soln. being too dil. to decompose the incrusting substances of the wood), under a pressure of 3-5 atm. and after drawing off the soln. and sepg. the resinous materials from it the wood is again treated with the same soln. and simultaneously with steam under 5-6 atms. pressure.

Wood-pulp for paper. C. BACHS-WÜG. U. S., 1,169,597, Jan. 25. Wood blocks in a digester are exhausted of air, impregnated with SO_2 to bleach and soften the outer portions of the blocks and then cooked in a NaCl soln. and ground.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Trinitrotoluene. M. COPISAROW. *Chem. News* 112, 247-8(1915); cf. following abstract.—Six isomers of trinitrotoluene are known: α -, 2, 4, 6, m. 80.8°; β -, 2, 3, 4, m. 112°; γ -, 2, 4, 5, m. 104°; δ -, 3, 4, 5, m. 137.5°; ϵ -, 2, 3, 5, m. 97.2°; ζ -, 2, 3, 6, m. 79.5°. Com. trinitrotoluene, while principally the α -form, is accompanied by other modifications, produced from *m*-nitrotoluene, which constitute about 4.5% of the com. mononitrotoluene. All of the isomers of trinitrotoluene are of practically the same value as explosives. They may be distinguished by acetone and NH_3 with which the α -form gives deep red, β -form greenish yellow, γ -form blue, ϵ -form rose-red and the ζ -form orange-red. The manuf. of trinitrotoluene is usually carried out in 2 or 3 stages, the concn. of acids being gradually increased, and although by itself a simple process, numerous chem. and technical difficulties are met with when the manuf. is conducted on a large scale. Chief among these is the presence in the product of inorganic impurities derived from Pb compds. in the acids or from the action of the acids on the app. in which the nitration is carried out, and of organic intermediate compds. and by-products due to imperfect stirring, to concn. and ratio of acid and to duration and temp. of reaction. A check on the operation may be found in the appearance and analysis of the spent acid which varies in color from yellowish to dark brown, the color being the darker the less the nitric and the more the sulfonic acids, as well as organic matter, present. The mineral matter present during the process may act either as a catalyst or a chem. reagent. When the mineral acids act upon the metal parts of the app. H may be set free and it may reduce some of the nitro compds. Under the working conditions amino groups may be diazotized yielding cresols and nitrocresols whose salts are highly sensitive

explosives and thus there may be obtained as by-products: (1) trinitrobenzoic acid, and even tetranitromethane, owing to oxidation in case of overheating or pressure. The intense odor of the latter is sometimes observed in the factories, but the former, owing to its solubility, generally escapes detection; (2) phenolic compds., like cresols, owing to the reduction of some of the nitro compds.; (3) sulfonic acids, when the quantity of nitric in the mixed acid is below the minimum. In the process of manuf. of trinitrotoluene the following must be observed: (1) The amt. of HNO_3 to be used must exceed at least by $\frac{1}{2}$ mol. the quantity theoretically required for the carrying out of the nitration to a certain stage. (2) The extent of nitration should be regulated more by the concn. of the acids, temp., and duration of reaction than by the actual quantity of HNO_3 present. (3) The reaction product should not be kept in contact with the spent acid longer than is really unavoidable. (4) The concn. of acid and material of plant should be such as to reduce their action on one another to a minimum. (5) The starting materials (toluene and acids) must be pure. The residue from the mother-liquors consists of a complex mixt. of various di- and trinitrotoluenes. By nitrating this with a mixed acid containing only 15% of HNO_3 a "liquid trinitrotoluene" is obtained, which has considerable power, and has the property of gelatinizing collodion cotton, as nitroglycerin does. It is used in the manuf. of gelatinized explosives. It contains 16.6 to 17.2% of N, whereas pure trinitrotoluene contains 18.5% and dinitrotoluene 15.4%. Other details of importance to manufacturers and users of trinitrotoluene are set forth.

CHARLES E. MUNROE.

The purification of trinitrotoluene. M. COPISAROW. *Chem. News* 113, 37-8 (1916); cf. C. A. 10, p. 527 and preceding abstract.—The purification is largely limited to removal of acid and volatile matter since mineral matter and intermediate and by-products are present only in very small quantities. Acid is removed by agitating the molten trinitrotoluene several times with hot water. Long exposure must be avoided because (1) trinitrotoluene is somewhat volatile in steam, (this vapor is the source of the bitter taste observed in the washing department; it may cause headache and even sickness, and (2), a side reaction may set in with the formation of dinitro-cresols in a manner similar to the formation of dinitrohydroxybenzoic acids from trinitrobenzoic acids. The use of alkalis for neutralization of the acid is not permissible. Even NaHCO_3 may give rise to dangerous Na salts of phenolic by-products. Volatile matter (moisture) can be removed by keeping the trinitrotoluene at 95–100° for several hrs. The purification of a crude product containing a comparatively high % of mineral matter and org. by-products is a somewhat more complicated problem. The most radical way in such a case is to recrystallize the crude product from alc. or toluene (in the latter case the mother liquor from the crystn. can be transferred directly to the nitrating plant), thus removing practically all impurities. The second method consists in treating the crude product with H_2SO_4 , HNO_3 , or H_2SO_4 with an addition of about 5% of HNO_3 . The use of H_2SO_4 is based on the fact that trinitrotoluene is not easily attacked by concd. H_2SO_4 , in which it is fairly sol. at 90–100°, sepg. unchanged, on cooling or diln., while most of the impurities are sulfonated. A little HNO_3 added to the H_2SO_4 prevent the substitution of NO_2 by SO_3H and the partial oxidation of org. impurities. It is not advisable to lower sp. gr. on diln. below 1.2 as: (1) A fairly high concn. prevents some of the org. impurities from sepg. out with the trinitrotoluene. (2) It makes easier the subsequent reuse or concn. of the acid. (3) The solubility of trinitrotoluene in acid does not decrease on further diln. Extended data and a chart relative to the acidity of different samples of trinitrotoluene are given and it is stated that even pure α -trinitrotoluene (re-crystd. from acetone and then from alc.), melting at 80.7°, was found to be not quite neutral. C_1 attributes the acidity to phenolic rather than acid compds.

CHARLES E. MUNROE.

Preparation of trinitrotoluene. M. GIUA. *L'industria* 29, 507(1915); through *Ann. chim. applicata* 4, 363.—Symmetrical trinitrotoluene is generally produced by the action of HNO_3 on toluene. It crystallizes in white needles that turn yellow in the air and m. 80.6° . It may be distd. without alteration. Heated above 240° it burns without deflagration. It does not explode by impact; a Hg fulminate is necessary. G. studied the conditions that ought to be observed in nitrating to obtain the best yield and purest product. S. LEVY.

Explosion of a nitrotoluene still. Board of Trade, Marine Dept., Dec. 1915; *J. Soc. Chem. Ind.* 35, 143.—A "steam" explosion occurred due to fracture of inside coil. CHARLES E. MUNROE.

Proximate analysis of nitrocellulose solutions and solvents. A. D. CONLEY. *J. Ind. Eng. Chem.* 7, 882-7(1915).—C. enumerates in detail the constituents of nitrocellulose solns., particularly those in commercial use and describes the uses of such solns. Methods are given for detg. nitrocellulose in these solns. by pptn. with CHCl_3 ,* for detg. resins and oils and for sepg. and detg. the various solvents, including Hoffman's diacetone alcohol ("Alco. Deo."). The character of flash points and the effects on it of different solvents and viscosity and its detn. are discussed. C. E. MUNROE.

The manonitrometer for the titration of gun-cotton powders, nitration acids and other substances containing nitrogen. V. PLANCHON. *Ann. chim. anal.* 20, 189-97 (1915).—The app. employed differs from nitrometers of the well-known Lunge type in that the reaction between the Hg, H_2SO_4 , and nitric ester is carried out in a vacuum in a flask attached to a manometer and that volumes as great as 50 cc. of 95% H_2SO_4 are employed. It is claimed that the manonitrometer is more precise because the pressure exerted on the gas in the nitrometer causes secondary reactions to occur between the N oxides and H_2SO_4 which gives rise to errors in readings. Also in *Z. ges. Schiess- und Sprengstoffw.* 11, 22-4(1916). CHARLES E. MUNROE.

Limits of inflammability of mixtures of methane and air. G. A. BURRELL AND C. G. OBEREFL. Dept. Interior, Bur. Mines, *Tech. Paper* 119, 27 pp.(1915).—The smallest proportion of CH_4 with air which permitted self-propagation of flame when ignited from bottom by flash from 7 amp. at 220 v. in a box $5\frac{3}{4}$ ft. high and $5\frac{3}{4}$ cu. ft. capacity with a paper diaphragm for vent at top was 4.9%; on ignition at top it was between 5.7 and 5.8%. With the diaphragm at the bottom and box vertical 5.4-5.5%; with box on side, 5.5-5.6%; with 2800 cc. vessel 12 in. high by 5 wide, ignition at top, 5%; hempel pipet, ignition at top, 5.5-5.6%, iron pipe 7 ft. long, 12 in. diam., ignition at top, 13.4-13.9%, ignition at bottom, 15-15.4%; hempel buret with small spark from induction cell 12.4-13.2%. Clements' results on effects of changes in O and CO_2 contents on limit of inflammability are reviewed (*C. A.* 7, 3840). C. E. M.

Notes on the ignition of explosive gas mixtures by electric sparks. J. D. MORGAN. *Electrician* 76, 536-8(1916).—From expts. M. concludes that it is necessary to distinguish between the energy that produces the spark and the "incendivity" and that a measure of one is not a measure of the other except when other physical conditions are kept const. Ignition seems to depend upon the ionization caused by the spark. Experiments on the effect of adjustments and voltage variation were made in a coal-gas mixt. For safe working, the voltage should be kept as low as possible. It is believed that complete solution lies in a suitable relay system such as will operate the bell perfectly on as low as 0.1 amp. in the relay circuit. It was necessary to raise this current to 0.6 amp. before ignition occurred. The greater safety of a. c. was also demonstrated. KAPP in discussion advised the distribution of condensers along a bare wire system to prevent sparking. S. T. WALKER said he preferred single stroke

signals and explosive-proof cases for a sparking app. Also in *Colliery Guardian* **111**, 66-8(1916).
W. E. RUDER.

Researches on fire-damp. ENRIQUE HAUSER. *Bull. Am. Inst. Mining Eng.* **1916**, 521-34.—In the study of the retardation of the flash point of CH_4 , H. used as the means of ignition wires heated with currents at low potential (4 v.) in order to prevent sparking on fusion, with attendant ignition. He concludes that incandescent filaments may be used as successfully to produce inflammation as the flame or spark provided that the wires are not melted nor oxidized during the period of retardation of explosion.
H. L. OLIN.

Question of ammonia explosions. G. GATTANEO. *Z. ges. Kälteind.* **22**, 3-4 (1915).—The possible causes of several recent accidents in German refrigeration plants are discussed and the necessity of an exptl. investigation of the subject pointed out.

E. C. MCKELVY.

Continuous process of rectification (WONNEBERGER) 16.

Primers. W. H. BUELL. *Brit.*, **21**,082, Oct. 16, 1914. Charging a primer cup or the rim of a rim-fire cartridge with priming compns. containing a detonating azide and a nitrated org. substance, such a mixt. being described in 3,907, 1910. The detonating azides are the salts of heavy metals, especially Pb, Ag and Hg. The nitrated org. substance may be nitrocellulose, nitro-starch, trinitrotoluene, a nitrated carbamide such as nitrourea, or diazoaminobenzene. Substances leaving an alk. residue may be added, namely K_2CO_3 or Na_2CO_3 , $\text{Ba}(\text{NO}_3)_2$ or KNO_3 , or Na, K, or K Co azide. AmOAc may be used to dissolve the nitrocellulose, and glass may be added. KClO_4 , or Ba or K perchlorate, nitrate, or peroxide, may also be added, but preferably not. One example contains 3 parts by wt. of nitrocellulose and 1 part of Pb azide. Another example contains 11 parts of nitrocellulose, 6 parts of Pb azide and 3 parts of Na azide. The specification also describes mixts. of detonating and alk. azides, and mixts. of alk. azides with other substances, such as Sb_2S_3 and KClO_4 .

Primers for small arms. E. RITTER VON HERZ. *Ger.*, 285,902, July 14, 1914. The normal Pb salt of trinitroresorcinol, alone or in combination with O carriers and the usual components of priming compns. are used. Compared with the fulminate compn., these new mixts. are found to have a greater initial velocity and less dispersion. The smoke formation and the fouling of the gun are also less. The Pb compd. of trinitroresorcinol may be used, under certain conditions, for the manuf. of primers, cartridges, and the like. E. g., if upon 1 g. of trinitrotoluene, in a No. 8 shell, about 0.2 g. of the Pb trinitroresorcinol compd. is pressed, followed by 0.15 g. fulminate, the same action is obtained as from the employment of 1 g. trinitrotoluene with the usual covering of 0.555 g. fulminate. These combined cartridge shells are much less affected by moisture than shells with only fulminate covering.

Cartridges for mining and military purposes. C. CLAESSEN. *Ger.*, 284,400, July 5, 1913. Addition to 281,497 (*C. A.* **9**, 1906). Instead of Hg fulminate or a mixt. of Hg fulminate and KClO_4 , other easily ignited and moisture-proof compds. or mixts., such as black powder, gun cotton, smokeless powder, picrates, perchlorate compds., and other flame carriers, may be used. The charges for such cartridges may be made up of 0.85 g. tetryl (tetranitromethylaniline), 0.15 g. Pb_2N_2 , and 0.05 g. K picrate or, instead of the last, 0.10 g. KClO_4 with 20% milk sugar.

Ammunition. C. W. MULLER and J. PATTEN. *Brit.*, 20,969, Oct. 14, 1914. In the manuf. of gun cartridges, arranging at the forward end of the explosive charge a layer or wad of $(\text{NH}_4)_2\text{CO}_3$ or $\text{NH}_4\text{NH}_2\text{CO}_3$ or other like substance, preferably impreg-

nated with paraffin, vaseline, petroleum, jelly, or other oily substance, to cool and lubricate the gun barrel. A further quantity of such materials may also be placed in other parts of the cartridge.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Notes on a new process of bleaching. S. F. PRICKHAM. Brooklyn. *J. Ind. Eng. Chem.* 8, 108-9(1916).—P.'s invention "consists of a process of bleaching by substituting for the usual lime and soda boils a single boil in a soln. of soap, preferably a pure vegetable soap, in which is dissolved a sufficient amt. of C_6H_6 , or its homologs or derivatives as found in the light distillates of some varieties of petroleum, especially that of California, as distinguished from the light distillates of paraffin petroleum. The strength of the soln. in both soap and C_6H_6 would depend upon the kind and character of the material to be bleached, light cotton fabrics requiring less than heavy cottons, and any cotton less than flax, jute, or hemp." For heavy woven flax P. recommends for each 100 lbs. of goods, water 50 gal., soap 10 lbs., C_6H_6 3 gal. After boiling the soap soln. is washed out and the goods bleached in any chemic. P. prefers $NaClO$ made by mixing a 58% soln. of Na_2CO_3 and a soln. of $CaOCl_2$ in the cold and allowing to stand 4 days, a slight excess of Na_2CO_3 being present. Bleaching requires 3-5 hrs. After washing the bleached goods they are soured, washed and calendered as usual. By this method a complete bleach of cotton or linen can be made in 1-2 days. A patent was denied the above process, the Patent Office declaring that "Benzine" and "Benzene" were identical. L. W. RIGGS.

The effect of sulfuric acid in dissolving cellulose. W. ZÄNKER. *Kunststoffe* 6, 17-9(1916).—A general discussion of the effect of acidity of cellulose used in the manuf. of artificial silk, together with a brief review of tests previously published (cf. *C. A.* 8, 1675, 2219; Schwalbe, *C. A.* 1, 1696, 2179). F. W. SMITHER.

Spinning nozzles for the manufacture of artificial silk. K. SÖVERN. *Kunststoffe* 6, 4-7, 19-20(1916).—A description with cuts of patented devices. F. W. S.

Recognition of the commoner adulterants of kapok. E. BELLOLI. *L'industria tessile e tintoria* 16, 208(1915); through *Ann. chim. applicata* 4, 365.—B. discusses in detail the physical, microscopical and microchem. properties of genuine kapok, and gives the methods for distinguishing it from products of less value, especially from akund (*Calotropis gigantea e procera*). S. LEVY.

Oxalic acid substitutes in the laundry. E. D. KÖRPPING. Lockport. *J. Ind. Eng. Chem.* 8, 196(1916).—Among substitutes for $(COOH)_2$ in laundry practice there has been offered an acid sodium fluoride which causes white goods to finish a dirty yellow, the discoloration being increased by repeated washing. The addition of NaF to water containing compds. of Ca, Mg, and Fe causes a pptn. of CaF_2 and MgF_2 which in a gelatinous condition carry down the Fe and hold it in the pores of the fabric. L. W. RIGGS.

Bluish and greenish gray dyes. M. H. ISLER. U. S., 1,169,404, Jan. 25. Nitro or amino derivs. of normal or isodibenzanthrone are treated, in $PhNO_2$, with $AlCl_3$, $SbCl_5$, PCl_5 or PCl_3 . Dark violet-black powders are formed, insol. in H_2O and in dil. acids and alkalis, giving blue-green to red-violet solns. in $PhNO_2$, green-blue to black-blue solns. in quinoline and blue vats with alk. hyposulfite soln., dyeing cotton blue-gray to green-gray fast to Cl.

Blue disazo dye. W. NEELMEIER, H. JORDAN and K. HEUSNER. U. S., 1,169,344, Jan. 25. A dye of the formula $(\text{OCH}_3)(\text{NH}_2)\text{ClC}_6\text{H}_3\text{N}:\text{N}:\text{C}_{10}\text{H}_7(\text{SO}_3\text{H})(\text{OC}_2\text{H}_5)\text{N}:\text{N}:\text{C}_{10}\text{H}_7(\text{SO}_3\text{H})(\text{OH})$ is made by diazotizing and combining 5-amino-4-chloro-2-acetyl-amino-1-phenyl methyl ether, 1-amino-6-sulfo-2-naphthyl ethyl ether and 1-naphthol-4-sulfonic acid. Its Na salt is a dark powder sol. in concd. H_2SO_4 with a bluish color. On cotton it gives blue shades which change to fast greenish blue after diazotization and development with β -naphthol.

Blue-violet dye. M. LATTEN. U. S., 1,169,329, Jan. 25. A dye of the formula $(\text{OH})_2\text{C}_6\text{H}_3\text{N}:\text{N}:\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5)(\text{CH}_3)\text{N}:\text{N}:\text{C}_{10}\text{H}_7(\text{SO}_3\text{H})_2\text{N}:\text{N}:\text{C}_6\text{H}_4(\text{OC}_2\text{H}_5)(\text{CH}_3)\text{N}:\text{N}:\text{C}_6\text{H}_3(\text{OH})_2$ is made by combining the tetraazo compd. of 1,5-naphthalenediamine-3,7-disulfonic acid with 2 mol. proportions of cresidine, further tetraazotizing and combining with 2 mol. proportions of resorcinol. Its alk. salt is a grayish black powder sol. in hot H_2O with a reddish violet and in concd. H_2SO_4 with a greenish blue color. It gives violet shades on cotton which are rendered fast on treatment with CH_3O .

Yarn-dyeing apparatus. J. J. FRARON. U. S., 1,170,440, Feb. 1.

Dyeing artificial silk. F. KUNERT. U. S., 1,169,267, Jan. 25. Artificial silk is dyed by successive treatment with, and combination between, a diazo- or tetraazo- or diazoazo compd., *e. g.*, the diazo compd. derived from *p*-nitro-*o*-toluidine or *m*-aminoazotoluene or *m*-nitro-*o*-anisidine, and an anilide or nitroanilide or other arylide of 2,3-hydroxynaphthoic acid. Non-sulfonated compds. are used to give fast colors. After dyeing, washing and soaping, the material may be treated with HOAc , HCOOH or tartaric acid to brighten the color.

Kier for dyeing. A. KLUGE. Brit., 20,561, Oct. 5, 1914. A kier for dyeing straw, chip, etc., with the usual hooded central uptake tube, has a circulation-producing means below its perforated false bottom, consisting of a steam-coil provided with perforations directed inwards, either horizontally or slightly downwards.

Aniline-black and like dyeing. B. KEEGAN. Brit., 20,467, Oct. 2, 1914. Khaki and like shades are obtained on wool by immersing it in a bath containing *m*-toluylenediamine and a dichromate, and subsequently adding H_2SO_4 . According to an example, the bath contains *m*-toluylenediamine, NaCl , HOAc , and $\text{Na}_2\text{Cr}_2\text{O}_7$, H_2SO_4 being subsequently added and the mixt. brought to the boil. Other agents which on treatment with H_2SO_4 yield an oxidizing agent may be substituted for the dichromate.

Dyeing. G. G. HEPBURN. Brit., 21,052, Oct. 16, 1914. Aniline-black and like dyeing. Shades are produced on wool, alone or mixed with vegetable or other fiber, by treating the wool first in a bath containing aq. HOCl , and then, after washing or not, in a bath containing an org. or inorg. salt of an aromatic amine, *e. g.*, aniline, *m*-phenylenediamine, *p*-diaminodiphenylamine, α - or β -naphthylamine, benzidine, toluidine, dianisidine, or *p*-diaminostilbene.

Dyeing. E. E. M. PAYNE. Brit., 21,087, Oct. 16, 1914. Textile materials, such as wool, silk, cotton, linen, etc., are dyed by means of solns. of humus; the material may be treated with mordants before or after dyeing, and the shades produced may be modified by addition of other dyes, *e. g.*, logwood or indigo-white, to the dye-bath. The humus soln. may be prepd. by leaching peat-moss litter with dil. NaOH soln., pptg. the humus from the resulting liquor by addition of H_2SO_4 , filtering off the ppt., and redissolving it by addition of sufficient NH_3 or other alkali to give a neutral soln. According to an example, wool is dyed a khaki shade by first degreasing, then mordanting with $\text{K}_2\text{Cr}_2\text{O}_7$ and $\text{KHC}_4\text{H}_4\text{O}_6$, or with basic Cr sulfate, FeCl_3 , FeSO_4 , or alum and $\text{KHC}_4\text{H}_4\text{O}_6$, then dyeing in a bath containing humus obtained from peat as described above, with addition of logwood, neutralizing if required by passing through a soln. of borax, and finally treating with a soln. containing soap and oil or a superfatted

soap. When the material is first dyed and then treated with a mordant, the humus soln. should be acidified, *e. g.*, with HOAc; or the material may be treated with a mineral acid prior to dyeing.

Dyeings on vegetable fiber. BADISCHE. Ger., 283,742, and addition 285,230, Feb. 7, and Apr. 4, 1914. Rich dyeings are obtained by combining benzoyl-1,7-aminonaphthol or its derivs. substituted in the benzoyl residue, with unsulfonated diazo-, diazoazo-, or tetrazo compds. According to the addition patent, the *N*-arylsulfo derivs. of 1,7-aminonaphthol are combined with unsulfonated diazo-, diazoazo-, or tetrazo compds.

Dyeings on pelts, hair, feathers. FARBW. v. M. L. & B. Ger., 285,769, Apr. 30, 1914. The material, mordanted or not, is treated with solns. of 1,8-diamino- or 1,8-dihydroxy-, or 1,8-aminohydroxynaphthalene derivs., which contain in each benzene nucleus of the naphthalene, another OH or NH₂ group in the *o*- or *p*-position. Cf. C. A. 10, 394.

Waterproofing textiles. E. GIRZIK. Ger., 286,120, July 4, 1913. Textile materials are impregnated with solns. of cellulose esters and castor oil. Cf. Aust., 3,034, 1913 (C. A. 8, 2229).

Artificial silk and other molded articles. R. ADLER. U. S., 1,169,756, Feb. 1. An ammoniacal soln. of oxycellulose is mixed with an ammoniacal soln. of casein. A transparent ppt. is formed from which artificial silk or molded articles of other character may be made. CH₂O may be used for hardening them.

Purifying wool-scouring liquors. E. V. CHAMBERS, T. C. HAMMOND and G. G. JARMAN. U. S., 1,170,962, Feb. 8. Wash liquor obtained by scouring wool with soap solns. is heated and centrifuged to sep. grease without sepg. soap and alkali and the remaining liquor is prepd. for further use in scouring and freed from excess alkali by treatment with CO₂.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Percentage mixtures of leaded zincs and basic sulfate white lead. J. E. HECKEL. *Drugs, Oils and Paints* 31, 289-91(1916).—Tables and charts are given which enable manufacturers to formulate mixts., containing leaded zincs and sublimed lead sulphate which will contain definite amts. of ZnO and basic sulfate of Pb. E. W. BOUGHTON.

Notes on prepared paints for metal surfaces. H. A. GARDNER. *Drugs, Oils and Paints* 31, 292-3(1916).—Pigments that are basic in nature or that contain the CrO₄ radical prevent rusting of Fe. Specifications for red lead should require 85-90% of Pb₃O₄, the remainder to be practically pure PbO. PbO has a valuable "cementing" action in the paint film. Formulas are given for paints of different colors, to be used on metal. Anti-fouling and anti-corrosive paints for marine use are briefly discussed. When coal tar is used in paint it should be free from NH₃ or H₂O. For painting galvanized Fe, preliminary treatment with a soln. of a Cu salt is proposed. E. W. B.

Paint and varnish industry during 1915. *Drugs, Oils and Paints* 31, 288(1916).—A statement of general conditions. Among other facts it is noted that pigments which require the use of K salts during manufacture, such as Prussian blue and the chromes, have advanced in price. E. W. BOUGHTON.

Ponceau colors in paint. A. COBENZYL. *Farben-Ztg.* 21, 392-3(1916).—Description of the manif. of "satin white," a mixt. of Ca aluminate and CaSO₄, which is used as a base for ponceau lakes. E. W. BOUGHTON.

Ponceau colors in modern varnish manufacture. ANON. *Farben-Ztg.* 21, 346-8 (1916).—General information regarding properties, use, etc. E. W. BOUGHTON.

Linseed oil and other oil varnishes. O. PRAGER. *Seifensieder-Ztg.* 42, 853-4, 893-4, 913, 936-7, 977, 1021-2, 1065-6, 1113-4 (1915).—Discussion of raw materials and methods of manufacture. E. SCHERUBEL.

The use of raw linseed oil in paints. J. F. SACHER. *Farben-Ztg.* 21, 134-5 (1915).—In Germany linseed oil is always bleached before being used for the manufacture of paint, while in England and the U. S. untreated raw linseed oil is extensively used. If raw linseed oil is used its drying properties must be first ascertained. A note by the editor states that the selection of raw oil, boiled oil, or "stand" oil must depend upon the nature of the paint. E. W. BOUGHTON.

Report of Committee D-1 on preservative coatings for structural materials. P. H. WALKER, et al. *Proc. Am. Soc. Testing Materials* 15, Pt. I, 186-272 (1915).—The Committee proposes specifications for raw linseed oil from N. American seed, for raw Chinese wood oil and for boiled linseed from N. American seed, and also proposes standard definitions for terms used in paint specifications (cf. C. A. 9, 2458). A complete report of the Havre de Grace bridge paint tests is given, showing in detail compn. of paints, conditions of application, rating on inspection, etc. A report of coöperative work on Chinese wood oil is given, showing results obtained by the heating test and the I jelly test on pure and adulterated samples. The results obtained by the committee using the "light break" method of Ware and Schemann (cf. C. A. 8, 3244) were not satisfactory. Oils from American grown nuts were very similar to the pure oil from Chinese nuts. A report is given showing the results obtained with paints on steel plates at Atlantic City and the relation of these results to the classification of the pigments as "inhibitive, indeterminate, or stimulative." The results indicate that such classification (by means of the "water test") does not give reliable information regarding the values of the pigments in oil paints. Report of coöperative work on boiled linseed oil is given. Two members of the Committee obtained very concordant results for hexabromides by Eibner's method (cf. C. A. 7, 903). Inspection of the white paint test fence at Washington indicates that composite paints containing both Pb and Zn pigments show superiority to single primary pigment paints. A report on a fungus growth which appeared on some of the panels is given. Report of coöperative work on paint thinners other than turpentine shows the results of coöperative work on evapn. and flash tests. Report on sampling liquids is given (cf. C. A. 9, 2361). The discussion of the report of Committee D-1 contains some changes in the reports of the sub-committees. E. W. BOUGHTON.

Standard specifications for the purity of raw linseed oil from North American seed. *Year Book, Am. Soc. Testing Materials* 1915, 417-9.— $D_{15.5}^{15.5}$, 0.932-0.936; d_{25}^{25} , 0.927-0.931; acid no. (max.), 6.0; sapon. no., 189-195; unsapon. matter (max.), 1.5%; η_{25} , 1.4790-1.4805; I no. (Hanus) (minimum), 180. Methods of testing are given. E. W. BOUGHTON.

Standard specifications for purity of boiled linseed oil from North American seed. *Year Book, Am. Soc. Testing Materials* 1915, 420-22.— $D_{15.5}^{15.5}$, 0.937-0.945; acid no. (max.), 8.0; sapon. no., 189-195; unsapon. matter (max.), 1.5%; η_{25} , 1.479-1.484; I no. (Hanus) (minimum), 178; ash, 0.2-0.7%; Mn (minimum), 0.03%; Ca (max.), 0.3%; Pb (minimum), 0.1%. Methods of testing are given. E. W. BOUGHTON.

Standard specifications for the purity of raw Chinese wood oil. *Year Book, Am. Soc. Testing Materials* 1915, 423-27.— $D_{15.5}^{15.5}$, 0.939-0.943; acid no. (max.), 6.0; sapon. no., 190-195; unsapon. matter (max.), 0.75%; η_{25} , 1.515-1.520; I no. (Hübl 18 hrs.) (minimum), 165; heating test, Browne's method (cf. C. A. 7, 2315) (max.), 12

min.; I jelly test (max.), 4 min. Methods of testing are given. An immersed stem thermometer is recommended for the heating test, and if a long stem thermometer is used the reading must be corrected for emergent stem. The I jelly test is made as follows: In a wide-necked 200-cc. Erlenmeyer flask, place 2.5 g. (wt. correct to 1 mg.) of the oil. Add 10 cc. of CHCl_3 from a pipet and stopper the flask immediately. Carefully insert a small glass vial into the flask so that the vial stands upright. Into the vial from a pipet run 10 cc. of a soln. of I in CHCl_3 , containing 0.035 to 0.036 g. of I per cc. Place the flask in a bath containing water at 25 to 26° and allow it to stand there for a few min. Keep the flask stoppered, except when it is necessary to remove it to insert the vial and to add the I soln. Tilt and rotate the flask so that the vial is upset and the contents of the flask are thoroughly mixed, at the same time starting a stop watch. Keep the flask in the bath at 25 to 26° and at the end of every quarter min. tilt the flask towards a horizontal position. Note the time required for the formation of a jelly that does not flow, but sticks to the bottom of the flask or slides as a mass. Record time in minutes and quarters thereof. Pure Chinese wood oil should require $2\frac{3}{4}$ to $3\frac{1}{4}$ min. for the formation of the jelly. If the temp. of the laboratory is more than 2° or 3° above or below 25°, place the flask containing the I soln. in the bath and allow it to remain there for several minutes before pipetting out the 10 cc. for the test.

E. W. BOUGHTON.

Standard specifications for turpentine. *Year Book, Am. Soc. Testing Materials* 1915, 428-30.—A revision of proposed specifications (cf. C. A. 8, 3503). The specifications apply to either gum spirits or wood turpentine. Color shall be "standard" or better. Turpentine must be clear and free from suspended matter, and water. $D_{18.8}^{18.8}$, 0.862-0.872; $n_{18.8}^{18.8}$, 1.468-1.478; initial b. p., 150-160°; 90% of the turpentine shall distil below 170°; the polymerization residue shall not exceed 2% and its $n_{18.8}^{18.8}$ shall not be less than 1.500. Methods of analysis are given.

E. W. BOUGHTON.

The analysis of boiled linseed oil. W. FAHRION. *Farben-Ztg.* 21, 88(1915).—A continuation of the discussion of the nomenclature of resinate and linoleate boiled oil. Cf. C. A. 9, 1848.

E. W. BOUGHTON.

Condensation products of nitroaniline and formaldehyde and their use in varnish. ANON. *Farben-Ztg.* 21, 63-4, 86-7, 113-4(1915).—An extensive review.

E. W. BOUGHTON.

The resistance of modern enamels and varnishes to chemical agents. KRUMHAAER. *Farben-Ztg.* 21, 336-8, 390-2(1916).—A consideration of the properties required for enamels and varnishes for different purposes, such as marine varnishes, automobile enamels, etc.

E. W. BOUGHTON.

Physical and chemical characteristics of the most important resins used in the varnish industry. ANON. *Farben-Ztg.* 21, 325-6, 350-1, 367-70(1916).—A compilation of data.

E. W. BOUGHTON.

Glass etching inks 19. Artificial insulating materials 4.

Pigment. H. A. GARDNER. U. S., 1,169,253, Jan. 25. A mixt. of basic Pb carbonate and BaCO_3 is formed by reacting with CO_2 or Na_2SO_4 or Na_2CO_3 upon a soln. or suspension of basic Pb acetate and Ba(OH)_2 or other Pb and Ba compds.

Zinc sulfide pigment. C. RANSON. U. S., 1,171,246, Feb. 8. Zn sulfide containing combined Zn oxide is freed from the latter (1) by heating under pressure with a small excess of NH_4SH at 135°, or (2) by heating with a 6-8% soln. of HCl or HF (followed by washing with alkalis to eliminate ZnCl_2 , if HCl is used), or (3) by calcining at 600-700° with 5% of S and 1-2% of Na silicofluoride or fluosilicate.

Paints. INTERNATIONAL COLOR and CHEM. CO., INC. Ger., 285,968, Jan. 27, 1914. Paints and similar colors are obtained by combining a pigment, in the presence of H_2O , with a metal soap and a color vehicle. Cf. Fr., 467,464 (C. A. 9, 2001).

Anti-rust coating. B. ZSCHÖKKE. Ger., 285,708, May 30, 1914. Addition to 276,122 (C. A. 9, 530). For the fat or oil vehicle specified in the principal patent for the chromic acid soln., can be substituted inorganic and organic adhesives, binders, and coating masses of all kinds, such as water-glass, cements, gypsum, tar, dextrin, resins, water colors, and the like. By using glue colors the further advantage is secured that the chromic acid and its salts harden the lime substance, so that such colors are not only anti-rust, but also, to a certain extent, waterproof. E. g., 100 parts of permanent white ($BaSO_4$) and 5 of lime powder are rubbed to a paste with 80 parts of a 10% $K_2Cr_2O_7$ soln., or 100 parts of tar containing H_2O are mixed with a 5% aq. soln. of Na_2CrO_4 at the ordinary temp.

Coating steel. G. D. FRIDT. Brit., 20,621, Oct. 6, 1914. Steel surfaces are prevented from rusting beneath a coating of paint by a preliminary treatment with an alc. soln. of H_3PO_4 . The soln. may be applied with a brush, or by dipping, and incrustations of rust may be removed by rubbing with an emery cloth in the presence of the soln.

Tar paint. J. W. DUNFORD. U. S., 1,170,883, Feb. 8. Coal tar 25 gals., is mixed with oil of tar 25 gals., graphite 25 lbs., linseed oil 5 gals., yellow ochre 15 lbs., Fe oxide 20 lbs., oil of turpentine 5 gals., slate ground in linseed oil 20 lbs., and pine tar 10 gals., to form a paint for use on roofs, bridges, etc.

Filler and "graining ground" for use on wood or metal. C. F. COOPER. U. S., 1,169,930, Feb. 1. Zn white 50, is mixed with another dry pigment such as ochre or PbO 40, shellac 5 and alc. 5 parts.

Varnish-paint or "graining ground" for use on metals. C. F. COOPER. U. S., 1,169,931, Feb. 1. A dry pigment 42-50, is mixed with CaO 13-17, varnish 13-17, turpentine 12-18 and $NaCl$ 2%.

Paint- and varnish-remover. C. ELLIS. U. S., 1,169,783, Feb. 1. Benzyl alc 30, is mixed with benzyl acetate 25, cresylic acid 5, solvent naphtha of high b. p. 40, CCl_4 15 and paraffin 5 parts. Benzaldehyde, Me phthalate, benzyl cresylate, and thickening agents such as starch, infusorial earth and whiting, are specified in other formulas.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

The hydrogenation of oils and fatty compounds. G. F. JAUBERT. *Rev. Ges. Chem.* 18, 117-33, 144-60(1915).—An outline of the whole industry including a discussion of catalysis, the production of hydrogen and the hydrogenation of fats, etc. Part 2 is a detailed description, with drawings of all processes and patents used by the 27 largest concerns in the world.

L. H. CHERNOFF.

Refining vegetable oils. C. BASKERVILLE. *J. Ind. Eng. Chem.* 8, 118-21(1916).—B.'s process is as follows: Two % of prepared cellulose, a suitable amt. of $NaOH$ (stronger than ordinarily used) and a detd. amt. of Na_2CO_3 are added to the oil and the whole agitated while it is being heated to 45-64° to produce the break, after which it is filtered. If linters are used, 1/4 to 1/2% of the dry cellulose is added. E. S.

Thermal values of fats and oils. I. Heat of bromination. J. W. MARDEN. *J. Ind. Eng. Chem.* 8, 121-6(1916).—A special app. was devised to det. the heat of bromination consisting of a specially constructed mixing chamber placed in H_2O contd. in the

ordinary form of H_2O calorimeter or in a Dewar tube. The heats of bromination in calories per g. of oil were detd. on a number of oils and these values compared with the I nos. The heat of bromination is not directly comparable to the I no. The heats of soln. of Br and most oils in CCl_4 are very small.

E. SCHERUBEL.

Northern fur seal oil. M. TSUJIMOTO. *J. Chem. Ind. Japan* 18, 798-808(1915).—This seal is found on Robbin Island off the eastern side of Karafuto, Japan. Three samples were examd.: (1) and (2) were body oils and (3) foot oil. The consts. for (1), (2) and (3), resp., were as follows: d_{15} 0.9256, 0.9251, 0.9356; acid no. 1.02, 1.65, 20.0; sapon. no. 188, 186, 195; I no. 155, 157, 133; n_{20} 1.4783, 1.4790, 1.4772; butyrefractometer at 20°, 79.9, 81.2, 78.0; unsaponifiable matter 0.62%, —, —; oxidized acids 0.12%, —, —; m. p. of fatty acids 26°, 28-9°, 33°; polybromide 43.2%, —, 24.85%; Br content of polybromide 69.83%, —, 69.48%. These bromides do not melt but decompose at about 250°. This property corresponds to that of the bromides of other marine animal oils.

E. SCHERUBEL.

"Soy" and "sake" oils. M. TSUJIMOTO AND T. UENO. *J. Chem. Ind. Japan* 18, 1072-7(1915).—These oils are by-products of the soy and sake brewing industry. "Soy" oil is obtained from a mixt. of soy beans and wheat together with aromatic and decompn. products. The yield of the oils is small, being about 0.25 to 0.30% for "soy" and 0.01 to 0.02% by vol. for "sake" oil. "Soy" oil is best refined by reducing with Zn dust and H_2SO_4 and then treating with Kambara earth. It can then be used in the manuf. of soap. "Sake" oil has not been prepared commercially. The consts. of "soy" and "sake" oils, resp., are: d_{15} 0.9000, 0.9031; solidification p. -3°, turbid at 0°; acid no. 59, 22.5; sapon. no. 184, 179; I no. 128, 101; n_{20} 1.4650, 1.4660; unsapon. matter 2.88%, —.

E. SCHERUBEL.

Yeast fat. O. NEUSS. *Seifensfabr.* 36, 38(1916).—Dr. Lindner found a yeast plant contg. 18% fat on the dry basis. By propagating this at 20° upon a cloth in large iron pans the product may be readily removed, pressed and dried. A fat content as high as 50% on the dry basis has been obtained. The fat is similar to olive oil and makes a good curd soap.

E. SCHERUBEL.

The Wijs iodine solution. S. UENO. *J. Chem. Ind. Japan* 19, 30(1916).—U. concludes from exptl. work that: (1) The soln. prepd. by the formula given by Holde, Ubbelohde, and Marcusson (7.1374 g. I and 39.3573 g. ICl_3) is not unfit for the detn. of I value, notwithstanding excess of Cl. (2) I values obtained with solns. prepd. as above and as per Lewkowitsch (8.6676 g. I and 7.9617 g. ICl_3 , correct proportions by calcn.) practically agree with that obtained with the "normal" soln. (prepd. from I and Cl) on the day of prepn., after 1 week, and after 2 weeks. (3) An old Wijs soln. gives a slightly lower I value. (4) A fair excess of Cl in the Wijs soln. tends to give high I values which approach the normal after a time (in days) proportional to the excess value. A moderate excess of I has practically no effect on the detn. of I value. (5) The I values of Chinese and Japanese wood oils obtained with an old Wijs soln. are lower than normal, but can be increased to normal by prolonging the time of absorption. The deep reddish brown color produced on mixing Wijs soln. with wood oil is not due to photochemical influence. Examn. of the iodo-chloride of the fatty acids of wood oil shows that more Cl is absorbed than corresponds to the formula ICl_3 .

F. W. SMITHER.

The Uba cane grown in Natal and the extraction of the wax from it. WM. CLACHER. *Intern. Sugar J.* 18, 22-3(1916).—A description is given of the Uba cane. The wax is extd. from the filter press cake (which contains from 14 to 17%) by the benzene process. The cane wax is sol. in kerosene which on cooling deposits the wax as a pale yellow sediment. As the benzene process is expensive, the method used for removing wax from shale oil by freezing is recommended.

A. GROSS.

The use of lignite for the manufacture of montan wax. RUD. MATTHIAE. *Grimma. Chem. App.* 3, 1-3, 13-5(1916).—Plans of plant, list of necessary app., costs and profits, and directions for operating are given. J. H. MOORE.

The sampling and analysis of beeswax. M. S. SALAMON. *J. Soc. Chem. Ind.* 35, 8-10(1916).—S. emphasizes the necessity of securing true samples. With a piece of refined beeswax, it is best to take shavings from each corner and also from the center of the block on both sides, as a mixture of waxes has a tendency to settle out in layers on cooling. In prepg. wharf samples, the amt. of the sample being too large (sometimes as much as 30 lbs.) to melt in lab. vessels, it is best to take the shavings (with a potato parer) from each piece and melt these. It is often best to halve the original wharf sample (consisting of a lot of pieces) and prep. a sample from each half, analyzing the 2 samples separately. The usual detns. of acid value, ester value, etc., should be supplemented by qualitative tests, particularly directed to the presence or absence of paraffin wax, and if necessary a detn. of hydrocarbons. In applying the Weinwurm test for paraffin, it is not sufficient merely to note whether the soln. is clear or cloudy; unless distinct flakes are observed, no conclusion should be come to without further tests. Certain hard waxes, such as Chilian and Egyptian, give a clear soln. even when 5% of paraffin wax is present, while other waxes, such as Madagascar and Abyssinian, will give a slightly cloudy soln. even when pure. It is always best to prepare a further sample of wax to which 5% of paraffin wax has been added: if the original wax was adulterated with paraffin wax distinct flakes will then usually be seen in the Weinwurm soln. obtained from this prepd. sample. If these flakes are not observed it may be concluded that the original sample was free from paraffin wax providing the ester nq. was normal. In any case a clouding point test should always also be applied for confirmation. A table is given of the characteristics of the various varieties of beeswax, showing the av., max., and min. figures obtained in the analysis of over 500 commercial wharf samples. The m. p. detns. were made in capillary tubes closed at one end. There appear to be 2 distinct types of Abyssinian beeswax; one is dark red in color and has an av. acid value of 20 and ester value 76, while the other is pale in color and has an acid value of 18 and an ester value of 73. Cf. C. A. 9, 2322.

F. W. SMITHER.

Toilet soap base. B. ZIENLE. *Seifensieder-Ztg.* 42, 1057-8(1915).—Much lower grade fats are now used for toilet soap and about 5% of light colored rosin is added to increase lather and cover odor.

E. SCHERUBEL.

Toilet base from cheap fat. T. M. *Seifensieder-Ztg.* 42, 1081-2, 1106-7(1915).—By handling cheap fats according to the Krebitz process a satisfactory toilet base can be made.

E. SCHERUBEL.

Determination of active oxygen in washing materials. A. GRÜN AND J. JUNG-MANN. *Seifenfabr.* 36, 53-5(1916).—The ordinary methods of titrating active O by means of KMnO_4 , do not give correct results where oxidizable matter is present. The iodometric method gives better results and is recommended.

E. SCHERUBEL.

Fat content and deterative value of soaps. BERGO. *Seifensieder-Ztg.* 42, 1105-6(1915).—Owing to the scarcity of raw materials since the war it is no longer desirable to manufacture soaps of high fat content, and it is advocated to fill soaps so as to reduce the fat content to 40 or 50%. Another suggestion put forth is to incorporate fat solvents such as C_6H_6 , CCl_4 or naphtha which will save soap.

E. SCHERUBEL.

Liquid soaps. MAX DOENHARDT. *Pharm. Ztg.* 60, 847(1915).—Most liquid soaps, both potash and tar, become opaque, thicken or sep. when subjected to cold. In order to obviate such tendency in the case of tar soap, the following formula is suggested as yielding a completely H_2O -sol. prepn. and one immune to cold: Ol. rusci

25, Liq. kalii caustici (35%) rec. paratur 18, Ol. rapae 20, Spiritus 25, Aq. destillata 12. Birch tar is first mixed with the KOH soln., the rape oil added, then saponified and the mixt. dissolved in alc.

W. O. E.

Soap preparations containing sucrose. J. BOES AND H. WEYLAND. *Chem. Ind.* 38, 447-54(1915).—A review and discussion of the patent claims, literature, etc., together with exptl. data on solid and liquid soap of known compn. from which it is concluded: (1) The service-value of a soap is detd. by the ratio of detergent power to injurious effect. (2) The detergent value is best ascertained not through chem. analysis (fatty acid content, free alkali, etc.), but by a detn. of the lathering power and the internal friction or hardness. (3) The caustic action of free alkali may not be considered as a detergent effect, but as a colloidal chem. process in which adsorption compds. are formed. (4) The chemical detergent effect of free alkali and its action on goods, colors, etc., depend solely upon its OH-ion concn. (5) Non-dissociated alkali sucrate as well as sucrose have no detergent value. (6) The addition of free alkali to soap and its subsequent partial neutralization with sucrose are based on false premises. (7) The sucrose soap studied showed no advantageous properties, the low-lathering power and the small inner friction or hardness being decided disadvantages. (8) The demonstrated small service-value of sucrose soap excludes its use as a substitute for ordinary Na soap.

Report of Committee D-2 on standard tests for lubricants 22.

Hydrogenating fatty compounds. E. B. HIGGINS. U. S., 1,170,814, Feb. 8. Fatty acids or other unsatd. compds. to be hydrogenated are mixed with a formate, preferably Ni or Zn formate, and another catalytic material, e. g., PdCl₂, and heated in an inert atm. or in H₂ to effect hydrogenation.

Refining cottonseed oil. G. M. HOLBROOK. U. S., 1,169,154, Jan. 25. Crude cottonseed oil containing about 1% of free fatty acids is treated with 4% its wt. of an 18° Bé. NaOH soln. and 0.75% its wt. of a 44° Bé. Na silicate soln. and agitated and gradually heated to cause the soap stock to settle.

Refining cottonseed oil. G. M. HOLBROOK. U. S., 1,169,155, Jan. 25. Crude cottonseed oil containing about 1% of free fatty acids is agitated with about 1% its wt. of an 18° Bé. NaOH soln. to neutralize the acid, then 3% of the same soln. is added together with 0.75% of a 44° Bé. Na silicate soln., the oil is agitated and heated to about 45° and the soap stock formed is sepd. from the oil.

Saponifier. E. TWITCHELL. U. S., 1,170,468, Feb. 1. A saponifier for liberating fatty acids and glycerol from fats and oils is formed by treating crude "naphthalene-stearo-sulfonic acid" with NaCl soln. to wash out impurities, at the same time converting part of the sulfonic acid into the Na salt, washing out fatty impurities with naphtha, dissolving the product in a large amt. of H₂O and adding a compd. of Ba, Ca, Sr or Mg to ppt. the insol. alk. earth salt of the acid. The ppt. is dried and ground and forms a highly concd., stable saponifying agent.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

Action of copper solutions on sucrose. Determination of invert sugar in the presence of sucrose. E. SAILLARD. *Compt. rend.* 161, 591-3(1915).—In the detn. of reducing sugar by the use of alk. Cu tartrate soln. the presence of sucrose in the soln. causes more Cu to be reduced than the amt. of invert sugar present would other-

wise produce. The amt. of this increased reduction depends on the concn. of sucrose, reducing sugar, and Cu soln., and on the manner of heating. High temps. cause more reduction than moderate heat. S. has evolved a method using a somewhat less alk. Cu soln. and heating to 64° for 22 min. Tables showing the amts. of Cu reduced by various amts. of invert sugar and the increase due to various amts. of sucrose have been worked out for these conditions. The increased reduction is appreciably less than in the usual 2 min. boiling procedure. The amt. of reducing sugar has a very marked influence on the action of the sucrose. If large amts. of reducing sugar are present there is little action due to sucrose. When the amt. of reducing sugar is nearly equiv. to the Cu in the soln. the reduction due to sucrose is practically zero. No explanation is given. An adaptation of the above outlined method applicable for the detn. of reducing sugar in beets, sirups, sugars, and molasses is as follows: Clarify a normal soln. of the sample with $\text{Pb}(\text{OAc})_2$. Remove Pb with dry Na_2CO_3 , filter, and det. reducing sugars using the special solns. with heat for 22 min. at $63-4^{\circ}$. Filter the Cu on an Allihn tube and det. by Bertrand's method. Find the corresponding wt. of reducing sugar by consulting the table.

H. R. SMITH.

Action of sucrose on cupropotassic solutions. L. MAQUENNE. *Compt. rend.* 161, 617-23(1915).—A series of expts. to establish the effect of sucrose alone on alk. Cu tartrate solns. was carried out. A const. vol. of the Cu soln. was made up with water to a const. vol. after the addition of varying wts. of pure sucrose and this mixt. was heated in a uniform manner. It was found that for increasing per cents of sucrose the amt. of Cu reduced increased rapidly to a max. and then gradually diminished. It was impossible to add enough sucrose to reduce all of the Cu. With about 50% of sucrose in the mixt. under these particular conditions only about $\frac{1}{4}$ of the Cu was reduced. It is thought that complex sucrates of Cu and K are formed, whose coeff. of dissociation decreases as the concn. of sucrose increases; this action diminishes the strength of the alk. Cu tartrate soln. It is noted that in contrast to this slow action, the action of reducing sugars on alk. Cu solns. is very rapid. This shows that the reducing action of sucrose alone is not due to a preliminary hydrolysis to invert sugar but is a direct function of the sucrose mol. It was found impossible to establish a simple relation between the reducing power of sucrose and of invert. On detg. the reducing sugars in a soln. containing also sucrose, when the ratio of sucrose to invert is small the reduction will be less than the sum of the actions on each one alone under the same conditions. This is explained by the fact that the action of reducing sugar on the alk. Cu soln. is very quick and hence the strength of the Cu soln. is diminished before appreciable action has taken place on the sucrose. This weaker Cu soln. causes less reduction due to sucrose. But when the ratio of sucrose to reducing sugar is large, the total reduction is greater than can be accounted for by the two factors separately. Saillard states that under these conditions sucrates predominate in the soln. and these sucrates acting on the invert sugar like salts of Cu with a weak acid produce a greater amt. of Cu_2O in the same way that CuK carbonate acts in the Soldaini soln.

H. R. SMITH.

The determination of crystallizable sugar by invertin. H. PELLET. *Ann. chim. anal.* 20, 121-2(1915).—A preliminary note, with some general discussion.

P. M. GIESY.

New method for the determination of reducing sugars. E. SAILLARD. *J. fabr. sucre* 56, No. 3, 1(1915).—The usual methods using alk. Cu solns. introduce an error when sucrose is present. This is due to the action of the alkali in boiling soln. causing some of the sucrose to hydrolyze to reducing sugars. S. uses a weakly alk. Cu soln. and heats to only $63-4^{\circ}$ for 22 min. Under these conditions much less sucrose is hydrolyzed and all of the reducing sugar originally present will have thrown down the

equiv. amts. of Cu_2O . The Cu_2O is filtered using an Allihn tube, washed with warm water, and the Cu dissolved in a soln. containing 50 g. $\text{Fe}_2(\text{SO}_4)_3$ and 200 g. H_2SO_4 per l. The tube is washed with water and the entire soln. titrated with KMnO_4 soln. (1 cc. = 10 mg. Cu). A special table to fit these new solns. and conditions has been prepared so that the amts. of reducing sugar for each detd. wt. of Cu pptd. may be quickly ascertained. This method is now in use at the lab. of the Syndicate of Sugar Manufacturers.

H. R. SMITH.
